THE twenty-fourth annual Exhibition of this now widely patronised Society was held on Friday last, the 26th ult. in the park of Sandy Place, and the Committee are to be congratulated on having been able, through the kindness of Mrs. Foster, to revert to the old and unsurpassable site for such an exhibition. A considerable improvement in the arrangements was inaugurated, as the horticultural part of the entertainment was on this occasion more fully detached from the dog, poultry and bird department, which also forms an important and attractive feature at Sandy. Perhaps the one great drawback is the utter impossibility of getting a good general survey of the whole of this interesting and instructive natural history collection in the too limited period of six hours, and bearing in mind that shows of this magnitude and comprehensiveness are hardly meant now as mere displays, but are actually sought out for purposes of study and information, as well as for business purposes, by the various fanciers as well as horticulturists, it would be a public boon could the Committee see its way to keeping the show open two days instead of one, and especially as the second day would probably prove an insurance against a possible wet day as well as remunerative, and it seems a pity that so large a collection should at such great trouble and expense have to be distributed in a few hours. A large gathering was the result on Friday, the day being beautifully fine, and visitors came from all the surrounding counties. Sandy is very well placed for such an exhibition, and no less than £273 was realised at the gates. In most departments, especially in the plant tent, there was a material advance, and no finer display has been seen there.

In the open class for ten stove and greenhouse plants in flower, Mr. J. Cypher, Cheltenham, was easily first with very fine specimens of *Allamanda grandiflora*, *Anthurium Andreanum*, *Clerodendron Balfourianum*, *Bougainvillea glabra*, *Statice profusa*, and *Ericas Eweriana*, *Marnockiana*, *obolata purpurea*, and *atomaria*. For second, Mr. Finch, gardener to H. Marriott, Esq., Coventry, had excellent but somewhat

smaller plants, including good specimens of *Ixoras Fraseri* and *Duffi*, and *Erica Marnockiana*. Mr. G. Redman, gardener to J. H. Goodgames, Esq., Eynesbury, St. Neots, showed well as third. Mr. Redman was first with a tastefully arranged group, and Mr. G. Claydon, gardener to Mrs. Astell, Woodbury Hall, second. For six foliage plants Mr. Claydon was first, including *Crotons* *Queen Victoria*, *Andreanum* and *undulatum*, and *Asparagus tenuissimus*. Mr. Redman was here second, and Mr. W. J. Empson, gardener to Mrs. Wingfield, Ampthill House, third. For six plants in flower Mr. Claydon was again first. For twelve Zonal *Pelargoniums* in the open class Mr. Redman was first with a very even and well-flowered lot. Mr. C. T. Leeds-Smith, Sandy, was first for hardy Ferns and a specimen flowering plant, and Mr. Claydon for stove and greenhouse Ferns. For hybrid *Begonias*, Mr. W. Green, Sandy, was first, and Mr. E. Leeds-Smith, second.

In the open class for forty-eight Roses, not less than twenty-four distinct varieties, there was a strong competition and a good display, Messrs. Harkness & Co., Bedale, leading with very fresh and clean blooms of more than the average size for the season, staging several fine blooms of Mrs. Jno. Laing, evidencing the value of this variety as an autumnal bloomer, *Gustave Piganeau*, *Suzanne Marie Rodocanachi*, *Charles Lefebvre*, *Beauty of Waltham*, *Horace Vernet*, Dr. Andry, A. K. Williams, Sir Rowland Hill, Alfred Colomb, Duchess of Edinburgh, and A. Rigotard. Messrs. G. & W. H. Burch, Peterborough, were well second, having fine flowers of *Comtesse de Nadaillac*, *Etoile de Lyon*, *Horace Vernet*, *Victor Hugo*, *Xavier Olibo*, and *Reynolds Hole*. Mr. H. Frettingham, Beeston, Notts, was third. For twenty-four cut Roses in the amateurs' division, Mr. J. Parker, Hitchin, was first; Mr. A. Burgess, Wimpole, Reyston, second; and M. W. Bourne, Cambridge, third. For six Roses Mr. G. Moules, Hitchin, was first, and Mr. C. Bright, Cambridge, third.

For twenty-four Show Dahlias, distinct, open, Mr. G. Humphreys, King's Langton, Chippenham, was first. For twelve ditto, amateurs, Mr. R. Burgin, Eynesbury, won. Cactus Dahlias were an attractive and interesting display. Messrs. Burrell & Co., Cambridge, showed a well staged and varied collection of twelve bunches, containing *Black Prince*, *Amphion*, *Marchioness of Bute*, *Empress of India*, H. Cannell, Mrs. G. Reed, Professor Baldwin, Mrs. Hawkins, Juarez, and A. W. Tait, and were awarded first prize. Messrs. Paul & Son, Old Nurseries, Cheshunt, were second, having *Charming Bride*, *Cochineal*, Mrs. Jekyll, *Prince Alexander*, and *Duke of Clarence*, all pretty and distinct. For twelve bunches of Pompon Dahlias Mr. G. Humphreys was first, Messrs. Burrell & Co. second, and Messrs. Paul & Son third. For twelve single Dahlias Mr. E. T. Leeds-Smith was the leader. Cut herbaceous and bulbous flowers, strictly hardy and distinct varieties, formed a very attractive feature, Messrs. Burrell & Co. leading with large and well-displayed bunches, including *Rudbeckia purpurea*, *Scabiosa caucasica*, *Gladiolus Marie Lemoine*, G. Baroness Burdett Coutts, *Helianthus multiflorus plenus*, *Tigridia grandiflora alba*, and *Montbretia crocosmæflora*. Messrs. Laxton Bros., Bedford, were a close second, having an effective and well-arranged collection, their most striking kinds being *Lilium Batemani*, *Scabiosa caucasica*, *Phlox coccineum*, *Helianthus Soleil d'Or* and *Multiflorus major*, *Coreopsis lanceolata*, and *Gaillardia grandiflora*. Messrs. Paul & Son were third, having *Montbretia Pottsi*, *Statice latifolia*, *Lilium tigrinum splendens*, and *Gladiolus purpureo auratus*.

For twenty-four Gladioli, not less than eighteen varieties, Messrs. Burrell & Co. were to the front with several fine seedlings of their own, also Baroness Burdett Coutts, a bold and bright flower, rosy carmine; *Primatrice*, *Enchanteresse*, A. Brongniart, *Formosa*, *Pasteur*, *Cervantes*, *Sorcerer*, *Pyramid*, &c. Mr. E. B. Lindsell, Beeston, Hitchin, the successful amateur Rose grower, was a very respectable second with clean and well-developed spikes of the leading varieties; Mr. Bourne, Cambridge, being third. Asters were good for the season, the principal prizes falling to Mr. Burgess, Mr. Bourne leading for very fine African *Marigolds* and *Zinnias*, and for a collection of twelve cut herbaceous flowers, and Dr. Swain, Arlesey, for *Pentstemons*.

Fruit was barely an average show, the season being somewhat untoward for the hardy sorts. Especially was this noticeable as regards Pears. The competition, however, in the classes for Grapes and collections was well sustained. For eight distinct kinds Mr. L. James, gardener to the Rev. S. G. Cotton-Brown, Walkern Hall, Stevenage, carried off the first prize, and with it the silver medal, having good examples of *Black Hamburgh* and *Foster's Seedling Grapes* (the latter not quite in perfect finish), *Golden Queen Melon*, very fine; *Violette Hâtive* Peaches, *Humboldt Nectarine*, *Moorpark Apricots*, *Jargonelle* Pears, and *Duchess of Oldenburg Apples*. Mr. G. Allis, gardener to Major Shuttleworth, Old Warden Park, Beds, was second, only a few points behind, with very fine Grapes, *Alicantes* and *Foster's*, both well finished; *Melon*, *Figs*, *Peaches*, *Apricots*, *Pears*, and *Cherries*. Mr. J. Empson secured third place, and Mr. R. Carter, gardener to Capt. Duncombe, Waresley Park, fourth. For the collection of six distinct kinds Mr. A. Burgess, gardener to the Earl of Hardwick, Wimpole Hall, Cambs, was first, Mr. Redman second, and Mr. R. Brown, Somersham, Hunts, third. For two bunches of *Black Hamburgh Grapes* Mr. W. H. Murfin, Great Staughton, Hunts, and Mr. C. Moore, St. Neots, were respectively first and second. For other black Grapes, two bunches, Mr. Empson was first with very fine *Muscat Hamburgh*, and Mr. Allis second with excellent *Alicantes*. For two bunches of white *Muscats* Mr. Empson was again first and Mr. C. Forbes, Cambridge, second. For two bunches of other white Grapes Mr. Empson was first with large bunches of *Foster's Seedling*, and Mr. Allis second with smaller but

very well finished bunches of the same variety. Mr. J. Myers, gardener to the Earl of Sandwich, Hinchinbrook House, was first for *Peaches*, Mr. Allis for *Nectarines*, Mr. R. Carter for a green-fleshed *Melon*, and Mr. James for scarlet-fleshed *Lord Beaconsfield*.

Vegetables were a large and satisfactory display, the Potatoes and Peas being excellent. Mr. J. Simkins of Shillington, Beds, showed finely in several of these classes, his dish of twelve white kidneys (*Sutton's Satisfaction*) being perfect. Mr. Simkins was also first in the classes for twelve white rounds with *Windsor Castle*, for twelve coloured rounds with *The Dean*, for twelve coloured kidneys with *Prizetaker*, and also for a collection of six varieties, consisting of *Sutton's Seedling*, *Chancellor*, *Satisfaction*, *Reading Russet*, and *Pink Perfection*. Mr. Simkins likewise took first prize for twenty-four pods of *Perfection Peas*, and Mr. Allis for *Broad Beans*. The vegetables in collections of twelve varieties were well contested, Mr. F. Faint of Hertford leading with excellent *Satisfaction* and *Prizetaker* Potatoes, also *Ailsa Craig Onions*, *Fillbasket Pea*, *Carrots*, *Turnips*, *Beet*, *French Beans*, *Perfection Tomatoes*, *Celery*, and *Cucumbers*. Mr. Empson was a good second. For six varieties of vegetables Mr. R. Carter was first, and Mr. W. Bourne second. Very good *Globe Onions* from Mr. Myers were awarded first, but the *White Spanish* were not nearly so good as usual, and this was also evident in the market gardeners' tent where roots and vegetables, although good, showed the effects of the cold checks of last spring.

EARL'S COURT.—AUGUST 26TH AND 27TH.

THE Fruit Show in connection with the International Exhibition was looked forward to with considerable interest by persons interested in the subject of fruit culture under glass or in the open air. Excellent prizes were offered in the schedule for collections of fruit, also good ones for Grapes, Pine Apples, Figs, Peaches, and Nectarines, duly proportioned amounts being provided for Apples, Pears, and Plums. Tomatoes were also included in the schedule, but were not admissible in the collections of fruit. The response made by exhibitors was gratifying, and the Show was worthy of the efforts made to produce it. Twenty collections, comprising 220 dishes of fruit, were staged, the competition being very close between several of the exhibitors, while in some of the Grape classes there was a keen struggle for the coveted honours. All other kinds of fruit were well represented, and the splendid Vines in pots from Berkhamstead, fruit trees from Sawbridgeworth, Waltham Cross, and Crawley, with large market collections of fruit, contributed to the general display. A brilliant group of *Begonias* from Forest Hill, with tall Palms from Messrs. E. D. Shuttleworth & Co., and other miscellaneous exhibits referred to at the end of this report, added to the attractiveness of the two Exhibition buildings. The exhibits were well arranged by Mr. R. Dean and his assistants, and the Judges commenced their duties very soon after the appointed time. In referring to the classes it will be convenient to follow the order of the schedule.

COLLECTIONS.—Class 1, "Collection of fruit, not less than twenty dishes. In this collection four varieties of Grapes (two white, two black—two bunches of each variety), two Pines, two Melons, two dishes of Peaches, two of Nectarines, two of Plums are required. Remainder to be distinct." The terms are quoted for the purpose of making a subsequent reference. As above indicated, three collections were placed in competition. Mr. J. McIndoe, gardener to Sir J. W. Pease, Bart., Hutton Hall, was the premier exhibitor, winning the leading prize, £12, with a magnificent collection of fruit beautifully staged, certainly one of the best that has been seen in any Show. It consisted of handsome *Gros Maroc* and very good *Black Hamburgh*, with clear and fine *Golden Champion* and *Duke of Buccleuch Grapes*, fairly good *Charlotte Rothschild* and *Queen Pines*, a noble pair of Melons—*Exquisite* and *Best of All*, excellent *Golden Eagle* and *Violette Hâtive* Peaches, also *Humboldt* and *Stanwick Elruge Nectarines*, with very fine dishes of *Kirke's* and *Magnum Bonum Plums*. The remaining dishes consisted of *Williams' Bon Chrétien* and *Souvenir du Congrès Pears* (fine), *Brown Turkey* and *Negro Largo Figs* (good), *Duchess of Gloucester* and *Duchess of Oldenburg Apples*, *Bigarreau Napoleon* and *Late Duke Cherries*, *Exquisite Oranges*, *Imperial Lemons*, very fine *Apricots*, a splendid dish of *Noble Strawberries*, *Whinham's Industry Gooseberries*, fine *Red* and *White Currants*, and a good dish of *Passiflora edulis*, altogether thirty dishes, and every one fit for the table of a prince. As will be seen by the conditions, the collection was not limited to twenty dishes, and only in one respect was the specification faulty. After enumerating the "kinds" of fruit that must be shown, the remaining dishes were to be "distinct," but whether distinct "kinds" or "varieties" was not stated. The addition of one of those words would have made all clear. As it was, the other exhibitors not unnaturally thought that as "kinds" were specified in the first clause of the class the remainder were to be distinct kinds also; and in all likelihood, if they had felt free to make up with varieties, their collections, good as they were, would have been stronger. We understand that Mr. McIndoe had a doubt on the point, but the canny man wrote to the authorities and received their sanction to show duplicates (distinct varieties) of some of the kinds of fruit, and so fortified himself against a possible protest. He won well on the merits of the fruit and its arrangement. Mr. J. H. Goodacre, Elvaston Castle Gardens, was second with a good all-round collection, and Mr. H. W. Ward, Longford Castle Gardens, a very close third. The former of these two exhibitors had as his best dishes capital *Muscat* and *Black Hamburgh Grapes*, *Pines*, *Peaches*, *Nectarines*, and *Cherries*; and the latter fine *Gros Maroc* and good *Madresfield Court Grapes*, handsome *Peaches* and *Nectarines*, and good *Pines*.

Class 2: "Collection of twelve dishes of fruit. Black and white

Grapes, two bunches of each, and two Melons required; one dish only of any other kind." This is precise. Six collections were staged, Mr. R. Parker, Impney Gardens, winning the first prize, £8, with excellent, well-finished, and admirably staged fruit—namely, fine Muscats and good Alicante Grapes, one of the best Pines in the Show (Smooth Cayenne), two large Melons, Best of All and an unnamed seedling, Princess of Wales Peaches, Elruge Nectarines, Kirke's Plums, Morello Cherries, Large Early Apricots, Worcester Pearmain Apples, and Jargonelle Pears, all of excellent quality. Mr. G. Reynolds, Gunnersbury Park Gardens, was a remarkably good second, his best dishes consisting of Gros Maroc and Alicante Grapes, Melons, Pine and Victoria Nectarines, all very good; and a splendid dish of Clapp's Favourite Pear. Mr. T. Coomber, The Hendre Gardens, Monmouth, was third, his best dishes being splendid Gros Maroc and good Muscat Grapes, good Melons, Kirke's Plums and Figs, with a large crowned Pine. Mr. Goodacre was a close third with a capital, even, all-round collection.

Class 3: "Collection of fruit to consist of eight distinct dishes (white and black Grapes to be considered distinct), Pines excluded." Distinct kinds are implied, but not stated here, and if kinds were meant the following terms would have been much more definite—"Collection of eight dishes of fruit, distinct kinds," &c. There were eleven competitors in this class, Mr. J. McIndoe being well in advance with good and well finished examples of Duke of Buccleuch and Black Hamburgh Grapes, Golden Eagle Peaches, Humboldt Nectarines, Early Transparent Gage Plums, Brown Turkey Figs, Lady Sudeley Apples, and a Melon. Mr. J. Dumble, gardener to Sir C. Phillips, Bart., Haverfordwest, was second with Peaches, Nectarines, Figs, Plums, Pears, and a Melon, in addition to good Muscat and Black Hamburgh Grapes. Mr. J. Dawes, gardener to M. Biddulph, Esq., Ledbury Park, was third, staging very fine Gros Maroc Grapes, Barrington Peaches, Humboldt Nectarines, and Roman Apricots. Mr. A. Ocock, gardener to Mrs. McIntosh, Havering Park, Romford, was fourth, his best dishes being Figs and Peaches. The exhibits in the above three classes made a good show in themselves.

GRAPES.—Of these the display was extensive, and many splendid bunches were staged, though several were not well finished. Four collections of ten varieties, two bunches of each, were placed in competition, the first prize of £8 being won by Mr. McIndoe with a heavy exhibit. First to be named was a seedling with large, well-shouldered bunches of the character of Gros Guillaume, and berries as large and as black as Gros Colman; parentage Gros Guillaume and Duke of Buccleuch. It is desirable that the quality and keeping properties of this fine-looking Grape be tested and made known. The remaining varieties in the collection were Gros Colman and Duke of Buccleuch, medium bunches, large clear berries; Alicante, well finished; Gros Guillaume, heavy and good; Trebbiano, large, not finished; Black Hamburgh, good bunches, rather small berries; Gros Maroc and Golden Champion, very fine; and good examples of Lady Downe's. Mr. G. Reynolds was an excellent second with good, medium-sized, even bunches and fine, well-finished berries, the varieties best represented being Alicante, Gros Maroc, Mrs. Pearson, and Madresfield Court. Mr. Goodacre was third, and Mr. Ward fourth.

Six collections of five varieties, two bunches of each, were staged, the contest for supremacy resting with Mr. W. Allan, Gunton Park, and Mr. W. Elphinstone, Shipley Hall. The former won with Alnwick Seedling, Gros Maroc, and Madresfield Court, very fine; and good examples of Black Hamburgh and Buckland Sweetwater. Mr. Elphinstone's bunches were generally heavier, Muscats, Gros Maroc, and Black Hamburghs being exceptionally good. A very close second. Mr. J. Bury, gardener to C. Bayer, Esq., Forest Hill, was third, his Madresfield Court being particularly clean and good. Mr. T. Osman, gardener to L. L. Baker, Esq., Chertsey, was fourth with heavier bunches but not so well finished.

Fourteen competitors staged three bunches each in the Black Hamburgh class, but several of them had lost colour if they ever possessed it. Mr. J. Gibson, Draycot Gardens, Chippenham, was first with good bunches, though a trifle loose, and well coloured berries. Mr. G. Reynolds was a very close second with firmer bunches and good berries. Mr. J. McNaughten, gardener to Lord Tankerville, Kingston-on-Thames, was third with much larger and fairly coloured examples.

With three bunches of Muscat of Alexandria Mr. G. Reynolds won the premier position against nine other competitors with beautiful bunches of fine and well-finished berries; Mr. J. Dumble second with much larger specimens, the berries smaller yet good; and Mr. Elphinstone a remarkably close third, with really good examples not quite finished, but very nearly so. This was the best class of Muscats of the year; it was a great honour to win a place in it, and no disgrace to lose. In violent contrast was the class for Gros Colman, in which there was only one exhibitor (Mr. McIndoe), his bunches meriting the first prize that was awarded.

Mr. J. Gibson was first with three bunches of Madresfield Court, admirable in size, shape, berry, and finish. Mr. G. Elliott, gardener to P. Graham, Esq., West Moulsey, was second with large bunches, not improved by a jutting shoulder on each. Mr. Berry was third with medium-sized bunches and well-finished berries. Seven competitors, and a good class.

The Black Alicante class was also good, six exhibitors staging well. Mr. S. T. Wright, gardener to C. Lec Campbell, Esq., Glewston Court, Ross, outdistanced all rivals with full heavy bunches and fine berries. Mr. J. Hollingworth, gardener to C. M. Campbell, Esq., Woodseat, Uttoxeter, was second with good bunches; and Messrs. T. Rivers & Son third with medium bunches but better finished berries.

In the class for three bunches of any white Grape except Muscat of Alexandria there was an imposing display by nine exhibitors. Mr. Peter E. Kay, Finchley, was placed first with long full bunches and good berries of Canon Hall Muscat. Mr. Elphinstone was a close second with still finer berries, and large but less compact bunches. Mr. J. Vert, The Gardens, Audley End, Saffron Walden, third with good examples of Trebbiano.

With three superb bunches of Gros Maroc Mr. G. Reynolds won the first prize in the class for any other black Grape than those above specified. Mr. T. Coomber was second, and Mr. W. Iggulden, Marston Gardens, third, with good examples of the same variety. This was a very fine class of fifteen competitors.

Prizes were offered for baskets containing 12 lbs. of Grapes, packed for transit by rail, and delivered at a distance of not less than twelve miles; also for boxes containing 10 lbs. of Grapes, packed for transit by rail or parcels post, delivered at a distance of not less than ten miles. Several baskets were disqualified through not being in strict conformity with the terms of the schedule, which were not, however, so explicit as they might have been. Mr. J. Hudson, Gunnersbury House Gardens, Acton, was first in the basket class, Mr. Sutton, gardener to Earl Stanhope, Sevenoaks, second, and Messrs. T. Rivers & Son third. The two last-named exhibitors had their bunches tied round the sides of cross handled baskets. Mr. Hudson's were not tied, but kept immovable by drawing the tissue paper lining from the sides of the basket and packing the space behind the paper with moss. The only well packed box of Grapes was sent by Mr. J. Turton, gardener to F. Hargreaves, Esq., Reading, who was awarded the first prize.

FIGS.—These were fairly good. Mr. J. Evans, Melchet Court, Romsey, was first for one dish, showing fine samples of Brunswick. Mr. H. W. Ward was second, the third prize going to Mr. J. Batten, gardener to J. A. Venables, Esq., Wimbledon Park. There were twelve competitors. Mr. J. Wallis, gardener to Ralph Sneyd, Esq., was the only competitor with three dishes, and secured the first prize. The varieties shown were Osborne's Prolific, White Ischia, and Brown Turkey.

PEACHES AND NECTARINES.—Mr. R. Potter, gardener to Sir M. W. Callet, Bart., Sevenoaks, had the best three dishes of Peaches, showing well grown samples of Grosse Mignonne, Dr. Hogg, and Crimson Galande. Mr. W. Carr, Croydon, was a close second, and Mr. H. W. Ward third. Mr. J. Austen, Stourport, had the best single dish of Peaches, showing fine fruits of Hale's Early. Mr. R. Potter was second with a fine dish of Crimson Galande; Mr. G. Helman, gardener to Lord George Lewis, being third. For two dishes of Peaches Mr. J. Dawes, gardener to M. Biddulph, Esq., was first with A Bec and Violette Hâtive; Mr. Haines, Highworth, second, and Mr. Miller third. Nectarines were fine and well coloured. For three dishes, distinct varieties, Mr. R. Potter was first with Spenser, Rivers' Orange, and Elruge. Mr. W. Carr, Croydon, was second; the other principal exhibitor being Mr. H. W. Ward, but no prize card was on the exhibit. For two dishes of Nectarines Mr. Dawes secured first honours with well coloured examples of Lord Napier and Humboldt. Mr. J. Miller, Ruxley Lodge, was second. Mr. Dawes was also first for one dish, showing Lord Napier; Mr. Turton second, and Mr. Mundell third.

PLUMS.—For three dishes of red Plums Mr. McIndoe was first with Pond's Seedling, Victoria (Denyer's), and Sultan. Messrs. T. F. Rivers and Son were second, the third award going to Mr. A. W. Porteous. Mr. W. Lane was first for three dishes of purple Plums, showing Black Diamond, Prince Engelbert, and Kirke's. Mr. Iggulden was second, and Mr. McIndoe third. Mr. Iggulden was first for three dishes of green or yellow varieties, showing Golden Drop, Early Transparent Gage, and Washington. Mr. McIndoe was placed second, and Mr. H. W. Ward third. There were ten competitors in this class. For one dish of dessert Plums Mr. J. Vert, gardener to Lord Braybrooke, Saffron Walden, was first with Jefferson. Mr. Hudson, Gunnersbury, was second with Kirke's, and Mr. G. Reynolds was third. For one dish of culinary Plums Mr. H. W. Ward was placed first for fine examples of Diamond, Mr. T. Turton second, and Mr. McIndoe third.

PINE APPLES.—These were exceedingly good. Mr. C. Slade, gardener to the Duke of Newcastle, Worksop, was first for three fruits, showing Smooth Cayenne well grown. Mr. Slade also exhibited a "not for competition" collection of Pines, and was awarded a silver-gilt medal. Mr. T. Coomber was second, and Mr. J. Toy, Pinner, third. There were five competitors. Mr. A. Methven, Wimbledon Park, was first for a single Pine, showing a well-grown Smooth Cayenne.

APPLES AND PEARS.—In the class for six dishes of cooking Apples, distinct, the competition was very keen. There were ten competitors. Mr. Thos. Turton, gardener to J. Hargreaves, Esq., Reading, was first with nine very fine dishes of Lord Suffield, Waltham Abbey Seedling, Warner's King, Peasgood's Nonesuch, The Queen, and Ecklinville Seedling. Mr. McKenzic, gardener to J. Cornwallis West, Esq., Maidstone, was second, and Mr. G. Reynolds, Acton, third. With three dishes there were twelve competitors, the first prize being awarded to Mr. Will Tayler, Hampton, for Warner's King, Lord Suffield, and The Queen. Mr. A. W. Porteous, Chiswick, was second, and Mr. J. Thompson, Homerton, third. There were twenty entries in the class for a single dish of Apples, and the competition was very keen. Mr. T. Turton secured first honours with a remarkably fine dish of Peasgood's Nonesuch. Mr. McKenzic was second, and Mr. Taylor third. For three dishes of dessert Apples, Mr. G. Goldsmith, Horsham, was first, showing Lady Sudeley, Beauty of Bath, and Red Astrachan. Mr. Reynolds was second, and Mr. T. Turton third. There were seventeen competitors. For one dish of dessert Apples there were no less than twenty-four

entries, the first prize falling to Mr. T. A. Hester, Plumstead Common, for a dish of well-coloured Red Astrachan. Mr. C. Sutton, gardener to Earl Stanhope, Sevenoaks, was second, and Mr. A. Wyatt third.

For three dishes of cooking Apples, grown under glass, Mr. T. Turton was first, Mr. McIndoe second, and Mr. J. Nicholson, gardener to J. W. Mellis, Esq., Chingford, third. For one dish of cooking Apples Messrs. T. Rivers & Son were first with Peasgood's Nonsuch, Mr. Turton second, and Mr. Nicholson third. Mr. J. McIndoe secured first prize for three dishes of dessert Apples, showing Worcester Pearmain, Jefferson's, and Gravenstein. Mr. Turton was second, and Mr. S. T. Wright, Glewston Court, third. For one dish of dessert Apples Messrs. T. Rivers and Son were first, showing very fine samples of Cox's Orange Pippin. Mr. McIndoe was second, and Mr. C. Sutton third.

For one dish of Pears, grown in the open air, Mr. R. Parker was first; Mr. J. C. Mundell, gardener to Lord Ebury, Rickmansworth, second, and Mr. G. Helman third. For three dishes Mr. R. Potter was first with Clapp's Favourite, Williams' Bon Chrétien, and Souvenir du Congrès. Mr. Helman was second, these being the only competitors. Messrs. T. Rivers & Son were first with three dishes of Pears grown under glass, showing Clapp's Favourite, Souvenir du Congrès, and Williams' Bon Chrétien; Mr. Nicholson second, and Mr. McIndoe third. Messrs. Rivers & Son were also first for one dish, showing very fine Pitmaston Duchess. Mr. G. Reynolds was second, and Mr. McIndoe third.

TOMATOES.—These were exceedingly good, and the competition keen. For three dishes, distinct, Mr. J. Roberts, Shepperton, was first with Webb's Jubilee, The Cardinal, and Early Ruby; Mr. J. Bury, Forest Hill, second; and Mr. Thompson, Hounslow, third. Mr. E. Ryder, Orpington, had the best six dishes, the varieties being Golden Sunrise, Ham Green, Stamfordian, Perfection, Ignotum, and Optimus. Mr. J. Hill, New Malden, was second, these being the only competitors. There were eighteen entries in the class for one dish of red Tomatoes. The fruits shown were very fine, and the first award went to Mr. J. Hill, after a close fight, for a grand dish of Suttons' Reading Perfection; Mr. J. Roberts was second with Webb's Jubilee; and Mr. Dawes third with Ham Green. Mr. G. Ryder secured the first prize for a dish of yellow Tomatoes, showing Golden Sunrise; Mr. J. Bury second; and Mr. J. Fry third.

Miscellaneous collections of fruit were numerous. Messrs. J. Cheal and Sons, Crawley, were awarded a silver medal for a splendid collection of Apples and Pears. Dwarf Apple trees, laden with fruit in pots, were also shown by Messrs. Cheal & Sons. Messrs. G. Bunyard & Co., Maidstone, also had a grand collection of fruit, highly coloured, for which a silver medal was awarded. Golden Spire, Potts' Seedling, Grenadier, and Lady Sudeley were very fine among the Apples in this contribution. Messrs. T. Rivers & Son likewise staged a remarkably fine collection of Apples, Plums, Pears, and Peaches in pots, the trees being covered with fruit, and were awarded a gold medal. Messrs. Lane & Sons received a similar award for a collection of orchard fruit and Vines in pots, the latter being very fine. Messrs. W. N. White & Co., Covent Garden, were awarded a silver-gilt medal for a large collection of English and foreign fruit. Messrs. W. Paul & Son, Waltham Cross, showed a number of Peaches and Nectarines in pots, the trees being laden with fruit. Messrs. Jarman & Co., Chard, had an extensive display of fruit and vegetables, for which they received a silver medal. Messrs. Butt and Son, High Street, Kensington, had a wonderful collection of market fruit, occupying 100 square feet of tabling, obtained from Mr. Munro, Covent Garden, Grapes, Plums, Figs, Melons, Peaches, and Nectarines, also Mushrooms, Cucumbers, and Tomatoes, were in splendid condition. A gold medal was awarded. Mr. J. Walker had twenty-four dishes of Apples, magnificent fruit of Grenadier, Lord Grosvenor, Peasgood's Nonsuch, Lane's Prince Albert, Peter the Great, Stirling Castle, New Hawthornden, Duchess of Oldenburg, Lady Sudeley, Damien, Bismarck, Cox's Orange, and Quarrenden. Mr. Rickwood, Twickenham, received a bronze medal for a collection of Peaches.

MISCELLANEOUS.

The miscellaneous exhibits were numerous and varied. Messrs. E. D. Shuttleworth & Co., Peckham Rye, staged a remarkably fine group of Palms, Crotons, Ferns, Lilioms, and other plants, the whole making an imposing display. A gold medal was awarded. A small group of blue and white *Campanula pyramidalis*, showed by Mr. G. Wythes, Syon House Gardens, Brentford, and arranged with Palms and Ferns, was most effective (silver-gilt medal). Near by a collection of Crotons (silver-gilt medal) from Mr. F. McLeod, Dover House, Roehampton, attracted some attention. These were small plants, but most highly coloured, *C. Thompsoni* being particularly showy. We have seldom seen better coloured Crotons than these. Messrs. H. Cannell & Sons staged a splendid collection of Cactus and Pompon Dahlias, the flowers being fresh and bright. Ernest Cannell, Glory of Swanley, and Mrs. Rolfe were especially attractive in this group; a silver-gilt medal was awarded. Mr. C. Turner, Slough, also had a number of boxes of Dahlias effectively set up in bunches with their own foliage. This method might with advantage be more generally followed. Helianthus arranged similarly were very effective, and the Roses shown by Mr. Turner were likewise fresh and bright (silver-gilt medal).

Tuberous Begonias were well represented. Messrs. J. Laing and Sons, Forest Hill, S.E., staged a magnificent group of single and double varieties (gold medal). Possibly this was one of the finest groups of Begonias ever arranged. The flowers were remarkably fine, especially the double varieties. Among others Stanstead Gem, Duke of York, Duchess of Teck (a fine yellow), and Lady Esher (a splendid white)

were conspicuous. The plants were arranged in an undulating bank, the surface being broken by Palms and *Asparagus plumosus*. The group was edged with Maidenhair Fern, *Isolepis gracilis*, and small plants of *Caladium argyrites*. Messrs. Laing & Sons are to be congratulated on this magnificent display. On each side a small group of Palms and Ferns added to the effect. Messrs. Kelway & Sons, Langport, had a collection of Gladioli, Gaillardias, and hardy flowers (silver-gilt medal). Messrs. J. Veitch & Sons, Royal Exotic Nursery, Chelsea, staged branches of hardy shrubs and trees (silver-gilt medal), amongst which were *Cornus alba* Spathi, *Cytisus capitatus*, and several Oaks, including *Quercus macrophyllus* (very fine foliage), and *G. pedunculata* Concordia (a yellow-leaved variety) were noticeable. Boxes of hybrid *Streptocarpus* and *Rhododendron* blooms were also shown by Messrs. Veitch & Sons. A group of Crotons from Messrs. B. S. Williams & Son, Upper Holloway, was also effective and a gold medal was awarded, whilst Mr. W. Marshall, Bexley, secured a similar honour for a collection of Ferns. Messrs. W. Paul & Son, Waltham Cross, staged a fine collection of Roses, bright, fresh and clean in appearance. A box of *Maréchal Niel* was particularly good for the season. Dahlias, Helianthus, Asters and other flowers were likewise shown by Messrs. W. Paul & Son, the whole being most effective and securing a gold medal. Three boxes of early flowering *Chrysanthemums* set up in bunches were shown by Mr. W. Beech, gardener to L. Seligman, Esq., South Kensington. Messrs. W. Cutbush and Sons, Highgate, and Messrs. Laing & Sons were awarded medals for collections of hardy flowers (the former receiving a silver and the latter a silver-gilt). Cape Pelargoniums and the plant of *Asparagus deflexus* mentioned in our last issue were shown by Mr. Hudson, Gunnersbury Park Gardens, and a silver-gilt medal was awarded. Mr. A. Rawlings Romford, had a stand of Dahlias and Helianthus, securing a similar honour. Orchids were finely shown by Messrs. F. Sander & Co., St. Albans, and a gold medal was awarded. Several species and varieties were also adjudged certificates. A number of new and rare plants shown by Messrs. B. S. Williams & Son were similarly honoured. Mr. J. R. Chard received a silver medal for his beautiful table decorations, Messrs. Herb and Wutte for a collection of cones, and bronze medals went to Messrs. Beech and McMillan for *Chrysanthemums*, Webb and Brand for Hollyhocks, and Gibson for Onions.

Apart from the splendid show of fruit and flowers above reported it may be of interest to mention that the landscape garden at the International Horticultural Exhibition is exceedingly beautiful just at present. This, as has been previously stated, is under cover, and early in the season some difficulty in getting the grass to grow was experienced. At present, however, the turf is as green as it possibly can be under the circumstances, affording ample proof that no small amount of trouble has been expended on it. The beds, too, are filled with beautiful flowering and foliage plants, those planted by Messrs. B. S. Williams & Son, J. Laing & Sons, G. Phippen, and other nurserymen being most effective. This noticeable feature of the Exhibition is alone well worth seeing, and country gardeners might with advantage pay it a visit.

THE DINNER.

Except on special occasions gardeners do not often meet in the manner in which they did at Earl's Court on Friday evening last. It was a typical gardeners' social gathering, and everyone seemed to enjoy the excellent repast provided. About 200 sat down to the dinner, and Mr. W. Thomson of Clovenfords occupied the chair. Amongst others present were Major Mackenzie (Superintendent of Epping Forest), the Rev. W. Wilks (Secretary of the Royal Horticultural Society), Mr. Ingram (Secretary of the Gardeners' Royal Benevolent Institution), Messrs. J. Laing, F. W. Burbidge, F. Moore (Dublin), Owen Thomas (the Queen's gardener), A. F. Barron, W. Marshall, A. Dean, R. Dean, J. Hudson, and many other well known gardeners and nurserymen.

After the customary loyal toasts had been drunk, the Chairman proposed—"Success to Gardeners and Gardening." On rising Mr. W. Thomson was received with much enthusiasm, and he made an eloquent and practical speech. He took a retrospective view of gardening, and said that while vast improvements in the craft had been made during the past half century, gardeners should not forget that there were successful cultivators in bygone days, and men with whom he had been acquainted. In Scotland they had had men who could grow Heaths such as were now rarely seen, while vegetables and fruit were equally well done. Many names he mentioned of successful cultivators who had passed away, but who were still fresh in their minds. Gardening, too, in the days to which he referred was carried on under greater difficulties, he said, than at the present time.

Regarding the wages question, Mr. Thomson spoke strongly and to the point. He hinted that there were gardeners and gardeners; some worthy of the name, others little more than garden labourers. There were men to be had for £70 or £80 a year, but cheap gardeners were dear in the end. He never lost an opportunity of urging employers to pay a fair salary and secure an efficient gardener; £100 per year would secure a good man. Gardeners, he said, taken as a whole, belonged to a superior class of society, and yet no men were so badly remunerated. They had a great responsibility resting on their shoulders, and so to speak, were always on duty. Why, therefore, should they not be better paid and better treated than they generally are? (Applause.)

The Rev. W. Wilks, in responding, remarked that he fully sympathised with what Mr. Thomson had said as to the remuneration of gardeners. Considering the abilities of gardeners generally he thought

they were the worst paid class of men in the land (hear.) For a long time he had been trying to impress upon gentlemen the fact that they should pay their gardeners higher wages.

Mr. W. Marshall proposed "Gardening Charities," mentioning the Gardeners' Orphan Fund, the Gardeners' Royal Benevolent Institution, and the United Horticultural Benefit and Provident Society. Messrs. A. F. Barron, G. Ingram, and J. Hudson responded on behalf of the respective Societies. Mr. Ingram, on behalf of Mr. H. J. Veitch and Mrs. Veitch, took the opportunity to thank the gardeners for the presents they had given the latter on occasion of their silver wedding.

Major Mackenzie gave "The Chairman," and reminded those present that not only was Mr. Thomson a veteran successful horticulturist, but that many of the best and largest gardens in this or other countries were under the management of men who had been pupils of Mr. Thomson. A brief response by the Chairman brought the proceedings to a close.

KINGSWOOD.

THIS promises to soon become one of the best Shows and most popular fixtures in the neighbourhood of Bristol. In the open classes the prizes are good enough to attract some of the leading plant growers in the country, while the local private gardeners, amateurs, and cottagers all show remarkably well. With twelve flowering plants Mr. J. Cypher, Cheltenham, was well first, these consisting of *Erica Austiniana*, *E. Marnockiana*, *E. Turnbulli*, *Allamanda grandiflora*, *A. nobilis*, *Anthurium Schertzerianum*, *Clerodendron Balfourianum*, *Ixora Pilgrimi*, *I. Fraseri*, *I. Williamsi*, *Erica Eweriana*, and *E. Thompsoni*. Mr. J. F. Mould was awarded the second prize. Mr. G. Tucker, gardener to Major Clarke, Trowbridge, was a very close third. Mr. Cypher was also first for eight fine-foliaged plants, having beautifully coloured *Crotons* and well-grown *Palms*. With six *Fuchsias* Mr. G. Harris, gardener to the Clifton Zoological Society, was first, Mr. T. Fussell being a good second. The best six Zonal *Pelargoniums* were shown by Mr. G. Tucker, the second prize going to Mr. W. Smith. The last named was easily first for six double-flowering varieties, Mr. S. Bryant, gardener to Dr. Grace, being second. Exotic Ferns were well shown. Mr. Tucker was placed first for eight varieties. Mr. W. Rye, gardener to Captain Bellfield, was a very close second.

In the classes confined to private gardeners and amateurs Mr. W. Rye was the most successful, but several other gardeners exhibited in a very creditable manner. The first prize flowering plants were staged by Mr. Rye, and all were in good condition; Mrs. Coles being second. Similar positions were occupied by these exhibitors in the class for six fine-foliage plants, Mr. Rye staging fine specimens. The best six exotic Ferns were also staged by Mr. Rye, all being large and healthy. Mr. J. W. Langdon was a good second. Tuberous *Begonias*, Zonal *Pelargoniums*, *Cockscombs*, and other plants were all well shown by various growers, the competition generally being close and good.

Cut flowers were a great feature of the Exhibition, the Bath growers being particularly well represented. For twenty-four triplets of *Roses* Dr. Budd, Bath, was a good first, and Messrs. Parker & Sons, Bristol, second. *Dahlies* were numerous and good. With twenty-four varieties and twelve *Fancies* Mr. G. Humphries, Chippenham, was first, being closely followed in both instances by Mr. T. Hobbs, Bristol. The best stand of single *Dahlias* came from Mr. A. A. Walters, Bath, Mr. Humphries being a good second. The last named won with *Cactus* varieties, Mr. F. Williams being second in this instance. *Asters* made a grand display, the best twenty-four French varieties being staged by Mr. G. Galloway, Bath, other Bath growers also showing well. *Gladioli* in twenty-four distinct varieties were more numerous than usual, the quality also being good. Mr. A. A. Walters was first, and Mr. W. Smith a close second, crowding the spikes in the latter instance greatly detracting from their appearance. The best twelve bunches of stove and greenhouse flowers were shown by Mr. Shelton, gardener to W. R. Wait, Esq., Bristol, Mr. G. Tucker following closely. *Begonias*, both single and double, were above the average, the classes also being better filled than at most exhibitions. The most successful with these were Messrs. T. M. Mobsby, gardener to Alderman F. F. Fox, and the Rev. G. H. Jackson. Hardy flowers in twelve varieties made a grand display. Mr. A. A. Walters was first, and Mr. G. Garraway second. Very good also were the *Hollyhocks* as shown by Mr. T. Hobbs and Mr. W. Smith.

There is considerable room for improvement in the fruit classes, though some of the single dishes shown were very good. The first prize in the open class for a collection went to Mr. E. Hall, Bath, and in the local class Mr. W. G. Coles was first, and Mr. P. Fussell second. Mr. S. Bryant had a first prize for grandly set and well-finished bunches of *Muscat Hamburgh*, and also for good *Foster's Seedling Grapes*; Mr. J. Marshall, gardener to Mrs. Doel, also being successful with *Grapes*. The best *Melon* was shown by Mr. Coombs, gardener to J. W. Langdon, Esq., Mr. E. W. Towill being second. With *Peaches* Mr. W. Rye was first, having *Crimson Galande* good; Mr. E. W. Towill was second, the last-named being first for *Nectarines* and Mr. Coombs second. *Plums*, *Apples*, *Pears*, and other hardy fruits were well shown, as also were collections of vegetables, the principal prizes for the latter going to Bath.

TRADE CATALOGUES RECEIVED.

Messrs. Fotheringham & Co., Dumfries.—*Bulbs and Roses*.
Messrs. Hogg & Wood, Coldstream and Duns, N.B.—*Bulbs*.

HARDY FRUIT GARDEN.

Gathering and Storing Fruit.—This is work requiring more or less daily attention from now onwards to the close of the fruit season. On its careful performance depend in a great measure the quality and keeping capabilities of even the best and most perfect samples of fruit. Good culture brings fruit to perfection in a natural manner sooner or later, but when this is attained means must be taken to insure its preservation either for long or short periods in the best possible manner. The first essential to success in securing perfect samples in every respect is to gather the individual fruits at exactly the right time. This can only be known by carefully watching the ripening process as it goes on at or near the period when each particular variety is known to be fit for use. In different localities the same varieties vary considerably in their time of ripening, as also they do in the same districts according as they are influenced by soil, position, and culture. The usual test, and one that is generally reliable for ascertaining the fitness or otherwise of fruit to be gathered, is to carefully raise up each fruit, when, if the ripening process has been almost completed, the fruit will separate itself readily from the spurs; but if the connection between the wood and the fruit is still strong, so as to render separation difficult without twisting and injuring the stalk, then the time for gathering has not come. Every fruit should receive as little and as careful handling as possible, laying each as gathered separately in flat baskets, taking care not to bruise or damage in the slightest degree the skins and the flesh immediately underneath. The nearer the fruits are to maturity the more care is required. Most fruits, *Pears* especially, are best gathered just before ripening is completed. When allowed to stay too long *Pears* develop a musty flavour; if gathered too soon the peculiar aroma of the variety is not secured, a watery taste being developed instead. *Plums* staying too long on the trees are apt to crack, and *Apples*, too, fall of themselves, becoming injured and useless for storing. Sometimes maggot affects the *Apple*, many fruits being spoiled by their boring and the premature ripening they induce. Gather all such fruits as soon as possible after they fall to prevent the depredations of the larvæ another year. All good fruits when gathered should be laid thinly in dry cool quarters, where they will develop their own peculiar aroma and flavour.

Protecting Fruit.—Wet weather affects all ripening fruit more or less, and if it is likely to be long continuous protection must be afforded to soft fruits such as *Currants*, *Plums*, and *Cherries*, which are often preserved on the trees as long as possible to afford a late supply. Any special fruits intended for exhibition ought to have the early protection of gauze bags, which effectually prevents all winged insects from attacking them. Large quantities of fruit may be enclosed with hexagon netting, which will baffle wasps and bluebottle flies, these also being caught by a sweet mixture of treacle and beer contained in bottles suspended among the branches of any trees they are likely to attack.

Perfecting Fruit and Wood.—The effects of good culture are always apparent in bringing fruit nearer to its proper season of maturity, improving its quality, and ensuring an excellent finish. It is noticeable that *Jargonelle Pears* produced on trees that have not been properly cultivated—that is, neglected in many important respects—are never so large, fine, and early as on trees better managed. The reason is that support, which should be directed to the fruit, is attracted powerfully in other directions, often to useless parts, and the development of the fruit is retarded or proceeds very slowly. Sometimes fruit cannot develop through lack of support by the roots. The remedy for this is the application of stimulants in the form of liquid and artificial manures. Assistance of this kind, however, must be applied judiciously, or the result may be the forcing of too strong wood growth, where that may be already plentiful and vigorous enough. Manurial assistance is best given during the period when the fruit is hard and green, its enlargement then needing acceleration and help the most. Moisture at other times during growth must be afforded, if not of a stimulative character, to assist the double strain of fruit-perfecting and fruit-bud-forming processes. The month of September is the period in which trees are employed in ripening the wood made during the current season. Any diminution of nutrition or moisture then occurring produces less plump fruit buds and stronger wood buds, also in some cases invites, especially during a very dry period, fresh attacks of red spider on the foliage, which arrests the important work the leaves perform, inducing premature wood ripening. When the roots of fruit trees are mainly produced near the surface of the soil feeding induces them to stay there, thus maintaining a proper balance of health, fertility, and vigour.

Peaches, Nectarines, Apricots.—The shoots which have borne the current year's crops having been relieved of fruit ought to be cut back to the point from which the succession shoots start, these being securely fastened to the wall to induce speedy ripening of the wood. This, perfect cleanliness of the foliage, and just sufficient moisture at the roots to maintain health and vigour without encouraging second growth, are the main points to be aimed at.

Outdoor Vines.—Regulate the laterals, and see that no overcrowding takes place. Where good crops of fruit are hanging little lateral growth will have been made lately, and what there is will, with some of the principal leaves, be required to shade the bunches of black Grapes, the white varieties enduring, as well as needing, more sun to ripen perfectly. Any bunches attacked by wasps or flies should be enclosed in gauze bags.

Plums and Cherries.—Secure the current shoots of Plums and Cherries to walls. Shoots which have been summer pinched to form spurs will probably be producing sub-laterals. These will require pinching or cutting back to one leaf. Any further growths produced afterwards rub out altogether. See that the current year's shoots of Morello Cherries are not left too thickly placed. Now, while the foliage is on, is the best time to see whether the shoots are crowded or otherwise. Any dead or dying branches remove at once, using a sharp saw, and making a clean smooth cut.

FRUIT FORCING.

Vines.—*Early Forcing in Pots.*—Vines for starting in November to supply Grapes fit for table next March or April must not be allowed to become dust-dry at the roots, for that impairs their vitality and causes the buds and growths to be weak. Sometimes the shoots are blind—the incipient bunches collapsing instead of developing—through the Vines having been kept too dry during the latter part of their growth to insure the ripening of the wood. The Vines should now be at rest, the wood quite ripe, the buds plumped, the laterals cut close home, and the canes shortened to about 6 feet, more or less, according to the situation of the buds. Dress the cuts whilst they are dry with the best French polish, or patent knotting, as a preventive of bleeding. They should be kept in a cool, airy house. If the Vines have to be bought they should be ordered now, so as to secure sturdy well matured canes, with plump buds, of the desired varieties. The most suitable varieties for very early forcing are White Frontignan, Foster's Seedling, Black Hamburg, and Madresfield Court.

Earliest Forced Planted-out Vines.—To afford ripe Grapes in May the Vines should be started early in December, and they must be pruned and given a few weeks' rest before exciting them into growth. It is not necessary to wait until all the leaves are down before pruning Vines with thoroughly matured wood for early forcing, but the wood must be brown and hard, and the leaves turning yellow. If the Vines are in good condition they will afford useful bunches when pruned to a couple of buds from the base, but closely pruned Vines do not always produce bunches that are sufficiently taking in appearance for home use or market, and in that case the spur shoots may be left a little longer—say pruned to three or four buds, with a view to larger bunches. When this method is adopted (and it becomes necessary when the Vines are weak through heavy cropping or a long course of forcing) shoots should be encouraged from as near the base as possible when the Vines start into growth, and these should not be allowed to carry fruit, but be stopped at about the sixth leaf, the laterals at the first leaf, and the sub-laterals to one leaf as produced. The extra foliage will invigorate the Vines by the increased root action, and they will store more food, because they will lay on new and larger layers of wood, through which the sap will flow freely, and the Vines derive increased benefit accordingly for future crops. Moreover, the current crop will receive more support in consequence of the extra foliage, and such shoots are sure to form good buds, the fruiting growths being cut away in due time in favour of the other for fruiting the following season. This very old alternate system of fruiting necessitates the shoots being kept wider apart for development and exposure to light and air. Any extension should be cut back to plump buds on firm ripe wood, being guided by the space at command and the strength of the canes, always having due regard to ample space for the subsequent growths, for there must not be any overcrowding.

Weakly Vines.—Those not in a satisfactory condition may be improved by removing the soil down to the roots, picking it out from amongst them and supplying fresh loam, raising the roots where practicable and laying them in the new soil, especially those which are fibry and those proceeding from the collar. If the loam be deficient in calcareous matter add from a sixth to a tenth of old mortar rubbish, according to the nature of the soil, heavy soil needing most and light loam least. With the roots lifted, laid in fresh compost and covered 3 or 4 inches deep the Vines generally form abundance of fibres in the new material and become almost independent of the deeper roots, which are comparatively inactive through the lower part of the border having become effete. This is best done in advance of the leaves falling, and a gentle watering being given the roots will take to the new soil at once. It is a great mistake to allow Vines when at rest to become very dry at the roots, for the borders crack and part from the walls, causing the young roots to perish, and the soil is difficult to make thoroughly moist after it gets into a parched condition. The outside borders should have a covering of some kind to protect the roots from the heavy autumn rains, which reduce the temperature considerably. Glass lights are best so raised as to throw off rain and admit of a free circulation of air. The sun heat warms the soil, and a covering of leaves, with a little litter on them to prevent their blowing about, conserves the heat. It is necessary, however, to secure the thorough moistening of the soil before the Vines are started; therefore some growers expose the borders to the October rains, and merely cover them with leaves before cold weather sets in.

Late Houses.—Grapes have had a grand time of late, thunderstorms

to moisten outside borders, and a genial atmosphere, with abundance of light and heat. That is what Grapes want in the late stages of swelling, and because they often do not get those conditions inside the house the roots of the Vines are usually more abundant, and often of greater service in outside borders than those under glass. These must not lack water, for the Grapes swell considerably when ripening, and unless they finish plump they can hardly be expected to keep sound; indeed Muscat of Alexandria and late Grapes are a long time in ripening, and require abundant supplies of water at that period. They ought not to become dry at the roots even when the fruit is ripe. Those Grapes well advanced in ripening may have the atmospheric moisture reduced by freer ventilation, admitting a little air constantly, increasing it early on fine days, and by judicious early reduction of the ventilation the most can be made of sun heat. This is, after all, the best agent in the perfecting of Grapes, and moderate atmospheric moisture will not injure, but benefit the Vines, and assist the fruit in swelling. Whatever watering is necessary should be given in the early part of a fine day, and with air the superfluous moisture will soon be dissipated, the moisture produced having no deleterious effects provided the atmosphere is kept in motion by ventilation, and, if need be, a gentle warmth in the pipes. A day temperature of 70° to 75° is necessary by artificial means, falling 5° to 10° at night, but turning on the heat early in the morning so as to aid the sun heat, and with alternating cloud and sunshine secure a day temperature of 80° to 85°, with 10° to 15° advance on clear days. Keep the laterals well stopped and thinned, thereby admitting as much light as possible to Muscats and white Grapes generally, but black Grapes are better with a good even spread of foliage, yet without crowding the leaves, and there must not be large reductions of foliage at a time, as that might accelerate shanking, whilst frequent pinchings will not produce any appreciable check, but concentrate the forces on the perfection of the crop.

Young Vines.—Those which have made strong growth and are to be cut down to three plump buds from the bottom of the trellis to furnish a leader and side shoots, one on each side of the rod, another season, and to be grown in that way so as to produce their first crop in the third season, may be allowed to grow as long as they like, taking the precaution to keep the principal leaves that correspond to the pruning buds free of spray, so that that part of the cane may get thoroughly ripened. Vines, however, which are intended to do something more than "prove the variety" next year should have further growth discouraged by the removal of the laterals as they appear, taking care to leave some growth as an outlet for any excess of sap, otherwise the pruning buds may be started, and next year's prospects jeopardised. By this time the wood will be getting brown and hard, and the laterals may be gradually removed, cutting them back in the first instance to one joint, and in the course of twelve to fourteen days they may be cut away close to the cane, provided they have not pushed fresh growth; but if they start the buds on the laterals the growths must be pinched at the first leaf, and the removal of the laterals deferred to a later period. In this case the Vines should be assisted with fire heat, maintaining a minimum of 65° and a maximum of 75° until the wood is ripe, accompanied with free top and front ventilation.

THE FLOWER GARDEN.

Zonal Pelargoniums.—These are now growing very strongly, more so than at any time previously this season. If left to themselves they soon become crowded and weakly, whereas if kept judiciously thinned out the growth is both sturdy and floriferous. This also gives a good opportunity for putting in the requisite number of early cuttings, which will be found to pass through the winter more surely than late struck plants. If well established Zonal Pelargoniums, including the ever popular Henry Jacoby, can be kept well in boxes; but the bronze, golden and silver variegated varieties ought not to be trusted in them. All the latter, as well as late cuttings of the ordinary varieties, winter best in pots, the pots also being very convenient for storing on dry shelves and stagings. Six-inch pots, each holding about seven cuttings, answer well at this comparatively early date; but late cuttings keep better in 4-inch or slightly smaller pots, about five being placed in each. Any light sandy soil will do for the cutting pots, and if the cuttings are at all sappy trim them and let them flag for several hours in the full sunshine prior to inserting them. In any case keep them somewhat dry till they have callused, too much moisture causing them to damp off. If, therefore, the weather is dull and wet do not set the cuttings in an open sunny place, but give them the benefit of a glass covering, plenty of light and air being constantly admitted. The Ivy-leaf section, which not only bed out well but are particularly good for vases and hanging baskets, do not always strike so readily as is desirable, but if given the benefit of a moderately dry heat they will strike more freely; so also will most of the scented leaved varieties. The majority of them will strike the most readily in the spring, but if there are no large old stock plants in pots cuttings must be rooted now, as old plants do not lift well from open borders.

Tuberous Begonias.—These have not eclipsed the Zonal Pelargoniums so much as usual, the dry hot weather suiting the latter but not Begonias. These will have their turn most probably in September. Begonia cuttings treated similarly to Pelargoniums strike nearly or quite as readily. It is somewhat late to dibble them into a sunny border or at the foot of a south wall, but a number of cuttings of the best forms might well be inserted in small pots. They will strike root, form tiny tubers, and then die down, growing strongly again next spring. Late raised seedlings or any left in seed pans or boxes should not be destroyed

or interfered with. Keep them supplied with water and allow them to die down naturally in the open air. Every tuber, if no larger than Radish seed, will start into growth next spring and surpass any raised from seed in January or February. Winter them just as they are in a warm cellar or shed. Tuberous Begonias though beautiful in good mixture are still more effective when massed in separate colours. No time should be lost, therefore, in marking the various colours so as to be able to group them properly next summer.

Verbenas.—These are by no means played out, and they are yet among the best of summer bedding plants. They have grown strongly and flowered beautifully in spite of the presumably unfavourable character of the weather yet experienced. Seedlings in mixture are very attractive, but the best named varieties, in separate colours, only are tolerated where the flower beds are grouped and planted after a set plan. The great difficulty with Verbenas is in getting good soft cuttings in the spring, these only being available from healthy autumn struck stock plants. Now is the time to put in the cuttings. Select soft flowerless shoots, trim them at the third joint, and dibble them thinly either in pans or 5-inch pots, well drained and filled with a mixture of fine loam, leaf soil, and sand. Place them in a frame on a nearly exhausted hotbed, and keep them close, moist, and shaded till rooted. Winter them on shelves in a cool greenhouse.

Ageratums and Heliotropes.—Old plants of these do not lift readily. The former, it is true, can be most easily raised from seed, the strains also being good; but not so Heliotropes. If a few or many of the latter have been kept in pots to flower during the summer or autumn they will be found excellent for producing abundance of cuttings next spring. Failing these, strike cuttings of young shoots as advised in the case of Verbenas. Cuttings of Ageratums are frequently hard to obtain; but if procurable, strike them in gentle heat.

Iresines, Coleuses, and Alternantheras.—The two former seldom lift well, and besides the plants are frequently too clumsy for the purpose. Store plants in pots are ornamental enough, and produce abundance of cuttings in the spring; but if none of these exist, lose no time in rooting a number of tops, as frosts may cripple them earlier than anticipated. About six cuttings in each well-drained 5-inch pot are ample, and they ought to be kept close, shaded, and warm till well rooted. Should they give early signs of damping, enough air should be given every morning to dry the glass of the frame. Alternantheras move fairly well from the open ground, but not if they have been frosted. Few care to disturb the beds before they are obliged to do, and it is advisable, therefore, to strike a considerable number of cuttings now. Three-inch, or slightly larger pots, are the best size, five or six cuttings being placed in each. Treat as advised in the case of Iresines, and all three kinds of plants should be wintered on shelves in forcing houses or stoves.

Mesembryanthemum cordifolium variegatum.—This is somewhat difficult to manage, hence its being less often seen than formerly. Being of a succulent nature, cuttings inserted now, as advised in the case of Alternantheras, should be kept somewhat dry and in a dry heat, or they will damp off.

PLANT HOUSES.

Poinsettias.—These if brought forward under cool conditions will be sturdy plants with foliage to the base. Give more air during bright warm days; in fact, no harm will result if the lights are thrown off for a few hours during the hottest part of the day. Do not excite the plants into fresh growth by closing the frame too early in the afternoon. It will be wise to close it at night. Weak stimulants may be given occasionally, or better still, apply a little artificial manure to the surface of the soil. When the pots become filled with roots feeding must be resorted to, or the lower leaves will turn yellow and fall.

Euphorbia jacquiniæflora.—Well established plants may be given the same treatment as Poinsettias. Those in a more backward condition may be encouraged to grow, but must be fully exposed to the sun and given a free circulation of air daily. Firm sturdy growth must be made or they will fail to flower satisfactorily. Centropogons and Justicias may be grown under the conditions advised for these plants.

Crotons.—Good heads that need re-rooting should be moved at once. Side shoots that are well coloured may be taken off and rooted without delay in small pots; these will be found useful during the winter. Small plants that are well rooted may be placed into 4-inch pots and arranged on a shelf close to the glass in a warm moist structure. In this position the plants will colour freely and make capital decorative material before winter. Few plants are more effective than Crotons when well coloured for grouping during the winter months when flowers are scarce.

Gardenias.—Clean these thoroughly if infested with mealy bug by an application of petroleum and water; this should be continued at intervals until every trace has been eradicated. After syringing them with the solution a light shade should be applied until the oil has been evaporated. If plants are grown annually from cuttings they should be rooted at once. Select for this purpose young soft growths, which may be inserted in thumb pots, as every one will root in brisk heat if kept close and shaded from the sun.

Gloxinias.—Where these are appreciated, plants that flowered early and have rested may be shaken out of their pots and started again into growth. Young stock raised from seed will also flower profusely if they are placed into 4 and 5-inch pots. Do not grow them too warm, but shade them from bright sunshine.

Panicum variegatum.—Insert cuttings thickly into 3, 4, and 5-inch pots. They will root freely in a close shady place. A good stock of these plants are always useful for grouping during the autumn and winter. To have them in good condition no time should be lost in starting them, for unless well established they do not look well. A good stock of Mosses, Coleus, Fittonias, and other variegated plants should now be prepared in quantity.

Adiantum cuneatum.—If the fronds of these are to be of service when cut the plants must be grown freely exposed to the sun and given air daily; in fact, the fronds stand best when the plants are prepared in a cool house fully exposed at this season of the year. Plants that have yielded fronds for a long time, and have rested in a cool place, may be started into growth in heat. They will soon push up fresh fronds and yield a good supply for winter. Young plants in various stages of growth may be repotted if they need more root room. They will grow strongly and continue to produce capital fronds until February. Seedlings may be placed singly into thumb pots. Where seedlings are raised annually it is a good plan to place pieces of turf underneath established plants that have old fronds upon them. The spores will fall upon the turf and germinate freely. This is the easiest method of raising a stock of young plants.

Eulalias.—For grouping these are invaluable, and they are exceptionally effective in conservatories of large size. Plants that were divided in spring and have filled 6-inch pots with roots may be placed into others 2 inches larger. They increase much more rapidly when given liberal root room. When grown mainly to yield stock the plants should have a position where an intermediate temperature can be given them, as they increase much more rapidly than under cool conditions. Plants that are repotted now will continue growth until late in the year, and can be cut up into several good pieces next spring. Seed can be easily saved, but so far we have only succeeded in raising plants with green foliage. These, however, are useful, and afford variety if associated with other plants of a suitable nature.

THE BEE-KEEPER.

APIARIAN NOTES.

SUPERIORITY OF LANARKSHIRE HIVES AND PUNIC BEES.

THAT outside the pages of this *Journal* the criticism on Punic bees has been unjust and not in accordance with actual fact there cannot be the slightest doubt. Every week brings more evidence in support of my own experience. I am always of opinion when I see clergymen taking a one-sided view through party spirit that they are remiss in the more important duties they are expected to perform. I admire the articles of one when he abides by his quaint remarks, proverbs, anecdotes, and his own experience; but when he goes into deep water and meddles with matters he has evidently no knowledge of he stultifies himself. As an example: he in support of a certain editor said in effect, had he accepted the "prima facie evidence" they would have seen through the whole matter. He himself has done the opposite and accepted the secondary information on evidence. So confident am I that bee-keepers are being misled, that if anyone cares to visit our bees at the Heather (which will be cheaper than going to Africa) and finds them wanting in weight I will pay his fare to and fro; there are at least four individuals here who possess these bees. The following evidence from a reader of the *Journal*, a stranger to me, is interesting. Speaking of Punic bees he says:—"I have had the best results from one of her offspring, seventy-five sections, and the body of the hive is still too heavy. We have had a poor season here. If it were not for my big colonies I should not have been so well off for honey. Very few, if any, of the so-called standard hives have stored more than one crate of twenty-one sections. Where they have even got so much the hive will require to be liberally fed, whereas my hives are mostly too heavy. I have no extractor, not having got that length yet. I sold 100 sections on 15th July for 1s. 3d. per section, they were well sealed but not so full as I have seen them."

DRIVING AND TRANSFERRING BEES TO FRAME HIVES.

Will you please state which is the best way to drive five hives of bees from the old skeps into bar-frames, as I should like to have them all in bar-frame hives. If you could assist me in any way I should feel obliged. Could more than one be put together in the new hives?—T. T.

Invert the straw hives after you have given them a slight puff of smoke, or better still, smear a little carbolic acid upon the floor at the entrance, and push the saturated feather underneath the bees. Place an empty hive over the tenanted one, and rap on the sides of the hive of bees with two split willows or other rods, when

the bees will, after filling themselves, retreat to the empty hive. Then invert the hive containing bees beneath the frame hive, and they will run up into it, or remove three or four of the frames and shake the bees down at the open side, or draw the doorway the full length, and with a tumbler lift the bees, and shake them upon the alighting board that has a gangway with ledges from it to the ground, or shake them bodily on to the alighting board. They are not so flighty as swarms. But why not adopt one or more of hivers such as I use, and have explained repeatedly in these columns? It is one of the most useful appliances in the apiary. Two or more lots of driven bees may be shaken together without any fighting. If not gorged sprinkle both lots with very thin syrup or with pease meal, the very old Scotch fashion.—A LANARKSHIRE BEE-KEEPER.

APICULTURAL ITEMS.

MR. COWAN quotes Benton as disagreeing with the name of "Punic" bees, saying it should be "Tunisian." What will he say to Benton trying to call Carniolans "Carnic" bees in the August American *Apiculturist*? Imitation is flattery indeed. Benton, in a long article which clearly shows he has forgotten what he previously said, and has not had copies to refer to, tries to explain in the *Apiculturist* that what I said about yellow Carniolans on March 10th conveyed a wrong impression of his views. I do not admit this to be a fact, nor did I question his "views." I was answering somebody else, and not Benton at all. When a man quotes people as authorities in support of a certain position, describing them too as "intelligent," is it manly to afterwards turn round and say "Because I quoted what had been said to me by 'two intelligent bee-keepers from Upper Carniola' that I necessarily subscribe to their views?" He did not hint in the least at the time that he disagreed with them. He now says, "But I thought then, and still think, that they are a decided mark of impurity"—i.e., yellow-banded Carniolans. The italics are Benton's. If he thought so, then why did he not say so?

I do not know what Mr. Cowan will think now; he has been relying on Benton, and calling on Alley to publish Benton's after statements on the "True Colour of Carniolans." Alley has done so, and here is what Benton says of him. "He (Mr. Cowan) published my article containing my own statement that yellow-banded bees are met with in various parts of Carniola, and also my quotation of certain Carniolan bee raisers who claimed that such bees were not impure. But it seems that neither Mr. Cowan nor myself think them pure. How he explains their impurity (if he has ever attempted to do so) I do not know, nor would I attach any weight to his views in this direction, for I do not consider him any authority in this matter." Is it not cruel to be thus told he "does not consider him any authority" on such a well known race as Carniolans? How Mr. Cowan can pose as an "authority" regarding the newer race, Punics, after this is beyond my comprehension, for he admits he never saw a stock at work in this country, and says he does not know of anyone who has.

Benton makes it clear that yellow banded bees exist in Carniola, and that he and many others, "in Europe, at any rate," saw them. Mr. Cowan's statement which I questioned was, "No one, in Europe, at any rate, has ever seen or heard of pure Carniolans being yellow," and Benton further says that it "would be quite possible to produce, by constant selection, a full-banded yellow strain." Just what Alley claims to have done, and which Mr. Cowan says is impossible.

When "Old Father Langstroth," as the Americans reverently speak of him, is favourably impressed with Punics, and advises bee-keepers to give them a trial, particularly in crossing with Italians to make them more ready to work in supers, the advice of their enemies will not count for much. Langstroth is above question, whatever may be said of anyone else. He is known as the inventor of the bar-frame hive, and the pioneer in introducing foreign races of bees into America. He bred and sold home-reared Italian queens at 20 dollars each, equal to £4, with no guarantee of introduction. My price of 20s. is said to be extortionate by the same man who paid four times the price.

Mr. Benton is alleged to have said, "When you least expect it—i.e., when they have been well, and even royally treated, they will sally out and cover the manipulator with their tiny javelins." Whatever he may say now will not alter what he said in his price list issued in 1886, after his second and last journey to Tunis, as follows: "Tunisians are the blackest bees I have ever seen, are excellent honey gatherers and easy to subdue by using smoke." Since then he has never seen a "Tunisian" bee alive, so he cannot plead that he had made a mistake, which he subsequently found out. We also read, "Mr. Benton was one of the first to send out queens from Tunis." Yes, he was, and I myself got the only live queen he ever sent to Europe, no others ever landing alive until 1890 from that country.

Mr. Cowan says, "Mr. F. Benton entirely altered his views when he became better acquainted with Carniolan bees." Mr. Benton has now made it clear that he has not altered his "views," and he also makes it clear that while in Carniola, and when he left he could "view" yellow-banded bees all over the province, and his statement still stands good that he "has yet to see an apiary in Carniola where yellow-banded bees do not exist."

On page 180 "A. L. B. K." asks me to explain "how a worker bee can

become a producer of worker bees and queens." Before I begin trying to explain a natural law, first let it be established that the law exists. From what I understand no one can explain a natural law of any kind. I have told our friend how to test the matter on page 134, and when he has done so no doubt he will modify some of his views respecting laying worker bees.—A HALLAMSHIRE BEE-KEEPER.

TO CORRESPONDENTS

* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Suckers from Poplar Roots (*Ignoramus*).—The best plan would be to trench the ground and remove the suckering roots. If that is impracticable on account of other trees or objects, the suckers may be pulled up as they grow and can be taken hold of. If this is persisted in it will weaken the roots, so that they will send up suckers less freely, but it will be some time before they disappear.

Morello Cherry Trees Dying (*A. G. W.*).—No one can tell you the cause of the trees dying, in the absence of particulars relative to their age and the treatment to which they are subjected. Some trees are weakened by overcrowding and insects, others fail through want of lime and other minerals, while old trees wear out sooner or later. If you supply information on the points suggested, also repeat the character of the soil, the case shall have our best attention.

Begonias (*F. J.*).—You give no references, but we presume you allude to the papers read at the Begonia Conference at Chiswick last week. These will be published in the Journal of the Royal Horticultural Society, which is distributed free to Fellows of the Society, and surplus copies sold. We do not know what the price of the next issue will be nor when it will be published. You can obtain information by writing to the Secretary, R.H.S., 117, Victoria Street, Westminster.

Plants for Walls (*C. J. L.*).—We do not know of any flowering plants that would thrive and flower well against the walls of a stove that is "very shaded." Flowering plants require plenty of light to make their growth, for unless sturdy and thoroughly matured they will not flower freely. Euphorbia jacquiniæflora succeeds very well in Cucumber houses that are only used for that purpose in summer, but a Cucumber house in winter is much too hot for flowering plants. Abutilons would do in the Tomato house, but you give us no data whatever for guidance.

Tomatoes Failing (*X. Y. Z.*).—Persons who grow Tomatoes extensively for market year after year find it remunerative to change the soil periodically, removing some from the house to the garden or field and introducing an equal quantity from the field or garden. Some soils support the crops longer than do others, the difference being a question mainly of phosphates and potash. A mixture of two parts superphosphate of lime and one part muriate of potash applied earlier in the season at the rate of 3 or 4 ozs. to the square yard might have assisted your plants, but we presume the time has passed for it to be of any substantial use this season.

Tenants' Glass Structures (*Inquirer*).—Your questions could perhaps be better answered by a lawyer or surveyor than by us. Broadly speaking, tenants' structures are those which are not attached to the ground by bricks and mortar, and we should not recommend you to remove such houses against the wish of the landlord without legal advice on a specific case. Boilers when not set in brickwork attached to the ground are removeable, and there are plenty of such to be had. We have no particulars of the cost of heating greenhouses and other garden structures with gas. If any records on the subject are sent to us by gardeners or amateurs they will receive attention with a view to publication.

Ferns for Decoration (*T. D.*).—The following varieties will do well for winter decoration:—*Pteris serrulata*, *P. serrulata cristata*, *P. serrulata major cristata*, *P. Mayi*, *P. argyrea*, *P. albo-lineata* and *P. tremula*, *Adiantum cuneatum*, *Asplenium bulbiferum* (useful in a

young state), *Lomaria gibba*, *Davallia Mariesi*, *D. bullata*, and *D. Tycmani*, *Microlepia hirta cristata*, *Nephrodium molle*, *Nephrolepis davallioides* and its variety *furcata*, the old *exaltata* also being useful. *Polystichum proliferum* is also useful and effective in a small state. Had you stated what variety of *Aralia* you had that had grown too tall we should have been able to tell you how to propagate it. If you supply this information we will gladly do so.

Bilberries and Cranberries (*G. B.*).—The fruit is wholesome, and enjoyed by some palates. The reason why the plants do not grow in your district is probably because, as you say, it is "high and dry." They like moisture. The berries are subacid, moderately astringent, and agreeably flavoured, and contain mucilage, sugar, malic and citric acid, and an astringent substance, which exercises a tonic effect. The common Bilberry or Blaeberry (*Vaccinium myrtillus*) grows abundantly on the moors of England and Scotland, and produces berries of the size of Currants, of a bluish-black colour, covered with a mealy bloom. They are eaten either raw or in tarts with cream, or made into jellies with sugar. In Devonshire they are eaten with clotted cream. With the juice of the berries mixed with the bark of alder, powdered and mixed with alum, the inhabitants of northern Russia dye their hair of a bright red colour. The fruit of the Great Whortleberry (*V. uliginosum*) is large and black, but less juicy than the preceding, and neither so agreeable nor so wholesome, on account of its narcotic properties, which, when the fruit is eaten to any extent, cause headaches and vertigo; they are sometimes put into beer to make it heady, and, when fermented, they make an intoxicating liquor. The Cowberry, or Red Whortleberry (*V. vitis idaea*) is abundant on the dry, barren moors of Scotland. The berries are dark red, acid, and austere, and not so agreeable as either the Cranberry or Bilberry. They make an excellent jelly, which is esteemed for colds and sore throats, or to eat with roasted meat, for which latter purpose the Swedes use it extensively to venison, and consider it superior to Currant jelly. In Wales it is eaten with roast mutton. The common Cranberry (*Oxycoccus palustris*) grows in mountainous districts in the northern regions of the Old and New World, and is also found in many parts of Britain. The berries are Pear shaped, globular, often spotted, crimson, of a peculiar flavour, with a strong acidity. They are much esteemed in tarts. The American Cranberry (*O. macrocarpus*) produces fruit much larger than the preceding, and of a brighter red colour. The plant grows wild in many parts of America, but is also cultivated for its fruit.

Cropping Vines (*J. H.*).—You wish to know the reason of the bunches of Grapes being so much larger at the top of your Vines than they are towards the bottom and for some distance up the rods. This is by no means an uncommon occurrence, though we know of many exceptions. The bunches are the largest near the top because the wood is stronger and the buds from which the fruiting laterals grew were bolder than those much lower down. The evil, for an evil we consider it to be, is aggravated by leaving the leading cane too long at the winter pruning. The sap ascends to the highest point, forces the growths there, and these deprive the laterals lower down of the support that is essential to induce them to grow strongly and produce fine leaves and bold buds. When the balance of strength is lost to a material extent it is not easy to restore it. The strongest of the lower laterals only should be retained, and these trained not less than 15 inches apart along each side of the rod, and they may be allowed to extend more than the stronger ones above them. If there is room for the development of the leaves, three or four may be allowed beyond the bunches (if any), while the stronger laterals towards the top may be stopped at one leaf beyond the bunch and all subsequent growth promptly suppressed. About this time of the year the long lower laterals may be half shortened to "plump" the lower buds. In the spring the rods should be taken down and trained horizontally, or rather bent so that their ends are as low as they can be conveniently brought below the horizontal line, and there remain till the lower buds have pushed an inch or two of growth, then with great care place the rods up the roof. If you can give the lower buds the leaf you need have no fear about those towards the top lagging very long behind. It is a mistake to leave a great length of young cane for bearing when the Vines are to be trained on the spur system, also a mistake to denude the lower part, from the ground up to the roof, of buds, as some growth down to the ground causes the stem to thicken and equalises the sap throughout. The upper part of a house is, moreover, often warmer than the lower, unless thought is exercised in early and a little constant ventilation by the top sashes.

Names of Fruits.—*Notice.*—Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*W. Smith*).—Most of the fruits are insufficiently matured for naming, while the stalks of some and segments of others were broken, thus increasing the difficulty of identification. 1, Lord Suffield; 2, not determinable; 3, Cox's Orange Pippin; 4, Dumelow's Seedling; 5, perhaps Scarlet Nonpareil; 6, possibly Wyken Pippin. (*W. Mansell*).

—As you have sent summer shoots with the fruit, also described the flowers, we have been able to identify the variety as Sea Eagle.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*R. M.*).—We cannot name flowering plants from leaves alone. See the above conditions. (*J. W.*).—The lid of the box was broken and the pieces pressed down on the specimens, crushing them seriously. 1, A florist's variety of *Clematis*, which we do not undertake to name; 2, *Bignonia cherere*; 3, not yet identified; 4, crushed, possibly *Campanula garganica*; 5, totally insufficient; 6, *Achillea Ptarmica*.

COVENT GARDEN MARKET.—AUGUST 31ST.

MARKET very flat indeed, with prices much depressed.

THE SIZE OF FARMS.

HOME farmers, what of your balance-sheets? Are you still able to pay your way, or are you falling into arrears, which grow heavier year by year? If so, there must be a change in some way

or other; for if you, with a market at hand for all your best produce, cannot make farming answer, who can?

It is clearly understood that the class of farms we write for are kept in hand specially for the production of an ample supply of all that a well managed farm affords for the requirements of the hall, mansion, or castle, as the case may be, only surplus produce being sold, a fair market value being placed upon everything sent to the house for home consumption, also to the hunting and carriage stables. Whether such supplies are large or small it matters not, provided sufficient land and other means are available to produce them. Then comes the question if it is worth while adding sufficient land to the farm to obtain enough surplus produce for sale to cover expenses. Certainly it is; only remember that such produce must be of the best quality of a kind always in demand, for which there is a prompt and profitable sale.

"Profitable sale!" says the corn farmer. "Is such a thing possible for anything we have to dispose of?" Well may he say so, for his foolish persistence in devoting most of his holding to corn-growing is leading him to ruin as certainly as a thing can do which costs twenty shillings to produce and for which fifteen shillings only can be had in our best markets. In the third week of August an East Anglian farmer at Bury St. Edmunds Corn Market sold the produce of 16 acres of Wheat for exactly the same money as he obtained for that of 6 acres a year ago. This farmer is well known to us as a member of a farmers' club, where an address which we gave on the advantages of dairy farming over corn-growing was met by an assertion that East Anglia was not a dairy farming district. That address was given some four years ago. Corn-growing has gone steadily on; there has always been some profit on a good malting sample of Barley, but the struggle has become more and more severe, the depression deepens in intensity, and it really appears that the change in farming which is bound to come must spring from the ruin of many more men of the old school yet.

We have always held that a home farm should be so well managed as to be the model farm of the estate, where the tenants might see the best methods of culture and the best results. It should be something more than this. It should afford examples of what is possible in the way of advantageous change, having, on large estates at any rate, its butter factory supplied with milk from the home farm and from any of the tenants who can be induced to send milk, and we can hardly conceive of a tenant farmer who would not gladly avail himself of such a ready market for his produce. Some few landlords have tried it to the mutual advantage of themselves and their tenants; we would urge others either to do so too, or better still, to set going a co-operative factory, taking up many or most of the shares at first, then gradually allotting them to the tenants as they applied for them. There must in the future be something more than passive acquiescence in the situation, there must be positive effort to amend it. The interests of landlord and tenant are so involved that combined action is most desirable.

Another important adjunct to such home farms is a fruit evaporator. Lord Sudeley has shown at Toddington what wonders can be done in fruit growing and jam making. Of far greater general importance is the planting of free bearing sorts of Apples and the introduction of fruit driers or evaporators on all model home farms. Fruit farming and fruit evaporation have a great future in this country; let us do all that is possible to promote fruit farming without placing too much stress upon what has been done, or upon difficulties in the way. We are bound to break up the foreigners' monopoly of the dried fruit trade which has assumed such gigantic proportions, because every pound of dried Apples imported might just as well have been prepared from home-grown fruit in our own evaporators. As yet farmers generally are ignorant of fruit production in a systematic manner, to say nothing of fruit grading, of the paring, drying, and packing of Apples, which

affords employment to tens of thousands of labourers in winter in the United States of America, whence all our supplies of dried Apples come.

If the home farm can be enlarged sufficiently to lead the way to better things, to become practically a school of modern agriculture, showing by actual demonstration how to change, and what is worth changing for, it would indeed prove a boon to the tenants. A tenant farmer of limited—probably straitened—means cannot afford to indulge in speculative novelties which may lead to a heavy loss. That is why we so strongly advocate co-operation, in landlords leading the way, and so indirectly helping themselves.

WORK ON THE HOME FARM.

Thunder showers have brought on late-sown Swedes with a rush, so that singling has had to be pushed on as men could be spared from the harvest fields. There has been very little difficulty about this, as much of the corn in southern counties has been carted. So far there is no sprouted grain; better still, the Wheat is so hard and dry that home-grown samples will closely approach the best imported samples in quality. Holders of old Wheat are likely to suffer from this: reports of last week's markets show that they are already doing so, the old crop being much neglected and disparaged by buyers. The imperial average price on sales returned for the week shows a decline of 4d., which may in part be accounted for by the increasing quantity of old Wheat crowded upon the market.

Self-binders stand pre-eminent this harvest, with corn so erect that the work has gone on briskly without hindrance of any sort. As usual the gloriously fine hot weather has made some men over-confident, and on our long journeys by rail we have at dusk seen acres of Wheat cut and tied, but the sheaves have not been set up in shocks. This is wrong, for our fickle climate cannot be trusted, and it is a serious matter to have the sheaves saturated by a heavy thunder shower. Barley is bright in colour, with full plump grain, and good malting samples will be so plentiful that prices will probably have a downward tendency. The crop is a fine one, which will help many a struggling farmer to pull through one more Michaelmas.

Push on autumn tillage, every hour of fine weather now is a golden opportunity to be turned to the best account. Work double tides now; get the land clean, throw it up for winter, and rest when days are short and weather broken. Far better to do so than to spin out the ploughing throughout the winter—aye, till seed time is upon us in spring, as is so frequently done. When the corn is once in the stack leave it alone till autumn tillage is over; do not fritter away fine weather in premature corn thrashing, but turn to the land and keep to it till the farm is in thoroughly trim condition for the coming winter.

The time for sowing winter corn is upon us. Do not forget that early sowing means early reaping, a crop saved, land cleared in good time for autumn tillage. Do not sow an acre of winter corn in soil at all deficient in fertility without some manure. For land in fair heart 4 cwt. of superphosphate or basic slag per acre is sufficient now; if it is very poor add 1 cwt. of sulphate of ammonia.

REMARKS.

- 21st.—Cloudless early; more or less haze during the day.
 22nd.—Sunny morning; haze and cloud in afternoon.
 23rd.—Warm sunny morning; cloudy after 3 P.M.; rain from 6.30 to 7 P.M.
 24th.—Overcast early; generally sunny after 10 A.M.
 25th.—A little rain early; occasional sunshine from 11 A.M. to 2 P.M.; slight showers in afternoon, fine evening.
 26th.—Overcast early; sunny after 11 A.M.
 27th.—Occasional sunshine early; showery after 11 A.M., and continuous heavy rain from 2 P.M. to 7 P.M., and from 4.30 A.M. till after 9 A.M. on 28th.
 A warm and fairly fine week, finishing with an exceptionally heavy rain.—G. J. SYMONS.

TEN years ago the writer paid a visit to Lord Rosebery's beautiful English home in the fertile vale of Aylesbury, and after hearing Mr. J. Smith's paper on Plums read at Chiswick and referred to on page 184 last week a desire was awakened to see the trees again. Ten years since they were small and supported by stakes, but the same trees are now self-supporting in more ways than one, for they need no stakes, and pay their way—that is, give a good return on the outlay which has been invested in the plantations and the cultural care bestowed on them. The progress they have made is altogether satisfactory, and if there is a finer example of orchard Plum culture in the kingdom it will be worth a long journey to inspect. Evidently the soil is naturally adapted to Plums, for fine old trees, especially of Damsons (with an undergrowth of Aylesbury ducks), are growing round many a homestead. Probably the beautiful and fruitful condition of these suggested to the late Baron Meyer de Rothschild that he might both improve the appearance and increase the value of his estate by planting somewhat extensively. This was done, and done well, for Mr. Smith, then, and happily still, the gardener at Mentmore, is as sound a cultivator as Britain boasts, and the word failure has no place in his vocabulary. He is not the man to work without thinking, nor to undertake what is impracticable, and, after seeing his way clearly, he does his work thoroughly, and waits watchfully yet confidently for the issue.

It is a question of somewhat long waiting for profitable crops of Plums in the strong soil—clay with an admixture of chalk—eight or nine years elapsing from planting before any substantial amount can be realised; but the trees being on grass the cost of attending to them is not great, and when once they become profitable they continue so for two or three generations, as is evident by old established trees in the locality. Not far distant, where the land is lighter and drier, the trees bear profitable crops in three or four years, but soon lose vigour, and wear out long in advance of those growing in a more substantial food-holding medium. Strong soil, firm soil, well fed soil, are what Mr. Smith regards as the essentials for profitable crops of Plums over a prolonged period, and these conditions provided as at Mentmore the plantations distinctly contribute to the beauty of the landscape and enhance the value of the land.

As to beauty, what is more charming than say 50 acres of Plums when white with blossom? shining like a silvery, billowy sea in the sunshine of early spring; and what more satisfying than the harvest of purple and other colours which the varieties assume as they change for ripening in the summer and early autumn? Then the trees individually possess a beauty of their own, especially to the cultivator, in their characteristic forms, and open yet well balanced heads, full of fruit, for where light finds free access fruit follows, and it may as well be had, as it may be with very little trouble right through the trees as well as at the ends of the branches. The crop at Mentmore is not all outside show, and we have to go amongst the trees and look into them to appreciate the full bounty of the yield. Passing along the road and taking a general glance the crop does not appear a heavy one, but as we drive between the rows of trees we see that it is heavy enough for the fruit to be fine and profitable without being unduly exhaustive. A "glut" is not desired, but even in the great Plum year of 1878

Mr. Smith had no difficulty in selling his crop of 60 tons of fruit. Such overlading, however, "gives the trees a shaking," and they require time for recuperation.

As to profit, the late Baron was right in his forecast, and the Plum plantations on grass would now let as readily for £10 an acre as the surrounding fields would at £2 or even 30s. That is conclusive. It is no vague estimate founded on fanciful figures, but a verity based on experience in the actual sale of fruit. The plantations have been greatly extended since the estate passed to Lord Rosebery by his marriage with a lady whose grace and goodness brightened the district, and whose loss is still deeply mourned by the inhabitants of every creed and class. It is gratifying to observe that his lordship cherishes his princely home and its beautiful surroundings, and well-considered improvements in planting young trees and thinning older plantations, making roads, removing old and erecting new buildings have been effected, others being in progress, thus affording employment to many workers and adding completeness to his estate.

To return to the Plums. Stations are well prepared for the trees and planting is carefully done. They are securely staked, and bushed, *i.e.*, the stems protected with thorns or other sticks tied round them, against injury by sheep or rabbits, and for two or three years mulchings of manure take the place of grass to encourage free growth. This secured the grass is allowed to grow up to the stems, and sturdy, firm, fruitful wood follows in the firm soil. The trees are pruned after planting by shortening well back the long young branches, Mr. Smith being strongly opposed to waiting a year, with the consequent struggle for life the first season and some almost certain deaths, preferring a certain summer's growth of moderate extension, yet sturdy, for laying a good foundation in the trees. Those in a bearing state are also assisted from time to time by having the grass removed in a sufficient circle round them for admitting three or four barrowfuls of London manure. This is rammed down firmly and covered in spring and the grass again allowed to grow. It is soon trampled hard by the sheep, an increase of fibrous roots follows, and the trees improve in colour, make freer growth and afford finer fruit. The manure costs 5s. a ton delivered, then there is the labour, but the outlay is a profitable investment, in other words this work of culture pays or it would not be done.

The trees are pruned, or such as may need it, on simple and sensible lines. There is little, if any, shortening of the branches after the trees are formed, and severe thinning is never resorted to, for the sufficient reason that it is not necessary, as by timely action in removing a few branches, which if left would be inimical, any approach to overcrowding is averted. That is the whole secret of the matter—preventing an evil instead of suffering it to occur, then having a general slash to remove it. There is an enormous difference in the two methods as affecting the fruitfulness of trees, yet numbers of would-be fruit growers are provokingly slow to grasp the significance of this difference. Only a comparatively few appear to fully appreciate the importance of a thin disposal of the main branches of fruit trees; not by the removal of a number to relieve the crowding, but by the immeasurably better and easier way of never permitting anything approaching a thicket to occur. When a thicket does occur, thinning, though it should be done, can only be regarded as the lesser of two evils, the greater being the original mistake of rendering the work necessary. Among the thousands of fine young Plum trees under notice—trees varying from four or five to fifteen or twenty years of age, there are few that need more than five minutes spending on them in pruning, but this little time will be given instead of waiting till thrice the cutting out would be requisite; in the meantime serious, if not irretrievable injury, being done in limiting the fruit-producing power of the trees.

Some of the best varieties of Plums grown at Mentmore were named by Mr. Smith in his Chiswick paper. In the

plantation more particularly inspected, hundreds of trees of Green Gage were pictures of beauty in character and productiveness, as were Damsons. These are profitable for orchard culture when the fruit is good and fairly and honestly marketed. No matter how plentiful Plums may be and the market overlaid from the grower's point of view the consignments from Mentmore, however large, are bought up at once, because the large buyers know they are all the same right through the bulk, and that there is full measure, and no thick pads of straw ostensibly to prevent the fruit bruising, but really for something else. A great deal is said about market dues and salesmen's customs eating away profits from growers, but Mr. Smith has not a word to say against his treatment in Covent Garden, and he is one of the last men in the world that would submit to be treated unfairly. Damsons have been mentioned; four varieties are grown—the Kentish or Crittenden, small round, borne in clusters; the Shropshire, a little larger and somewhat oval; the Prune, very large, oval, tree somewhat spreading; and Worcestershire, also large and similarly shaped, tree more upright in growth. Bradley's King is not yet included in the collection, and those named give satisfaction. The trees are planted 22 feet apart.

Apples are also extensively grown, but those inspected were as bushes in the fine kitchen garden. Rows of Worcester Pearmain were aglow with scarlet fruit. Cox's Orange Pippin was bearing highly coloured fruit abundantly, as were other well-known useful varieties; but less known and deserving of special mention were Bismarck, clustered with magnificent fruit, and Seaton House (named Niton House), the bush trees being 10 feet high, productive, and the fruit, which somewhat resembles Dumelow's Seedling, keeps till late in the spring. Lane's Prince Albert is a favourite here, and all over the district, because of its certainty in bearing full crops of fine and long-keeping fruit. Pears were less plentiful, but several trees were bearing well. Those of the favourite Marie Louise were failing, probably because worked on the Quince stock, and to insure healthy growth over a long period they must be on free stocks or double grafted.

A great deal could be written about other departments if the printers would wait, but they will not; the noble sweep of lawn, with fine trees and terrace; the magnificent view—a park-like panorama of thousands of acres, bounded by the distant Chilterns; the beautiful tropical garden and picturesque shrubbery recesses; the thrifty Conifers—Corsican Pines 60 feet high, one having to come down; the rapid growth of Wellingtonias raised from seed sown only fourteen years ago, and now 30 feet high, with stems 3 feet in circumference; the splendid vegetable crops, and so on; but whatever is omitted, the range of glass in the kitchen garden now in course of erection by Mr. Boyd must have mention. When completed it will extend some 600 feet, with a central dome. This is already up, as are spacious vineries, with Vines making a start for future fame. With all these features Mentmore is now a truly noble place, and when other improvements are carried out and the hundred acres of fruit trees in full bearing, as scores of acres now are, it will be necessary to travel far to find its equal, taking it all in all, in our fair and fertile country.

Whoever may visit Mentmore now and not be satisfied will be hard to please. Possibly there may be a floral enthusiast here and there who might like to see the fine lawn dotted with flower beds and thereby spoiled. That is not the place for them; but in another garden within view—Mr. Leopold de Rothschild's at Ascott—such a wealth of flowers may be witnessed as will not soon be forgotten. Truly gorgeous are the Begonias, and with golden Conifers in thousands, and almost all other flowers that can be thought of, also with shrubs of such shapes as could only be conceived by a Dutchman, we have in front of the quaint and picturesque mansion a scene which for brightness and diversity it would surely be difficult to match. Besides all this there is the glass, and perhaps ten thousand Carnations, which Mr. Jennings grows so well, as he undoubtedly manages well everything in this remarkable garden, which Mr. Smith describes as a "Paradise of flowers." It is mentioned because it was through his kindness that it was seen during a spare hour which was found after a quick inspection of his excellent work at Mentmore.—J. W.

NARCISSI—PLANTING OUT AND IN POTS.

THE season for planting has again returned, and should not be delayed much longer, as Narcissi are early, and many of them abundant, root-producers. It has been the experience of most growers of these useful and charming flowers that animal manures are prejudicial. That, I think, is a generally accepted fact. It is also a proved fact that a strong holding soil produces the finest foliage and bloom and some go so far as to say that a light dry soil

is not at all suitable for many of the finest sorts. I cannot confirm that statement, as I find with proper attention they succeed very well on just such a soil; and however poor the soil may be naturally, I should not hesitate to plant with every hope of the plants succeeding and improving year by year.

Groups of Narcissi are very charming in mixed borders and on grass. The Daffodil is *facile princeps* among bulbous plants. But in order to obtain the best results in the form of strong foliage and the largest flowers on long stalks it is by far the best plan to set apart a plot of ground in order to grow the collection. The ground must be deeply dug, or, preferably, double dug, and all lumps broken down in the process. If any dressing is given to the soil let it be leaf soil or the best portion of the compost heap, including the old soil in which Chrysanthemums have been grown. I have planted the bulbs as the digging progressed, and have also sown them like Beans in deep drills drawn with hoes, and so far as results go the one way proved as good as the other, while the last named has the advantage in being more expeditious.

The question as to how deep the bulbs ought to be planted depends somewhat on their size. From 3 to 6 inches deep is quite sufficient. I invariably find that the young bulbs push the older upwards, so that after three years' growth many of them are close to the surface of the soil. The deep planting of such sorts as *Poeticus ornatus* is, I think, distinctly inimical to the well-being of the plants. They do not flower so well, nor do they increase in the same ratio as shallow-planted bulbs.

The distance apart at which to plant must be guided by circumstances. Sir Watkin ought to be planted further apart than Emperor, because the former increases more rapidly and the growth is more robust, 6 inches for the former and 4 for the latter being a fair distance, with a foot between the rows. Then take the *Poeticus* family: *recurvus* increases so rapidly, and grows with such vigour, that from 6 to 8 inches is not too wide. The double form may go in at 5, while *ornatus* at 3 inches is not too wide.

The beds will require hoeing before September is out, and again in early spring. At a suitable period in April I give a slight dressing of superphosphate of lime, and I have found this to exert a wonderful influence on the plants. For the later sorts, if the weather is very dry at the end of April or early May, a soaking of water will be of the greatest benefit. During the summer and autumn months, hoeing and keeping the rows clean is all that is required; and in April, when growth has again progressed somewhat, another dressing of superphosphate or of fresh soot, or of sifted soil from the decayed compost heap, will be needed to keep the plants improving.

The present time is also the period for beginning the necessary work on the portion of the stock which it is intended to grow under glass. Narcissi are the easiest of all bulbs to grow in this way, and no flowering bulbs can surpass them for general usefulness. To insure success none but the best quality bulbs ought to be grown. I do not know that it matters so much as to size, but certainly the bulbs ought to be thoroughly well ripened by first of all lifting early and then allowing them to get well dried on the surface of the ground. These are points of supreme importance, the neglect of which no after good management can make up for. Any good open soil does to grow them in. The pots require to be well drained, as the plants like a good deal of water when in full growth. It is a decided mistake to allow them much root room. Three large Horsefieldi or Empress bulbs do well in a 4-inch pot, or five in a larger size. The bulbs will be at once touching the inside of the pot and each other. I have in one season grown many hundreds of common sorts in ordinary 4-inch deep cutting boxes, with each bulb touching its near neighbours, and nothing could be better than the result. I feed the plants well when they are in full growth, and keep them always moist at the root. Even such a stubborn sort as *poeticus recurvus* does excellently in this manner. Expensive varieties ought not to be forced hard. For instance, I would not force either Emperor, Empress, Horsefieldi, or Sir Watkin; but by bringing them on slowly there is no difficulty even in the north in having them in flower in March.

What to do with the plants after flowering may be a question of interest to many. I invariably plant them out. As a matter of fact, most of the plants are flowered in a greenhouse temperature, so that the change is not so very great; but some are occasionally forced in heat to the finishing of the flowering, and even these may be planted out with impunity. With valuable sorts I plant the whole potful out without breaking roots or ball. To do either causes a greater check than is necessary. The year succeeding the bloom is poor from these, but they rapidly improve thereafter under kindly treatment, and the third season the flowers are again at their best.—R. P. BROTHERSTON.

THE CULTURE OF ORCHIDS FOR CUTTING.

"L'ORCHIDOPHILE" contains some reflections on the subject of growing Orchids for cutting which those who imagine there is a fortune to be made out of the process might do well to inwardly digest. "A certain number of readers have asked us," it says, "if the culture of Orchids for cut flowers would be a good speculation for an amateur. We doubt it. All those who import have an interest in recommending it. Where would the thousands of plants that are placed on the market go to if, from time to time, an amateur could not be induced to embark in a speculation which has at least the merit of absorbing a large number of plants? All those who strive desperately to induce them to do so have only," our contemporary continues, "the sale of their plants in view. What does the failure of their client matter if they have realised some benefit themselves? All plants are good for cut flowers when the dealers have a large stock of them, and species are recommended for the purpose that are quite unsuitable. If a few amateurs have not realised benefits from cut flowers, but diminished their expenses a little, it is certainly not with the plants the importers have enumerated. It may be affirmed with certainty that a speculation based on the plants recommended by those interested in them would be disastrous.

"The sale of Orchid flowers is fairly active about Paris; several horticulturists grow plants for this purpose. Duval of Versailles has the most important cut flower establishment. All there is managed economically and practically. Well, we are convinced that he does not realise any benefit from cut flowers. At Paris the period of the sale extends from November to June. All which flower after are unsaleable. The sale during the season is not regular; one day the florists are disposed to pay absurdly high prices, the next they offer wretched ones. The sale of choice flowers is very uncertain; a great wedding will increase it 50 per cent. The amateur who cuts flowers under the impression that he is going to sell them is sure to be unsuccessful. How will he go about it? Will he go from shop to shop offering them, exposing himself to rebuffs? or will he employ an intermediary for this task? The flower is cut and it must be sold. The amateur will not know in what state the flowers have arrived, and we could cite among our subscribers many who have never received a halfpenny for what they sent. Either the flowers arrived badly packed, too late, or frozen, or the agent forgot to account for them.

"To have one agent for cut Orchids is not practicable. We have tried to sell flowers in Paris. We have offered them through an agent to florists in different parts. They paid a good price for those which they came to take from us, but they would not give anything for those which we offered to them. 'If we want Orchids,' they said to us, 'we know quite well where to find you.' The Orchids which sell well as cut flowers are not very numerous. *Cattleya Trianae*, *C. Mendeli*, early *Mossiaes*, *labiata*s flowering in November or March, *Odontoglossum crispum*, and *O. Pescatorei* form the basis of the trade; the rest are only accessories. We repeat that in our humble opinion the amateur who sells flowers which he does not want may diminish his expenses; he who cultivates them for the purpose must be ranked as a tradesman, and sad to say there are not many who enrich themselves at the trade."

Our contemporary does not, it will be seen, think that Orchid growing for the sale of cut flowers is a paying speculation, and reflects severely on dealers in imported plants. Let us hope they are not quite so bad in England as they are represented to be in France.

STENOGLOTTIS LONGIFOLIA.

THIS is a lovely cool house Orchid, which appears to be little known or cultivated. It is a plant of considerable merit, easily grown, readily propagated by division, and lasts in flower for a couple of months. Early in the year when growth commences it should be potted, three growths in a large 60 or small 48-pot being sufficient. The compost should be peat, leaf soil, sphagnum, and a little cow manure. If placed at the warmest end of the cool house it will grow readily, and will commence to flower about August. The leaves are about 6 inches long, light green, the plants having somewhat the appearance of *Disas*. The spikes are erect, commencing to bloom 6 inches from the plant. The flowers are small

and produced in quantity, and are of a pretty bluish purple. The lip is fimbriated and spotted with dark purple. The spike continues to elongate and produce flowers for a considerable time, thus the plant is a good addition to any collection. It is a native of Natal, and requires to be kept drier after flowering than it is when in bloom until growth commences again. Several plants were recently flowering in the cool Orchid house at Kew, together with the smaller *S. fimbriata*.—C. K.

LÆLIA CRISPA.

FLOWERING early in the autumn as this plant does it is always a great favourite with Orchid growers, as it helps to fill up a kind of gap in the Orchid year. *Lælia crispa* has a history, and is consequently interesting on that score. It is a native of Brazil, and was introduced in 1826 by Sir Henry Chamberlain, who sent plants to the Royal Horticultural Society's Gardens at Chiswick. In 1827 it flowered for the first time in England, at the Chiswick Gardens, and was named by Dr. Lindley *Cattleya crispa*, under which name it is figured in the "Botanical Register," t. 1172, and the "Botanical Magazine," t. 3910. This charming *Lælia* grows at an elevation varying from 2000 feet to 3500 feet. The pseudo-bulbs are 8 to 12 inches high, bearing a stout solitary leaf nearly a foot in length; the spikes, carrying four to six

FIG. 29.—LÆLIA CRISPA SUPERBA.

flowers, rise from a yellowish green sheath. The sepals are white with revolute margins. The petals are broader than the sepals, white tinged with purple at their bases; margins wavy and crisped. The lip is very beautiful, three-lobed, the side lobes encircling the column, white marked with yellow and purple on the inside; centre lobe longer and reflexed, with a fine crisped and waved margin, deep red purple with dark purple veinings. The whole flower is about 5 inches in diameter. There are several fine varieties of *L. crispa*. A finely crisped variety was exhibited at the meeting of the R.H.S. at Westminster on August 9th by T. Statter, Esq., Stand Hall, Manchester, under the name of *L. crispa superba*. The lip, which was velvety purple shading to mauve, was beautifully crisped and fimbriated. Fig. 29 represents it.—C. K.

PROFITABLE USE OF WASTE LAND.

GARDEN ALLOTMENTS AT CARDIFF.

HAVING been called upon lately, in conjunction with Mr. Stephen Treseder, Pwllcoch, Cardiff, to adjudicate on some garden allotments in Cardiff, for the best cultivation of which prizes had been offered, a short statement may be of interest as showing what may be done under the powers of the Allotments Act. The

garden allotments, which are held and worked by labouring men, cannot be said to be as yet very numerous. They are situated in three separate districts of the town, in each of which the conditions are somewhat different. In one district, known as Cathays, the experiment has been made in a large field of good soil, leased by the Corporation from the Marquess of Bute, and re-let in allotments of 20 poles each to working men. The whole of the land available at present has been taken up. In the district of Canton and Grangetown the providing of allotments has been connected with another instructive experiment.

In Cardiff, as in other towns, the problem of how to dispose of house and road refuse has been the cause of much perplexity. Mr. Woosey, the Superintendent of the Scavenger Department of the Corporation, resolved to utilise it in making up patches of low-lying and comparatively valueless land, and letting it out for gardening purposes. In the Canton district the ground so used was a piece of common land belonging to the Corporation, and there the land is made up to the height of several feet by the cartage of house refuse, and covered over with road scrapings, and was let out in allotments of 20 or 40 poles to about forty labouring men, and has been found to answer the purpose very well, the ground being thoroughly cultivated and yielding excellent crops.

At Grangetown the Corporation had no land to put to use in this way, but they obtained Lord Windsor's consent to use about 3 or 4 acres of ground belonging to him near the river Ely, which lay so low that it was frequently covered by the tides. The conditions of the arrangement were that the Corporation should have the land for seven years for nothing, and at the end of that time it should revert to his Lordship. They at once proceeded to raise it level to the extent of 4 feet by a deposit of house refuse, which they covered over with a layer of road scrapings; and the land so formed they let out to some thirty labourers in allotments of 20 poles each. This ground has been cultivated by them for the last three years, and has been found most productive. On the occasion of my visit I found it covered with vegetables of splendid quality. Each tenant had stocked his ground according to his fancy. All of them had fine plots of Potatoes, Cabbage, Cauliflower, Onions, Turnips, and Carrots, while some had Peas, Broad Beans, Scarlet Runners, Marrows, Celery, and sweet herbs. One man had hundreds, aye, thousands, of young Orange plants from 2 to 3 inches high in his allotment, and as healthy as if they had been growing in their natural habitat. The ground was manured with decayed Oranges, the seeds germinated as freely as Oats, and the old man did not like to pull them out. In several cases the early crop of Potatoes were off, and the ground planted again with Broccoli, Savoys, and other crops. Nearly every plot was clean, tidy, well cultivated and manured; some of them had been remarkably well worked and kept. The cultivation and tending of the plants is done chiefly in the evenings, and the labourers who hold the allotments appear to take great interest in the work.

The rent paid for the allotments is 1s. per pole, or £8 per acre; and there cannot be a doubt that the holders not only provide themselves with abundance of good vegetables for their tables, but are able to sell a considerable quantity. While all the allotments were managed creditably, the best were those on the plot of made-up ground at Grangetown. It may be hoped that the Corporation will be able to secure some more of the low-lying land to turn to equally profitable account; and local authorities elsewhere, who have waste land in their neighbourhood, might take a hint from what is being done in Cardiff.—A. PETTIGREW, *Castle Gardens, Cardiff*.

SOME TROUBLESOME PLANTS.

THERE must be as much pleasure in making a troublesome plant grow as in taming a shrew (of the former only have I had experience), and so, when I hear of a troublesome plant worth growing, I get it, and with a little wheedling and coaxing, I stoop to conquer. May I tell you how it is done with *Heuchera sanguinea*, that disappointing and yet most beautiful plant? It blooms freely with me all the summer, and in May, with a profusion of strong straight shoots 2 to 3 feet long, it was a splendid sight, the envy of the florists about here who fail to induce it to flower. I obtained a plant the year Mr. Ware sent it out, and now it has a large progeny. I soon found that it was best to pull two-year-old clumps to pieces in the autumn and replant in heavyish rich soil, and in the growing season to give the plants an occasional dose of liquid manure. Plants that make poor growth, and have small leaves (a sign that they are starved) do not bloom. I am writing with the experience, and therefore with the impudence, of a beginner on hardy plants, so I crave the indulgence of those who know a "Deal" better than I do.

As to *Eremurus Bungei*, which was so much admired in my stand of thirty-six bunches at Chester, I do not think I shall find

any difficulty with it or with *E. himalaicus*, which Mr. Ware says truly is "one of the most majestic and beautiful of hardy plants," at least I find it so. My spike was about 6 feet long, with about 2 feet of creamy white flowers at the top, each flower nearly as large as a shilling. *E. robustus* is like it, rather stronger in growth, and with pale pink flowers. *E. Olgæ* I have, but cannot write about it, my plant, I imagine, being too young to reveal its capabilities. I do not know how many years these plants take to come to maturity, but the lowest priced ones will disappoint the purchaser who looks for bloom year after year, and finding none, will associate it with *Heuchera sanguinea*, and declare it a fraud.

There are two difficulties in the way of growing the *Eremuri*—subtraction from one's purse, and the attraction the plants have for the insidious slimy slug, which finds its way into the crown before it gets above the ground. My *E. robustus* was spoilt this year by this creature. I do not think as some do that moving them hurts them—the plants I mean, for my slugs are generally injured in removal. My plants did not bloom, though they made a feeble attempt to do so. They were rather exposed to winds, and this they cannot stand. I carefully uncovered their long fleshy roots last autumn, a difficult and nervous thing to do, for the roots strike deep and are long and brittle, and replanted them all in a spot sheltered from winds in good deep soil 4 feet at least, and they could not have done better. Autumn is the time for planting, now if possible.

Then, *Tropæolum speciosum* favours my righteous dealing in two places, one in the *Rhododendron* bed shaded from sun by a Laurel hedge; the other in front of a window (my wife's store-room window, so it does not matter). I never thought when planting that it would grow all over it and among the Ivy above and on the side. This faces east, and the south side of the house keeps the sun off for the greater part of the day. It seems to me that all it needs is shade, heavyish soil, and plenty of moisture.

Then, again, *Zauschneria californica* grew rampant in a sandy sunny border, blooming gloriously, till I thought to decorate my rockery with it, with more thought for the rockery, I am afraid, than my plant, and so it sulked. It wanted all the glory and all the sun it could get, and did not like to be put in the shade; but now it is happy again in the old sunny spot.

Aquilegia glandulosa has been in the same place, on the edge of my little bog garden, for some years, and does not deteriorate. It seems to like moisture and partial shade, the same as *Trillium grandiflorum*, its close neighbour.

I suppose no one finds a difficulty in growing *Ramondia pyrenaica alba* who has tried a stony bank or even on the level, provided it is kept moist and out of the sun. I have a nice lot of seedlings, but when will they bloom? Growing these must be like planting trees for one's successor. Ah! says my florist brother, how about *Gentiana verna*? Well, I have not got it to bloom yet. I have not had it long enough, but some day I shall report progress. I have learned and practised all that the Journal has told me, so it is thriving. Now you may grow anything if you go the right way about it, but this means patience, perseverance, and sometimes—my wife says "sometimes" is not the word for it—expense.

About judging herbaceous flowers I agree with Mr. Garnett that too many bunches or spikes of one variety weaken a stand, and only when they are quite distinct should they be included in the same collection, but they are admissible. The arranging, of course, is a matter of taste, but it must not be forgotten that it is an exhibition of flowers, not a table decoration. What more beautiful exhibition of cut flowers can there be than a stand of thirty-six bunches as shown by Mr. Burrell of Cambridge? There is this to be said in favour of Mr. Garnett's plan, in which he displays consummate taste, that you have not to denude your garden of flowers. In East Anglia the competition in these classes is very keen. A few years ago we used to wrangle and quarrel as to the interpretation of both "hardy" and "herbaceous," but the question seldom arises now, not because we have grown better tempers but because we grow flowers better, and in improving the one it follows, I hope, that the other must improve. At Diss we have classes for bunches and also a class for twenty-four hardy perennials, one or two spikes of each variety, and a very interesting and instructive class it is, but of course you don't get the grand mass of colour that you do with bunches.—F. PAGE ROBERTS, *Scole Rectory*.

JUDGING HERBACEOUS PLANTS.

I HAVE been interested in reading the articles on the above subject, as I think it is one requiring attention. In my opinion many mistakes and complaints arise from the word "herbaceous" not being thoroughly understood by many exhibitors; nor are some good judges of other garden produce capable of giving a satisfactory decision when judging

stands of herbaceous plants, because they have not cultivated them largely, therefore do not know if the blooms are annuals, biennials, perennials, bulbous, or strictly herbaceous. I have competed in a class for these flowers when the prize was awarded to a stand containing a bunch of shrubby Veronica, also a bunch of annuals, while my own and others which I considered were in accordance with the schedule, twelve bunches of herbaceous or perennial flowers, distinct kinds being required, were passed over.

I agree with Mr. Garnett that all exhibits should be staged so as to show the growth and habit as much as possible, and the names plainly written for the benefit of all concerned.

I would not allow more than one variety of any flower to be shown in the same stand; say if *Lilium auratum* was staged, all other Lilies should be excluded, and so on. If schedules were worded in the following manner I think the meaning would be plain to exhibitors, judges, and spectators:—"Twelve, twenty-four, or thirty-six, bunches of herbaceous, bulbous or perennial flowers, distinct kinds, flowering shrubs excluded."—DEVON.

JOTTINGS ABOUT LONDON PARKS.

WATERLOW PARK.

AMONG the many open spaces recently acquired by the London County Council the above park occupies a prominent position. It is situated on the heights of Highgate, a picturesque northern suburb of the metropolis, and is, perhaps, for its size the most beautiful lung of London. Although less than a year old, as a public park it has become the favourite resort of thousands of residents in the northern suburbs, and when better known it will probably be visited by even a larger number of people. The natural beauties of the park are, perhaps, unequalled around London, as it is situated in a neighbourhood which still retains a certain amount of rurality. The park, it may be of interest to mention, was the gift of Sir Sydney Waterlow to the London County Council, by whom it was opened in October last. At present it is some 30 acres in extent, a portion of which is occupied by fruit houses, an orchard, and what originally was a kitchen garden. The surface is beautifully undulated, and winding walks abound, these features adding considerably to the scenery. Apart from its present characteristics there is an historical feature of no mean interest connected with Waterlow Park. It was there where the famous Nell Gwynne resided. Although, as may be expected, the house is at present in a somewhat dilapidated condition, steps to restore the building are being taken, and a portion of it will be occupied by some of the park employés. There exist in the grounds the bath in which Nell Gwynne was accustomed to take her matutinal dive, also the foundations of her favourite summer house. These items are mentioned as likely to be of interest to the general public outside the gardening world.

What concerns us most here, however, are the horticultural features of the park. For many years prior to the place being opened as a public resort the grounds had been allowed to fall into a neglected condition, and consequently great things as regards making a fine display could not well be expected in the short space of less than a year. But the change has been wonderful. Under the able management of Mr. Richard Curle, the Superintendent, vast improvements have been made. The twenty years' experience Mr. Curle had at Sefton Park, Liverpool, are well brought out in the present instance. He must have worked hard and assiduously. Those who have not seen the park since it was first opened could scarcely realise the improvements made. There are no series of elaborate stereotyped beds such as one is accustomed to see in many public parks, but a wonderful variety of flowers, fruit, and shrubs that cannot fail to interest the most careless visitor.

On entering the park from the Highgate side, near the famed St. Joseph's Retreat, the eye is at once attracted by a remarkably fine bank of flowers. A better display could scarcely be seen anywhere. The border is of a winding character, rather steep, about 30 or more feet wide, and perhaps 100 yards long, the back being well planted with trees and shrubs. In the rear patches of African Marigolds, Dahlias, annual Chrysanthemums, Zinnias, Tobacco plants, and various annuals are most effective, whilst the front portion is occupied by rows of John Roberts Fuchsia (very fine and free flowering), variegated Pelargoniums, dark-leaved Beet, Pyrethrum, and blue Lobelia, the two last-named being planted in the form of a triangle. A plant of *Cineraria maritima* is dotted in the centre of each patch of Lobelia, and a dark-leaved Beet in every triangle of Golden Feather, the effect being exceedingly good. On the opposite side to the above-mentioned bank is another similarly planted, and there are many other borders equally effective. On a terrace near the old house already alluded to there is a magnificent bed of Fuchsias, and close by a remarkably fine specimen of the Maidenhair Thorn (*Cratægus oxyacantha pteridifolia*). The mixed system of bedding, now so fashionable in public gardens, is much favoured in Waterlow Park, and some excellent arrangements may be seen there. These beds are always bright, informal, and never fail to please the most fastidious tastes. Specimens of Yuccas, Palms, Eucalyptus, and other plants are dotted on the grass, but owing to the exposed position many of them suffered severely through the rough winds which prevailed last week.

Not the least important feature in Waterlow Park are the herbaceous borders, situated in the original kitchen garden, but now being utilised for the production of spring-flowering plants. Mr. Curle obviously recognises the fact that hardy flowers have a future, and with that object in view he has established the borders mentioned. These are now gay with numerous flowers, and will remain so until late in the

autumn. Huge clumps of perennial Sunflowers, masses of Brompton and East Lothian Stocks, *Anemone japonica* and its white variety, *Sedum spectabile*, *Pyrethrum uliginosum*, and numerous other plants are now flowering profusely, making a feature not often seen in a public park. It is specially gratifying to note this fact, and it is to be hoped that the London County Council will continue the good work begun, and make the borders of hardy plants a notable feature in this and other parks.

Still another interesting and uncommon feature in Waterlow Park remains to be chronicled—namely, the fruit trees and vineries. There are many Apple and Pear trees, the majority of them now carrying an excellent crop of fruit. The whole of this is given to various hospitals and infirmaries, no less than 130 pecks of Pears, besides Apples and Grapes, being disposed of last year in this manner. Among the recipients of such produce last year were the Children's Convalescent Home, Highgate; St. Pancras Workhouse Infirmary, Great Northern Hospital, Temperance Hospital, Hampstead Road; North-Western Hospital, University College Hospital, and Holborn Union Infirmary. What could be more satisfactory? Could not a portion of other open public spaces be similarly utilised? Several vineries containing Black Hamburg, White Hamburg, Lady Downe's, and Muscat of Alexandria, all carrying a good crop of medium-sized bunches, are also noticeable, and attract considerable attention. An estimate, however, is now being placed before a Committee of the Council to make various alterations in the vineries, and turn them into a large show house, for which purpose they are admirably adapted.

Chrysanthemums are likewise to be a feature in Waterlow Park. There are some 1500 plants now receiving close attention, and all are looking the picture of health, so a fine display may be anticipated in the course of a few weeks. It may be of interest to add that a splendid view of the metropolis, possibly one of the best available, can be obtained from a portion of the grounds in Waterlow Park.—C. C.

ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 6TH.

THE fact of the holiday season being in progress did not militate so severely against the present gathering as to deprive it of all interest; on the contrary, there was an extensive display of excellent fruit, several varied and brilliant exhibits of Orchids, a good collection of Gladioli, and several groups of hardy flowers.

FRUIT COMMITTEE.—Present: P. Crowley, Esq. (in the chair), with Dr. Hogg, and Messrs. Harrison Weir, J. Cheal, G. Taber, W. Warren, A. Dean, W. Bates, W. H. Divers, G. Norman, H. Balderson, G. Wythes, G. Sage, G. Reynolds, H. J. Pearson, J. T. Saltmarsh, G. Bunyard, J. Hudson, T. Francis Rivers, and J. Wright.

A very fine display of fruit was arranged on the side tables, notably by Messrs. G. Bunyard & Co., whose Apples were remarkable in size and appearance. Mr. W. H. Divers also had a notable collection of Peaches and Nectarines, and Mr. W. Miller, Ruxley Lodge, exhibited a miscellaneous collection of considerable merit.

Mr. W. Palmer, Junction Road, Andover, sent fruits of Triumph × Hero of Locking Melons, but of no particular merit and therefore passed. Mr. W. Weir, Acton Park Gardens, Wrexham, sent a good bunch of a large black Grape raised from seed received from the Cape of Good Hope, and therefore named by him the Cape Muscat. It is a variety of promise, some of the ripe berries possessing Muscat flavour, and the Committee desired to see it again later in the season.

Mr. E. Burnand, Woodcote Road, Wallington, sent a dish of small Tomatoes named "Sabine's Choice." It appeared to be the ordinary Peach Tomato, and no award was made. Mr. Robert Owen, Castle Nursery, Maidenhead, sent six fruits of a large Tomato named Ponderosa, but the colour—a dingy crimson—was not approved, and no award was proposed for the variety. Mr. R. Dean sent from Ealing a fine bunch of Conference Tomato, rich in colour and good in quality, and a vote of thanks was accorded. J. Bucknall, Esq. (gardener, Mr. W. Wright), sent a box of large Sea Eagle Peaches, for which a cultural commendation was awarded. Mr. G. Wythes sent a dish of large fruit of Pond's Seedling Plums gathered from a standard tree. They were very good indeed, and a vote of thanks was entered for them. Mr. Cooper, Lewis Road Nursery, Brighton, sent a seedling Apple, but of no special merit, and it was passed. Mr. J. Bowerman, Hackwood Park, sent fruits of Owen's Seedling Apple, medium sized, fairly coloured, but soft, and no award was made. Mr. R. Dean sent a dish of Lord Grosvenor Apple from a small bush tree (vote of thanks). Mr. Harrison Weir sent Duchess of Oldenburg Apples to show the change that had resulted from grafting. This was so complete that there was not the remotest resemblance to the Duchess in either of the fruits. The case appeared to be regarded as a phenomenon, and was relegated to the Scientific Committee.

Mr. Bunyard placed fine looking fruits of Lady Sudeley Apple on the table for testing the quality. They were good, but not equal to Irish Peach, and only kept for a short time in good condition (vote of thanks). Major Thornhill, Stanton-in-Peak, Bakewell, sent a new Pea of good appearance, and it was referred to Chiswick for trial. Mr. Wythes exhibited a dish of Veitch's Success Pea, evidently a productive variety, for a certificate, as the variety had received three marks in the Chiswick trials. After a good deal of discussion a certificate was granted, whereupon Mr. G. Bunyard placed a dish of fine Scarlet Runner Beans on the table for a certificate on similar grounds, but this was not

granted. Surely the time to grant, or at least recommend, certificates, is when the crops are growing in the Gardens, as they are inspected when in the best condition.

Mr. W. H. Divers sent a collection of ten dishes of Peaches and six of Nectarines, very fair and mostly well coloured fruits, and a silver medal was unanimously recommended. The varieties were of Peaches Prince of Wales, Sea Eagle, Bellegarde, Violette Hâtive, Crimson Galande, Lord Palmerston, Princess of Wales, Barrington, Dymond, and A Bec. Nectarines: Dryden, Lord Napier, Rivers' Large Elruge, Pineapple, Spencer, and Prince of Orange.

Messrs. George Bunyard & Co. exhibited seventy-five dishes of Apples, including twelve baskets; also Pears, Peaches, and Plums. Among the Apples, very fine indeed were Duchess of Oldenburg, Grenadier (extra), Potts' Seciling, Lady Sudeley, Golden Spire, Ecklinville, Worcester Pearmain, Stirling Castle, Lord Suffield, Domino, Washington, Peasgood's Nonesuch, New Hawthornden, Warner's King, and richly coloured Bismarck. A silver-gilt medal was unanimously recommended.

Mr. J. Miller, gardener to Lord Foley, Ruxley Lodge, staged twenty dishes of fruit, including Grapes, Melons, Peaches, Nectarines, and Figs, all in good condition; a silver medal was recommended.

Messrs. J. Cheal & Son sent a collection of ornamental Crabs, including John Downie, Dartmouth, Transcendant, Yellow Siberian, and others. A vote of thanks was accorded. A large collection of Kidney Beans was brought from Chiswick.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair), Messrs. B. Wynne, D. P. Laird, R. Dean, H. Herbst, C. T. Druery, G. Phippen, H. B. May, G. Gordon, N. Davis, C. J. Salter, C. E. Pearson, J. Bennett Poë, W. Goldring, J. Fraser, and W. H. Williams.

Hardy flowers were the principal exhibits brought before this Committee. Messrs. Kelway & Sons, Langport, staged a splendid collection of Gladioli, comprising about 120 spikes. These, as usual, were remarkably fine and bright in colour. Two were adjudged awards of merit, and are referred to below (silver Flora medal).

Messrs. W. Cutbush & Sons, Highgate, had a large collection of hardy flowers, bright and fresh in appearance (bronze Flora medal). *Helianthus multiflorus*, *Coreopsis lanceolata*, *Chrysanthemum latifolium*, and *Geum coccineum plenum* were good in this contribution. A large number of *Liliums* and other hardy flowers shown by Messrs. Pitcher and Manda, The United States Nursery, Hextable, Swanley, also attracted attention, and a silver Banksian medal was recommended.

The *Liliums* were very fine, especially *Batemanæ* and *auratum macranthum*. Bunches of a pure white *Phlox* named The Pearl were particularly good in this exhibit. This is apparently a useful variety for cutting. A white Japanese *Chrysanthemum* named Sydenham White was shown by Messrs. Pitcher & Manda, but was passed by the Committee. Messrs. J. Veitch & Sons, Royal Exotic Nursery, Chelsea, showed a plant of *Retinospora squarrosa*, and another of *R. s. sulphurea*, both dwarf dense-growing kinds. Three baskets of *Clerodendron trichotomum*, a hardy shrub, and a number of blooms of *Bignonia grandiflora* were also shown by Messrs. Veitch & Sons. A collection of *Helianthus* from the gardens of the Royal Horticultural Society at Chiswick made a bright display. Among these *H. multiflorus* var. *plenus*, *H. m.* var. *Peter Barr* (a bright single flowered variety), and *H. m.* var. *Soleil d'Or* were exceedingly good.

Messrs. Cannell & Sons, Swanley, sent a box of *Begonia* blooms to show their adaptability for buttonholes and other decorative purposes. The varieties shown were the pink Rosebud, and Octavie, a beautiful double white. Four well grown Cockscombs were also shown by Messrs. Cannell & Sons, these being the best we have seen for some time. Mr. R. Dean, Ranelagh Road, Ealing, staged a collection of French and African Marigolds, quilled Asters, Zinnias, and other hardy flowers. A bronze Banksian medal was recommended. A box of new Cactus Dahlias was shown by Messrs. Keynes, Williams & Co., Salisbury, the blooms being fresh and bright. Several were adjudged awards of merit and are referred to below. Messrs. J. R. Pearson & Sons, Chilwell, had blooms of a new Marigold named Prince of Orange, and Mr. C. W. Allen, Floral Park, New York, staged three spikes of a *Canna* designated "Star of '91." The latter was adjudged an award of merit and is mentioned elsewhere. Some seedling *Phloxes* and Dahlias were shown by Mr. J. Farquharson, and blooms of a seedling *Begonia* were sent by Mr. W. Smythe, Basing Park Gardens, Hants. Sprays of a hybrid *Passiflora* named Woodhatch Hybrid were staged by T. B. Haywood, Esq., Woodhatch Lodge, Reigate, but did not appear to be specially noticed by the Committee. Messrs. H. Low & Co., Clapton, exhibited a group of *Lilium Wallicianum superbum*, and a silver Banksian medal was recommended. This is a very fine Lily, strongly scented, sulphur yellow in colour.

ORCHID COMMITTEE.—Present: Dr. Masters (in the chair); Messrs. Jas. O'Brien, H. M. Pollett, H. Ballantyne, W. H. White, C. Pilcher, Edward Handley, E. Hill, T. B. Haywood, and F. Sander.

Mr. S. Kerslake, gardener to the Rev. E. Handley, Bath, sent a beautifully flowered plant of *Dendrobium Phalaenopsis Schröderiana* and another of *D. P. Statteriana*. The former was in a small pan, and bore a spike carrying twenty-three flowers; the latter, a darker variety, being in a small basket, and bearing several spikes. Both merited the cultural commendations awarded. W. E. B. Farnham, Esq., Loughborough, exhibited a large and handsome group of Orchids, in which *Dendrobium Phalaenopsis Schröderiana* in several shades of colour and *D. formosum giganteum* were conspicuous. The latter was also represented by more than one shade, in some the narrow white lip being

coloured with orange, in others with pale yellow; the sepals and petals are pure white. The variety is a very attractive one, and the plants shown were remarkably healthy and vigorous specimens in 5-inch pots. A silver Flora medal was awarded.

Messrs. Sander & Co. contributed a large and very varied collection, well representing the extensive and rich stores at their command. Amongst the *Cypripediums* were *hybridum Youngianum*, *h. polystigmaticum*, *h. Mrs. G. D. Owen*, *Fournierianum*, *Maynardi*, and *Chamberlainianum*. *Odontoglossum Harryanum* was in beautiful condition. Of *Catasetum purum* there were several plants. *Cynoches chlorochilum* (the Swan Orchid) bore three growths, the largest having a spike with five of its large singular yellow flowers with green suffusion. The beautiful little *Vanda Kimballiana*, with its dark leafage and delicate flowers, was noteworthy, and there was a splendid batch of *V. Sanderiana*, figured in the *Journal* of June 23rd this year. A splendid piece of *V. coerulea* was also observable. Besides these there were *Cattleya Harrisoniæ*, *C. maxima peruviana*, *C. Gaskelliana*, *C. Schofieldiana*, *C. speciosissima*, *Angraecum articulatum*, *Dendrobium bigibbum*, *Oncidium dasystyle*, and several others. A silver-gilt Flora medal was awarded. Mr. R. Johnson, gardener to T. Statter, Esq., Stand Hall, Manchester, sent *Cattleya Amesiana*, *Lælia Turneri superbissima*, referred to below, and the Stand Hall variety of *Cattleya Schröderiana*. From Messrs. Pitcher & Manda, Hextable, Swanley, came several strong plants of *Oncidium incurvum*, bearing numerous spikes of blooms, several *Cypripediums*, such as *ænanthum*, *Arthurianum*, *grande atratum*, *tonsum*, and *Harrisianum* *Pitcherianum*, *Dendrobium Deari*, *Cattleya maxima*, *Oncidium Papilio*, *Epidendrum Brassavolæ*, and many others. A silver Banksian medal was recommended. Mr. P. McArthur, 4, Maida Vale, received a vote of thanks for a small collection, which embraced *Cypripediums* *Ashburtoniæ* and *Harrisianum*, *Cattleya Harrisonæ* and *C. Leopoldi*. Sir Trevor Lawrence, Bart., Burford Lodge, Dorking (grower, Mr. White), sent a large pan of *Miltonia Morelliana*, a form with a rosy lilac lip veined with crimson, and deep purplish maroon petals and sepals. He also sent a basket of *Habenaria militaris* a yard across, containing nearly thirty spikes of its brilliant scarlet flowers. A vote of thanks was accorded. Messrs. Hugh Low & Co. sent three freely flowered plants of *Vanda Kimballiana*, also *Cypripedium Parishii*. L'Horticulture Internationale (M.M. Linden), Brussels, contributed *Aerides Augustianum*, referred to below; *Cattleya Acklandiæ magnifica*, *C. A. zebrina*, and *C. A. superba*. All three were distinct and fine. A vote of thanks was accorded. Stanley G. Lutwyche, Esq., Oakfield, Eden Park, Beckenham (gardener, Mr. May), sent a large plant in bloom of *Peristeria elata*. Messrs. Veitch & Sons were represented by *Cypripedium H. Ballantine*, a hybrid between *C. Fairieanum* and *C. purpuratum*; *Sophro-Cattleya Veitchi*, referred to below; and *Lælio-Cattleya Proserpine*, a hybrid between *Cattleya velutina* and *Lælia pumila Dayiana*. Baron Schröder, The Dell, Egham (grower, Mr. Ballantine), sent *Phaius maculato-grandiflorus*, a hybrid between *P. maculata* and *P. grandifolius*, very striking in colour, and a vote of thanks was accorded.

In the afternoon Mr. G. Bunyard read a paper on root-pruning, a subject with which, as a cultivator of great experience, he is well qualified to deal. His paper was of a thoroughly practical character, and was listened to with much interest.

CERTIFICATES AND AWARDS.

Cattleya Oweniana (Sander & Co.).—This is a noble *Cattleya*, the flower being of imposing size, and of rich unique colouring. In general expression it reminds one of *C. gigas*, particularly in the form of the long, broad-based, somewhat flattened lip, with the narrowing side wings, which close without folding. The apical half of the lip is rich velvety crimson, the basal portion and side lobes being deeply veined with gold. It is said to be a species introduced from the *gigas* habitat, and might be regarded as a natural hybrid between that species and *C. aurea*. It resembles *C. gigas* in growth (first-class certificate).

Cattleya speciosissima var. *Sanderiana* (W. R. Lee, Esq.).—This is an extremely beautiful white form of *C. speciosissima*, resembling the species in growth and in the form of the flower; but it is of the purest white alike in petals, sepals, and lip, the only colouring being a tinge of lemon in the throat. It is a lovely flower, and evoked equal interest and admiration (first-class certificate).

Sophro-Cattleya Veitchi.—This is a remarkable hybrid obtained by crossing *Lælia* (*Lælio-Cattleya*) *elegans* variety with *Sophrontis grandiflora*. The flower strikingly shows the points of both parents, having the form of the *Lælia* with the rich colour of the *Sophrontis*, the shade being a brilliant rosy carmine, the lip deeper, inclining to magenta, and the throat tinged with yellow (first-class certificate).

Lælia Turneri superbissima (T. Statter, Esq.).—A very richly coloured form. The sepals and petals are deep rosy mauve, the lip rich, lustrous, velvety crimson (award of merit).

Aerides Augustianum (M. M. Linden, L'Horticulture Internationale).—A distinct and attractive species with long spikes of delicate pink flowers, distinct, and pure in tone (award of merit).

Dahlia Kaiserine (Keynes, Williams & Co.).—A fine bloom of the Cactus type, sulphur yellow in colour (award of merit).

Dahlia Bertha Mawley (Keynes, Williams & Co.).—This is a valuable acquisition to the Cactus class. The blooms are of medium size, good form, and bright cochineal colour (award of merit).

Dahlia Countess of Radnor (Keynes, Williams & Co.).—A Cactus Dahlia of a pinkish colour, tinged with magenta, the base of the florets being sulphur yellow (award of merit).

Dahlia Mrs. Basham (Keynes, Williams & Co.).—A neat flower of the Cactus type, and somewhat similar in colour to Countess of Radnor, already described (award of merit).

Canna Star of '91 (C. L. Allen, New York).—This is a fine variety, with bright orange-scarlet flowers of large size (award of merit).

Gladiolus Poetis (Kelway & Sons).—A light coloured variety, the edge of the flowers being tinged with pink. The lip sulphur yellow, striped with pink (award of merit).

Gladiolus Numa (Kelway & Son).—An exceedingly pretty variety. The flowers are large, light coloured, with a deep magenta edge running well into the petals (award of merit).

Pea Veitch's Success (Mr. G. Wythes).—Large scimitar-shaped pods, some containing ten peas (first-class certificate).

STRAWBERRIES AND SHEEP.

It may seem strange to utilise a flock of sheep for the removal of superfluous foliage and runners from Strawberries and to clear the ground of weeds in the autumn or at the usual time. Nevertheless this is now being done in the Strawberry fields in this neighbourhood, where many acres are under Strawberry cultivation. About three weeks since a flock of sheep was penned—not allowed to stray all over the field—on the Strawberries, with the result that in a few days not a vestige of greenery was to be seen, the sheep having nibbled every scrap of green leaf off the plants beside clearing the ground of weeds. Since then the plants have pushed forth new leaves in abundance, the field looking quite green again. The new leaves will be quite large enough to afford that protection to the crowns of the plants which is considered to be necessary for a winter coating. The plan is only another way of clearing the plants instead of mowing the whole over, as is sometimes practised with good effect by cultivators.

The land being light the treading of the soil by the sheep will do more good than harm, and by their aid manure is given to the land at the same time. Where a quantity of Strawberries are grown, as in this neighbourhood, the plan adopted is a good one, not only as a saving of labour but from a utilitarian point of view also. Certainly I never saw a Strawberry field look more promising at this season than the one in question. Had the cleaning not taken place until a month hence it might not have resulted so favourably, as sufficient time would not have been available for the maturation of the new leaves, upon which the plants are wholly dependent for their protection during the winter. Diverse opinions exist amongst Strawberry cultivators as to the wisdom of a total removal of the old leaves at the annual clearing of the plants after each crop, some holding with a total clearance, while others believe only in a partial cutting away. The present being a seasonable time for such work, perhaps others may have something to say on the subject.—E. M., *Bishops Waltham*.

NOTES ON COMPTON VERNEY.

On looking round the gardens at Compton Verney the other day Mr. Garner pointed with pride to a grand bed of Onions which was something to be proud of. A very large breadth had been devoted to this useful crop, which was as even as it well could be; the individual bulbs, too, were remarkably fine, and showed unmistakeable evidence of high culture. The variety grown is Veitch's Maincrop, which Mr. Garner considers the best for his purpose. He also attributes his success in a great measure to timely thinning when the plants are in a very young state.

The flower garden at the same place was as usual in perfect order and good keeping. The beds are just now looking at their best. In this department it was a pleasure to notice that no one style of bedding is allowed to predominate at the expense of another. Carpet beds are there, beds of Pelargoniums and Begonias, as well as others of Violas, Gladioli, and Marguerites, so that in every part there is something to attract attention beyond that seen at the first glance.

Chrysanthemums, which are largely grown for decorative purposes, both as bushes and on the single stem system, are in excellent condition, and will doubtless make a splendid show during the dull days of November.

In the vineries Madresfield Court and Black Alicante Grapes were good, the former though not large in bunch being perfectly coloured, and the latter fine in every respect; although it may seem to many somewhat early to have Alicante ripe. They are much prized for use in a few weeks' time, and when ripened thus early the flavour is decidedly better than when the ripening is not completed till the end of September.—H. DUNKIN.

ROELLA CILIATA.

THIS plant is a member of a small genus belonging to the Campanulaceæ, the chief characteristic being derived from the capsule,

which is elongated and two-celled, opening by a hole in the apex. The species shown in the engraving (fig. 30) is a beautiful but somewhat delicate plant, and requires care and attention to grow it satisfactorily. It is well deserving the attention of all plant-growers. Pot in good fibry peat, adding about a third of sand, and if some pieces of sandstone or charcoal are introduced they will serve to keep the soil more open and greatly benefit the plant. Special care must be given to the drainage, not so much as regards quantity as in the matter of covering, in order to prevent the soil running into it and stopping the free percolation of the water; for although the plants enjoy a liberal supply of water, they cannot suffer the slightest stagnation, for when this comes about, either at the roots or in the atmosphere, its greatest bane, mildew, is sure to make its appearance. By no means stimulate the plants

FIG. 30.—ROELLA CILIATA.

during winter, but have the growths well ripened in autumn, and the plants will pass through the dull season in good condition. The growths made in winter are always weak and miserable. A dry atmosphere with a free circulation of air is requisite for the health of the plants and the prevention of mildew.

Roella ciliata is a slender-growing, much-branched, greenhouse shrub, attaining a height of some 2 or 3 feet. Leaves Heath-like and light green. There are five distinct colours in the flowers, which, being disposed in rings or circles, produce a striking effect. The base of the corolla is yellowish white; succeeding this is a circle of deep bluish black; above this comes another circle of lavender blue succeeded by a narrow ring of white, whilst the spreading lobes are pale purple.

It blooms during May, June, and July, and is a native of the Cape of Good Hope.

EVENTS OF THE WEEK.—One or two of the Shows which commenced on Wednesday are continued to-day (September 8th); for instance, that of the National Chrysanthemum Society at the Royal Aquarium, Westminster, and that of the Royal Caledonian Horticultural Society, Edinburgh. Shows will also be held to-day at Paisley and Thame. On Friday, September 9th, an Exhibition of autumn flowers opens at the International Horticultural Exhibition, and will be continued on the following day. On Saturday, September 10th, there will be a Show of early Chrysanthemums and Dahlias at Leicester. On Wednesday, September 14th, the Kelso Horticultural Society's Show will be held. Several auction sales will be conducted by Messrs. Protheroe & Morris, of which particulars are given in the advertisements.

— **THE WEATHER IN LONDON.**—Colder weather has been experienced since our last note was written, although dry on the whole. On the 4th a strong wind prevailed, and the weather, though bright, was very cold. The 5th opened cold and somewhat foggy, but bright sunshine later on rendered the surroundings warmer and clearer. On the 6th the same conditions prevailed. At the time of going to press the wind is westerly, the glass somewhat depressed, and rain threatening.

— **ROCK PLANTS AT CHISWICK.**—The Royal Gardens, Kew, have made a munificent donation to the Royal Horticultural Society of upwards of 200 named plants for the rockery at Chiswick. Now that the public taste has set in in this direction this gift is particularly acceptable.

— **PEACHES AND NECTARINES AT CHISWICK.**—The outdoor Peaches and Nectarines in the Royal Horticultural Society's Gardens at Chiswick are now a splendid sight. The trees are trained to a south wall, and amongst the varieties carrying good crops are Frogmore Golden, Stirling Castle, Salwey, Violette Hâtive (particularly fine), Goshawk, Gregory's Late, Early Louise, and Prince of Wales.

— **APPLE BARCHARD'S SEEDLING.**—This comparatively little-grown Apple is well worthy of an extended trial. In a large Kentish orchard some young trees promise remarkably well, for the variety comes into bearing very early, and gives good crops of handsome fruit. Some trees at Chiswick are carrying a heavy crop of the conical fruits, which are deeply flushed with crimson. It appears to bear the most freely towards the tips of young shoots, and close spurring should therefore be avoided.—P.

— **TELEKIA SPECIOSISSIMA.**—This fine perennial, sometimes known under the name of Bupthalmum, will succeed equally as well in the open border as it will in the shade, providing it has plenty of space and fairly good soil, indeed that is a necessity to bring out the true characteristics of both foliage and flowers. This hardy plant is a suitable object for growing on grass in an isolated position where the beauty of its bold foliage is seen, and it can have space to develop fully.—E. M.

— **STEPHANOTIS FRUITING.**—I have at present a fruit of Stephanotis which first showed itself twelve months ago last July, and is now ripe. It measures in length, from stalk to point, 5 inches, and is 7½ inches in circumference at the thickest part; it is exactly the shape of an egg. Is it not rather an unusual size? I have shown it to several gardeners, but some have never seen a fruit before, and others only very small ones. Perhaps some of your readers may be able to enlighten us with regard to it.—C. E.

— **DUNDEE FLOWER SHOW.**—The Dundee Horticultural Society's Show at Magdalen Green opened under favourable conditions. Throughout the day it was largely patronised. In the forenoon, owing to the unsettled nature of the weather—which was showery, gusty, and cold—the visitors were comparatively few in number; but in the afternoon, when the atmospheric conditions had hardened somewhat, the enclosure rapidly filled up. The throng, however, reached its largest dimensions in the evening. The Exhibition was an excellent one in every way.

— **EDUCATION IN GARDENING.**—For essays on the above subject one of the silver medals of the *Journal of Horticulture* has been adjudged to Mr. Thomas Garnet, St. John's, Wakefield, and one to Mr. E. D. Smith, Walkley, Sheffield. These essays will be published in our columns in due time.

— **DOUBLE ZINNIAS.**—Mr. Turton of Maiden Erleigh showed at Reading one of the finest formed lots of double Zinnia flowers I have seen. The blooms were not only of perfect form, but were very large. I saw the plants from which these flowers were gathered the following day growing on a south border in the kitchen garden at Maiden Erleigh. There were several hundreds of plants from Messrs. Sutton & Sons' strain; not one had single or inferior blooms, and in variety and colouring they were wondrously beautiful. Mr. Turton plants out after early Potatoes from small pots. He finds the finest blooms come from crown flowers as a rule, but the side branches also give good ones.—A. D.

— **BARON SCHRÖDER'S BARONETCY.**—We are for once glad—in fact very much delighted—in having been led from the line of strict accuracy. We had a paragraph in type announcing the well-merited honour conferred by Her Majesty on the great patron of horticulture, Baron Schröder of Egham, but it was withdrawn in consequence of information received from a source which we could not treat otherwise than reliable; and the same information was presumably supplied to at least one of our contemporaries, which made no comment on the subject. We have authority for stating that the popular Baron, as the head of his family, must retain his German title, and he will be known, as heretofore, as Baron Schröder.

— **THE SHREWSBURY HORTICULTURAL FÊTE.**—Phenomenal success attended the August Exhibition, the revenue from all sources amounting to the great sum of £3700 for a two-days Exhibition. The weather was good on the first day, threatening until past mid-day on the second, then clearing off to fine, and 40,000 persons paid at the gates. With the holders of about £700 worth of tickets previously, and subscribers and assistants, not less than 53,000 persons were present on the second day. There was no hitch, and all went well. The judging was done in good time, and the arrangements were good; but Messrs. Adnitt and Naunton, the Hon. Secretaries, with their eighteen years' experience, know how to manage these big shows.

— **FLOWER SHOW TROUBLES.**—We had the pleasure of seeing the wonderful Black Country Show at Bilston, near Wolverhampton, last year, for wonderful it is, and we are informed that this year the record was beaten by a display of very superior excellence all round. The Judges, six in number, who always act there, unanimously declaring it to be the best in quality of the twelve which have been held. But troubles of a very serious character awaited the Committee during the night of the opening day, for a severe thunderstorm with such an accompaniment of lightning as we rarely see, followed by a terrific gale, blew down one large tent and played sad havoc with the exhibits, and one side of another very large tent was blown in and the exhibits sadly injured. A few days after, at a large Exhibition at the Moseley Botanic Gardens, Birmingham, a fierce and protracted gale tried hard to blow down a large tent 250 feet long, and but for extra strong ropes, tent pegs, and watching night and day it would have gone, but fortunately no damage was done.

— **DESTRUCTION OF INSECTS BY OIL.**—Insects generally breathe through special pores in various parts of their body, and if these pores are closed by oil they are suffocated. Anyone may test this by dropping sweet oil on the thorax or back of a wasp; it very soon dies. For this reason oil has been found one of the best things to use for the destruction of insects. Unfortunately it is difficult to spread it properly over plants. At one time oil was spread on with water, and the syringe made to draw up a little water and oil together as the syringe was taken from the vessel containing the liquid, but this has never had a great deal of practical value. It is not generally known, at least it was left to a correspondent of the "Gardeners' Monthly," Mr. A. D. Brown of Princeton, N.J., several years ago to show that by the use of chalk or soap, or other substances, oil and water could be made to amalgamate, and in this way make a safe and effectual wash, although it still has to be stirred up continually while being applied. A wineglassful of oil to a gallon of hot water, with about one-half a glassful of soft soap mixed together, will make a wash of this kind. There is nothing better than this for scale on Lemon trees, Oleanders, and indeed, by the aid of a fine syringe, on almost any insect-infested plant.—("Meehan's Monthly.")

— LEIGHTON BUZZARD FLOWER SHOW.—For once the Committee of the Leighton Horticultural Society succeeded in fixing upon a fine day for their annual Show, and as a consequence there was a good attendance during the afternoon. The Show was above the average, splendid exhibits being contributed by Mr. Cypher, Mr. Finch, and Mr. Walker of Thame.

— A GIANT CACTUS.—An effort is being made to secure for exhibition in the Horticultural Department of the World's Fair a specimen of giant Cactus from the desert region of south-east California. This Cactus grows at times to the height of 70 feet. A specimen when boxed ready for shipment will weigh 8 tons, and it will require an expenditure of something like £500 to deliver it in good condition in Chicago.

— PRUNUS PISSARDI FRUITING.—We send you by this post fruits of *Prunus Pissardi*, which we shall be glad if you will notice in your widely read paper. We believe it is rare for the fruit to be produced in this country.—E. D. SHUTTLEWORTH & Co. (LTD.), *Fleet, Hants*. [As the trees attain the requisite age they bear fruit under favourable conditions in this country, the same as the *Myrobalan* or *Cherry Plum* does, of which *Prunus Pissardi* is a purple-leaved variety.]

— AUGUST WEATHER IN HERTS.—The weather during the past month has been particularly cool. Only during three days has the thermometer risen above 75° in the shade, and not once has it reached 80°. There has also been a fair amount of sunshine, and more than the usual amount of rain. Rain fell on eleven days during the past month. The maximum in any twenty-four hours was 1.33, registered on the morning of the 28th. The minimum in any twenty-four hours was 0.03 on the 8th. The total during the month was 3.40, against 3.58 of 1891.—E. WALLIS, *The Gardens, Hamels Park, Buntingford, Herts*.

— THE WEATHER DURING AUGUST AT RIPLEY, YORKS.—The weather this month was fairly favourable. From the 19th to the 24th we had some of the most summer-like weather of the season, but the nights during the whole of the month were very cold. The total rainfall was 3.21 inches, which fell upon eighteen days, the greatest fall being 0.94 on the 29th. The mean reading of the barometer for August was 29.93. Mean maximum temperature, 67.4°; mean minimum temperature, 43.6°; mean temperature of the month, 55.5°. Highest maximum temperature, 78° on the 21st; lowest minimum temperature, 34° on the 11th. Up to the present we have not lifted one diseased Potato.—J. TUNNINGTON, *Ripley Castle Gardens, Yorks*.

— THE WEATHER LAST MONTH.—August was very changeable; we had a heavy thunder storm early on the 24th, and gales on the 14th, 30th, and 31st. The wind was in a westerly direction twenty-three days. The barometer was highest (30.29 inches) at 9 A.M. on the 10th; lowest (29.49) at 9 P.M. on the 30th. The total rainfall was 1.52 inch, which fell on fourteen days; the greatest daily fall being 0.37 inch on the 27th. The highest shade temperature was 81° on the 23rd, the lowest 35° on the 11th; the lowest on grass 35° on the 11th. Mean of daily maximum readings 70.53°; mean of daily minimum readings 50.96°. Mean temperature of the month 60.74°. The garden spring ran 20 gallons per minute on the 31st.—W. H. DIVERS, *Ketton Hall Gardens, Stamford*.

— SULPHATE OF COPPER FOR SCAB.—Dr. Fisher, one of the experimenters at the Hatch Experiment Station, has, says an American paper, laid us under a debt of gratitude if his views are well grounded. He believes copper sulphate in simple solution to be just as effective in destroying injurious fungi as any other preparation of copper. Moreover, it is much less expensive; the amount required being only 1 lb. to 600 or 800 gallons of water, while the Bordeaux mixture requires 4 lbs. for 50 gallons of water; counting the copper sulphate at 4d. a pound, this is 1s. 4d. per barrelful, which amounts to a considerable sum in a large orchard. His plan of operation is as follows:—As early in spring as weather permits gather and burn all stubble, weeds, grass, and *débris*, thus disposing of a large proportion of the winter spores of the various fungi. Then spray all trees, trellises, and Vines, and the surface of the ground not burned over with sulphate of copper—1 lb. to 100 gallons. This strength is only allowable before the foliage has developed. Just before the blossoms open spray all foliage with the solution, 1 lb. to 800 gallons, adding Paris green 1 lb. to 200 gallons. This should be repeated two or three times in the month of June, when the great bulk of both insects and fungi appear. Those who try this should do so on a small scale and note the results.

— HYDRANGEAS AND GLADIOLI.—We ("Garden and Forest") observe in some florists' windows a repetition of the practice which prevailed three or four years ago, of using the large white flower-heads of *Hydrangea paniculata grandiflora* on long stems, in large vases, with a few spikes of *Gladiolus* of some pronounced colour. This makes an effective combination, as well as a very durable one, for the *Gladiolus* will continue to open its flowers in succession for a long time, and the *Hydrangea* flowers will not only remain without wilting for a fortnight in a warm room, but will dry on the stem and preserve their creamy colour throughout the winter.

— AN ENORMOUS STRAWBERRY.—This fruit was sent to me a few weeks since, and deserves to be placed on record in your pages. Its circumference was 10 inches, the greatest diameter 2 $\frac{3}{4}$ inches; the weight rather more than 3 ozs. The variety was Laxton's Competitor, a strong-growing kind, but the fruits which I have tasted of it have all been deficient in flavour. The above fruit was very flat. It was grown by Mr. R. Gilbert, Burghley Gardens, Stamford, and was certainly the largest Strawberry I have ever met with.—W. H. DIVERS, *Ketton Hall Gardens, Stamford*.

— FUCHSIA FULGENS.—This old plant is seldom cultivated, and yet it is well worthy of a place in every large garden. The stems are red, the leaves cordate, soft and glabrous, with a red petiole, and prominent red veins. The flowers have a bright red calyx, forming a long narrow tube; the petals protrude beyond the divisions of the calyx, and are bright scarlet. The racemes are long and pendulous, terminal, and many-flowered. Plants grow very quickly when planted out, and form bushes 2 to 3 feet high. A bed at Chiswick is looking very well at present, but the pale green leaves do not show off the flowers as well as darker ones would. This is its only drawback.—C. K.

— MARKET TOMATOES.—The estimate of what is a good market Tomato differs appreciably. Some growers seem to think they cannot be too big, whilst salesmen seem to think the reverse. When at Heckfield Place, on the 1st, Mr. Maxim, the gardener there, invited me to look at a red Cluster Tomato, a few plants of which he has sent for trial by Messrs. Sutton & Sons. The fruits were of perfectly round form, running at about ten or twelve to the pound, and are borne in great clusters. The gardener said, "The other day Mr. ———," naming a well-known London salesman, "sent me a couple of small Tomatoes, saying that those were of the sort he wanted to please his customers, who wanted them small and in plenty." Mr. Maxim regards this new variety of Messrs. Sutton to be thus a *beau idéal* market Tomato.—A. D.

— ROMNEYA COULTERI.—Having been very successful in raising and flowering plants from seed of the grand Californian Poppy, *Romneya Coulteri*, we thought perhaps you would like to see a spray cut from one of our plants growing in a pot with the shelter of a cool greenhouse to protect the flowers from storms, and by this post we send you specimens. You must not, however, infer from this that greenhouse protection is absolutely necessary, as we have plants which have been growing outside during the last three winters, and at the present time look remarkably healthy, but we do not think they will flower at present, as the season generally in the Birmingham district has been cold and sunless.—R. H. VERTEGANS & Co. [A beautiful spray of this magnificent plant, which was illustrated in the *Journal* on February 7th, 1889.]

— A GARDENERS' OUTING.—About forty members of the Winchester and District Gardeners' Mutual Improvement Association took part in the first annual outing organised by this Society, which has been in existence about thirteen months, and paid a visit to Reading, on the date of the Reading Show, on August 31st. The party were met at the station by a representative of Messrs. Sutton & Sons, by whom they were conducted over the business premises of this well-known firm, in the Market Place. On leaving the seed stores brakes were waiting to convey the visitors to the trial farm, where many things of interest were examined. From there they were conveyed to the nursery, and spent an agreeable hour and a half among the various objects of interest. Special mention may be made of the Begonias, Gloxinias, Cyclamens, and Tomatoes. The party then returned to the Market Place, where they were entertained to lunch by Messrs. Sutton & Son. The party then divided—some going to the flower show, others visiting the biscuit factory, and other places of interest in the town. The party returned to Winchester by train early in the evening, after a most enjoyable and instructive day.

— **PLUMBAGO CAPENSIS.**—Gardeners usually look upon this as a greenhouse or stove plant, and consequently treat it as such; under these conditions it succeeds very well. Few treat it as a summer bedding plant; but it is wonderful how well it succeeds planted out in the Royal Horticultural Society's gardens at Chiswick. Planted at the same time as other bedding stuff the plants commence at once to grow vigorously, and soon fill the bed with young growths, each of which will bear a terminal spike of pale blue flowers about the beginning of September. *P. capensis* was introduced from the Cape of Good Hope in 1818; it is readily propagated, and after flowering in the beds the plants should be taken up, cut hard back and potted, keeping them rather dry during the winter. If repotted in spring and kept hardy the plants will be useful for several seasons. When planted out *P. capensis* grows about 2 feet high.—C. K.

— **SUMMARY OF METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, WORKSOP, NOTTS, IN AUGUST;** 56 feet above the mean sea level.—Mean temperature of the month, 58.9°. Maximum on the 23rd, 78.2°; minimum on the 11th, 39.2°. Maximum in sun on the 22nd, 132°; minimum on grass on the 11th, 32.1°. Mean temperature of the air at 9 A.M., 60.6°; mean temperature of the soil, 1 foot deep, 58.6°. Total duration of sunshine in the month, 130 hours, or 29 per cent. of possible duration; we had two sunless days. Total rainfall, 1.79 inch. Maximum fall in twenty-four hours on the 29th, 0.85 inch; rain fell on eleven days. Wind, average velocity, 8.6 miles per hour; velocity exceeded 400 miles on two days; fell short of 100 miles on eight days. Approximate averages for August:—Mean temperature, 59.7°. Sunshine, 149 hours. Rainfall, 2.36 inches. A cool and rather cloudy month, but with very little rain up to the last three days.—J. MALLENDER.

— **FLOWER SHOW AT ILKESTON.**—On Saturday last the annual Exhibition of vegetables, fruit, and flowers in connection with the Shipley and Cotmanhay Floral and Horticultural Society was held at Ash Street, Ilkeston, and was well attended. The produce shown was declared by the Judges to be the finest displayed in Ilkeston for many years, and the equal merit of most of the exhibits, particularly in the vegetable classes, was very noticeable. Mr. J. Webster had grand kidney Potatoes, Messrs. T. Winfield and T. Neath showing the premier "rounds." The other first prizetakers in vegetables were Messrs. A. Cockayne, T. Hallam, R. Cook, J. Cook, sen., W. Norman, W. Wheatley, J. Taylor, A. Stirland, and W. Whitehead. In fruits the premier prizes fell to Messrs. W. Whitehead, J. Cook, sen., W. Norman, E. Roe, A. Stirland, and A. Cockayne; and in flowers, plants, &c., to Messrs. J. Wheatley, E. Roe, W. Norman, J. Cook, sen., A. Stirland, W. Wheatley, J. Webster, S. Calladine, W. Whitehead, and W. Small & Sons.

— **ASTERS FOR INDOOR DECORATION.**—Just at the present time the various types of these handsome flowers are particularly useful for the purpose above indicated. We use them freely in window boxes, jardinettes, large vases, and bowls, in which they make a good show, and are a welcome change from the class of plants employed for some weeks previously, such as Marguerites, Celosias, Pelargoniums, and Begonias. The dwarf types are especially prized when arranged alternately with *Panicum variegatum* or other striped Grasses, and dotted with Palms, Acacias, or Celosias the effect is very striking. Asters lift so well that it is not necessary to place them in pots till the flower buds are formed. If they are then potted and placed in a shady position they quickly establish themselves, and are in a few weeks ready for use. Dwarf Chrysanthemum-flowered and Victoria are capital varieties for the purpose. Daniels' Dwarf Perfection is also excellent, and produces very large flowers for a dwarf sort.—H. D.

— **WATER PLANTS IN JAPANESE GARDENS.**—From Mr. Lafcadio Hearn's article, called "In a Japanese Garden," published in the July number of the "Atlantic Monthly," we quote the following:—"The garden contains no large growths. It is paved with blue pebbles, and its centre is occupied by a pondlet, a miniature lake fringed with rare plants, and containing a tiny island. Here and there at the edge of the pond, and almost level with the water, are placed large flat stones, on which one may either stand or squat, to watch the lacustrine population or to tend the waterplants. There are beautiful Water Lilies, of which the bright green leaf-disks float oilily upon the surface (*Nuphar japonica*), and many Lotus plants of two kinds, those which bear pink and those which bear pure white flowers. There are Iris plants growing along the bank, of which the blossoms are prismatic violet, and there are various ornamental Grasses and Ferns and Mosses. But the pond is

essentially a Lotus pond; the Lotus plants make its greatest charm. It is a delight to watch every phase of their marvellous growth, from the first unrolling of the leaf to the fall of the last flower. On rainy days especially the Lotus plants are worth observing. Their great cup-shaped leaves, swaying high above the pond, catch the rain and hold it awhile; but always after the water in the leaf reaches a certain level the stem bends, and empties the leaf with a loud splash, and then straightens again. Rain water upon a Lotus leaf is a favourite subject with Japanese metal-workers, and metal-work only can reproduce the effect, for the motion and colour of water moving upon the green oleaginous surface are exactly those of quicksilver."

— **FLOWERS OF THE INDIARUBBER.**—A correspondent sends us ("Meehan's Monthly") some buds taken from the axils of the leaves of an Indiarubber, which he took to be an abortive flower bud; but which, on being cut open, appeared more like the immature Fig. This is all right, because the plant usually known as Indiarubber is really a Fig—that is to say *Ficus elastica*. These little buds frequently appear in Indiarubber plants; but we have not known them to perfect themselves in our country. We should be glad to know whether this does occur at times under cultivation. An examination of these buds is very interesting to those who would understand the structure of the Fig. We may say in common language, that the Fig is a bunch of flowers turned inside out. The flowers of the Fig are all on the inside of this bud—some of them are purely staminate and others pistillate. It is a frequent subject of controversy whether the common garden Fig has fruit wholly of one kind or wholly of the other kind. We are quite sure, notwithstanding the opinion of some botanists, that we have found both the barren and fertile flowers in the same Fig; and this will be found occasionally in the fruit of *Ficus elastica*. When examined with the lens, these little flowers inside the Fig will be found very beautiful and well worthy of study.

— **SEAKALE FROM CUTTINGS.**—Although this may not be quite a seasonable time to talk about Seakale from root cuttings, I am led to the subject by the closing note of the report of Oakley Hall Gardens, page 191, where "A. D." says, "Curiously enough Seakale from root cuttings is first class." From this remark I can only conclude that in "A. D.'s" experience this method of growing Seakale is a novelty. I may be wrong, but from the wording I can infer nothing else. If he saw the quantities grown in this neighbourhood for market purposes he would cease to think it curious. It would be difficult to find better examples, and all grown from root cuttings inserted in the early part of the current year. By the beginning of next March they will all have been cleared off and forced. Seakale is considered to be one of the best paying vegetable crops in these parts, the soil apparently suiting its requirements to a nicety. The method adopted is to collect all spare pieces of roots 4 inches long when digging them up for forcing, commencing early in the autumn. The roots are cut into the lengths named, tied in bundles, and covered over with soil, where they remain until it can be seen which end of each root promises the best growth; the pieces are then ready for planting in rows in the open, the tops of each piece being just covered with soil. The land is well prepared by manuring freely, which induces a free growth, and by the autumn splendid crowns are available.—SOUTH HANTS.

NEW VARIEGATED FERNS.

THE three new variegated Ferns exhibited by Mr. H. B. May at Chiswick on August the 23rd and 24th, and for which first-class certificates were awarded by the Royal Horticultural Society, are valuable additions to our greenhouse Ferns. They were all raised from the same batch of seedlings, and a curious point is that several plants of each variety were obtained. They all came from a batch of seedlings of *Pteris Victoriae*, which consisted of several hundreds of the true type.

Of the three distinct varieties the most remarkable is *Pteris tremula variegata*. This has the true character of tremula; the pinnae are perhaps a little narrower than the variety of tremula now mostly grown, but exactly the same form exists among green varieties of tremula. The variegation consists of a silvery grey linear marking, which also runs through in stripes nearly to the margin of the pinnules. As Mr. May already has several plants of the same variety there is every reason to hope that there will be little difficulty in getting it true to character from spores, and if so it is sure to become one of the most popular Ferns for decoration.

P. reginae partakes more of the habit of *P. Victoriae*, but is of more

vigorous growth. The variegation consists of a linear band of silvery white, radiating in stripes which run through to the margin of the

of *P. Victoriae* were much inclined to produce imperfect fronds, but as the plants have advanced they have grown out of that imperfection to a

FIG. 31.—PTERIS REGINA CRISTATA.

pinnae. *P. reginae cristata* is a very prettily crested variety, hence very distinct. It is represented by fig. 31.

The plants exhibited were raised from spores sown about a year ago. They have been grown in a moderate stove temperature. The seedlings

great extent, and Mr. May now has a good batch of well developed plants. Being of slender growth it requires more care than many of the *Pterises*; for one thing, overpotting should be avoided, also excess of moisture.

HORTICULTURAL SHOWS.

BATH.

ONCE more the Committee of the Bath Floral Fêtes have met with a serious disappointment, one of the best exhibitions they have ever had being completely marred by the wretchedly bad weather experienced on the opening day. The attendance was good on the second day, but the deficit on the whole undertaking must be very heavy, and this is much to be regretted, the finances already being in a poor plight owing to a series of bad days having taken place.

Fuchsias invariably occupy the most prominent position on the prize list and in the show tent, and these, though very well shown, were scarcely so good as usual. The best nine specimens were shown by the veteran grower and raiser, Mr. J. Lye, gardener to the Hon. Mrs. Hay, who had tall, neat, and beautifully flowered pyramids of Charming, Abundance, Annie Earle, Duchess of Fife, Lye's Rival, Doel's Favourite, Miss Balfour, Mrs. Rundle, and Final. Mr. G. Snell, gardener to Mrs. Counsell, Bath, staged much larger specimens, but not so well flowered as Mr. Lye's, and was placed second, Mr. J. H. Willcox being third with dwarf, very well flowered pyramids. For six specimens Mr. W. Marchant, gardener to Jerome Murch, Esq., Bath, was easily first, showing Final, Arabella, Doel's Favourite, Bountiful, Lye's Favourite, and Charming in good condition. Mr. A. F. Cray, Frome, was a creditable second. The principal prizewinners in the other classes for Fuchsias were Messrs. Marsh, Doherty, Lye, Snell, and Marchant, the exhibits being highly creditable in each instance.

With stove and greenhouse plants Mr. J. Cypher, Cheltenham, was well to the front, taking first prizes in numerous classes with his well known specimens; Messrs. Heath & Son, Cheltenham, and Mr. J. Curry, Salisbury, following in the order named in the class for eighteen plants. The first prize for six flowering plants was well won by Mr. McBennett, gardener to C. W. Mackillop, Esq., Bath, who had *Ixora Regina*, *Bougainvillea glabra*, *Dipladenia Brearleyana*, *Allamanda nobilis*, *Ixora Pilgrimi*, and *Clerodendron Balfourianum* in good condition. Mr. G. Tucker, gardener to Major Clarke, Trowbridge, was a close second.

Orchids were not extensively shown. The best six, these consisting of *Cattleya aurea*, *Odontoglossum grande*, *Vanda cœrulea*, *Odontoglossum Harryana*, *Dendrobium Phalaenopsis Schröderiana*, and *Cypripedium Harrissianum*, were staged by Mr. Cypher, the second prize going to Mr. R. B. Cater. Zonal Pelargoniums were well shown, though Mr. G. Tucker was easily first for six varieties, the second prize going to F. J. Tate, gardener to W. Pumphrey, Esq., Bath; and the third to Mr. E. Hall, Bath. With four varieties Mr. W. Marchant was first, and R. B. Cater, Esq., second; while for Ivy-leaf varieties Mr. W. J. Stokes was first, and Mr. A. Cray second. Gloxinias were fairly numerous and good, Mr. Tucker having the best, Mr. J. A. Timmins also showing well. Three classes were provided for Liliums, all being well filled. The principal prizewinners were Messrs. Cole & Son, W. Marchant, T. Carr, and E. A. Jones. Messrs. Cooling & Son were first for very fine Cockscombs, a little overpotted perhaps, the second prize going to Mr. R. B. Cater. Tuberosus Begonias were very good, notably those which gained Mr. J. B. Blackmore the first prize in the classes for both single and double flowering varieties; Mr. F. Mead, gardener to J. Stuckey, Esq., and Mr. J. A. Timmins also showing well, and taking prizes. Ferns were in admirable condition. The first prize for twelve exotic specimens went to Mr. J. Deacon, gardener to H. J. Harris, Esq., Calne; the second to Mr. G. Tucker; and the third to Mr. E. Daggar, gardener to Mrs. Simms. The best British Ferns were shown by Messrs. Cole & Sons, Brown & Son, Frome, being a very close second. Coleus were considerably above the average, notably those which gained Mr. McBennett the first prize and the second prize lot staged by Mr. J. Lye.

There were four competitors in the class for groups arranged for effect on a space not less than 100 square feet; but although all made very creditable displays, the old stiff greenhouse arrangements that used to prevail at Bath being departed from in each instance, the Judges had no difficulty in awarding Mr. J. Cypher the first prize. The premier prize group was generally considered the most effective ever seen at Bath, and was one of the principal features in a generally excellent show. The background was sufficiently heavy and imposing to form an admirable foil for a series of charming isolated groups composed of central elegant Palms with a base of choice Orchids and Ferns in the foreground. The intervening spaces were mossed over, and were relieved by a few choice yet showy plants at wide intervals or in conspicuous positions. Mr. J. Deacon took the second prize with an arrangement consisting principally of a groundwork of Maidenhair Fern with numerous well grown Palms, *Dracenas*, *Crotons*, Orchids, Cockscombs, and other plants dotted at rather too regular intervals among them. Mr. McBennett had a somewhat similar arrangement, but the materials were scarcely so good, and was third; while an extra prize went to Mr. J. Curry, who displayed more taste and originality than either Mr. Deacon or Mr. Bennett, but his plants were not sufficiently fresh to please the Judges.

Cut flowers were most extensively shown, several fine stands being unavoidably passed over, more especially where there was no limit to the number of bunches, in favour of those comprising the greater number of varieties—a state of affairs that several persons thought ought to be prevented another year. Gladioli were surprisingly good, notably the grand stand of thirty-six spikes, as shown by W. H. Fowler, Esq., Taunton. Mr. S. Bird, gardener to F. H. Fox, Esq., was a very creditable second in this class; and Mr. A. A. Walters, Bath, a close third. For twelve varieties Mr. S. Tottle, Taunton, was first; Mr. J. Nation,

also of Taunton, second; and Messrs. Cole & Son third. The best twenty-four Dahlias were shown by Mr. G. Humphries, Chippenham, included among these being grand blooms of Mrs. Davis Saunders, Henry Walton, Maud Fellowes, W. Rawlings, Reliance, John Walker (a fine white), and Mrs. Humphries (pearl-pink, a distinct improvement on Mr. G. Rawlings). Mr. J. Nation was a good second; and Mr. F. Harris third. For twelve varieties Mr. T. Hobbs, Bristol, was well first; Mr. J. Newman being second, and Mr. T. Haskins third. The first prize for twelve Fancies went to Mr. G. Humphries, among these being perfect blooms of Mrs. J. Downie, J. Cooper, Mrs. Saunders, and Salamander. Mr. J. Nation was second; and Mr. W. Smith third. With single Dahlias Mr. A. A. Walters was well first; Mr. T. Carr being second; and Mr. T. A. Vickless third. A grand box of new Cactus Dahlias, shown by Messrs. Keynes, Williams & Co., Salisbury, received very high commendation from both the Judges and visitors. The varieties were Kynereith, St. Catherine, Baron Schröder, Lady Skelmersdale, Bertha Mawley, Countess of Radnor, Apollo, and Countess of Gosford. Roses were fairly numerous and good, Bath amateurs, however, having matters very much their own way. For twenty-four single blooms, distinct, Dr. Budd was well first, some of his best being François Michelin, Captain Christy, Camille Bernardin, Souvenir de la Malmaison, A. K. Williams, Alfred Colomb, Marie Rady, Marie Margot, and C. Lefebvre. Mr. A. Hill Gray was a creditable second. Similar positions were occupied by these growers in the class for twelve varieties, but for a like number of Teas Mr. Gray succeeded in turning the tables on his formidable rival. His blooms of *Maréchal Niel*, *Souvenir d'Elise Varden*, *Madame Lambard*, *Madame C. Kuster*, *Madame Camille de Rohan*, *Alba rosea*, and *Comtesse de Nadaillac* being particularly good. A certificate of merit was awarded to Messrs. G. Cooling & Sons, Bath, for a grand display of Teas in bunches, four boxes of these being staged. Verbenas, Asters, Pelargoniums, and Hollyhocks were all numerous and well shown; the principal prizewinners being Messrs. G. Garraway, W. F. Catlin, W. J. Jones, A. A. Walters, R. B. Cater, G. Tucker, E. Hall, J. Burgess, and W. Smith. Five competed with twenty-four bunches of stove and greenhouse flowers, distinct, and a very beautiful display they made. Messrs. E. Cole & Sons were first, H. Pocock second, G. Tucker third, and H. C. F. Applegate highly commended. Messrs. Cooling & Sons had a grand lot of hardy herbaceous flowers in bunches, all the best species and varieties in cultivation being represented, and were rightly awarded the first prize; Mr. A. A. Walters following with a remarkably well set up collection. Mr. G. Garraway was third, and there were six other lots shown. Annuals in bunches were also numerous shown, the first prize going to Mr. F. Hooper, Bath; the second to Mr. A. H. Newman; and the third to Mr. J. Stuckley. Mr. Cypher was well first for a vase; Mr. E. S. Cole being second, and Mr. T. Meakins third; while for a hand bouquet the prizes went to Mr. F. Case, Cardiff; C. Dobson, Clifton; and Brown and Son in the order named.

The fruit tent is always very popular at this Show, and was even better than usual. Some idea of the extent of the display will be gathered from the fact that upwards of 250 bunches of Grapes were shown, there being enough of these to extend completely round a fairly large tent. Four competitors staged a collection of twelve dishes of fruit, but Mr. W. Nash, gardener to the Duke of Beaufort, Badminton, was easily first, having excellent Alicante and well-coloured Muscat of Alexandria Grapes, Golden Gem and Hero of Lockinge Melons, *Violette Hâtive* and *Stirling Castle* Peaches, Rivers' Orange and Galapin Nectarines, Morello Cherries, Hemskerk Apricots, Prince of Wales Plum, and Williams' Bon Chrétien Pears, all in perfect condition, the good colour throughout being very marked. Mr. J. Cray was a good second, and Mr. Pymm, gardener to Mrs. Goldsmith, Trowbridge, third, the Grapes in this case being somewhat poor.

Five competed with a collection of eight bunches of Grapes in four varieties, but Mr. W. Taylor, gardener to Alderman Chaffin, Bath, was well first, having grandly finished clusters of Muscat of Alexandria, Alicante, Alnwick Seedling, and Madresfield Court. Mr. J. Gibson, gardener to Earl Cowley, Chippenham, was a highly creditable second; and Mr. J. Bury, gardener to C. Bayer, Esq., London, a good third. No less than eighteen growers competed with three bunches of Black Hamburg, the first prize for which went to Mr. J. Gibson, who had fine, well-finished bunches; Mr. J. Marshall, gardener to J. Dole, Esq., being a good second; and Mr. W. Robinson, gardener to Lord Justice Lopes, Westbury, a close third. Fifteen competed in the class for any other black variety, and here Mr. W. Taylor was a good first with Madresfield Court in perfect condition; Mr. W. Nash being second with very fine Alicante; and Mr. S. Bryant, gardener to Dr. Grace, Kingswood, third with very good Muscat Hamburg. Nine staged Muscat of Alexandria, but Mr. W. Taylor was easily first with fine, well-coloured bunches; Mr. P. Davidson, gardener to Lord Wolverton, Shaftesbury, being second; and Mr. T. Wilkins, gardener to Lady Theodore Guest, Blandford, third, the bunches being well finished in both instances. In the class for any other white variety ten competed. Mr. J. Marshall was first with grand Buckland Sweetwater; Mr. Wilkins being second with Foster's Seedling, in better condition than is often seen; and Mr. W. Trevillian third with good Buckland Sweetwater. A local class for Grapes also attracted good competition, several growers exhibiting very creditably. Mr. Marchant was first with good Black Hamburg; Mr. Tickle, gardener to Mrs. Stodhert, being a close second; and Miss Marriott third.

Melons, though fairly numerous, were not of great merit. The principal prizewinners with these were Messrs. R. Hull, Chippenham; H.

Chislett, gardener to E. T. D. Foxcroft, Esq.; J. Gibson, W. Coombes, gardener to W. Langdon, Esq.; J. Mabbett; W. Allen, gardener to T. G. P. Hallett, Esq.; and C. Adlam. Peaches were extensively shown and in some instances were very good. Mr. T. Wilkins had a first prize for a grand dish of Sea Eagle, and Mr. W. Iggulden a first for Barrington in good condition, other prizewinners being Messrs. T. Jones, Cray, and Pymm; the last named had a first prize in the class for Nectarines for very fine Pine Apple, Mr. T. Wilkins being second with good Albert Victor. In another class Mr. Marchant was first and Mr. C. Trimby, gardener to J. W. Dunn, Esq., second. Mr. D. Deverill, Farleigh Castle, was first for Figs, staging good Brunswick, Mr. W. Iggulden being second with Brown Turkey. Plums in three classes were far more plentiful than anticipated. In the class for any dessert variety Mr. W. Iggulden was first for a pretty dish of Early Transparent Gage, Mr. R. Denton being second with good Jefferson. Mr. W. Smith was first with Green Gages and second with culinary Plums, Mr. G. H. Osborn taking first for the latter with a fine dish of Diamond. Mr. Buckley was first for Cherries, Mr. W. Evry for Filberts, and Mr. C. Rickets for Nuts, the competition being good in each instance. A fine dish of Clapp's Favourite won Mr. G. Horsell a first prize for dessert Pears, Mr. Jones being second, and there were other classes for Pears and also dessert and culinary Apples, but the prize cards were put on too late for the names to be taken.

Vegetables were very fine, everything in season being provided for and well represented. The best twelve varieties were shown by Mr. T. Wilkins, who had five dishes of Cauliflowers, Autumn Giant; Parsnip, The Student; Celery, Veitch's Giant White; Beet, Pragnell's Exhibition; Tomato, Perfection; Runner Beans, Veitch's Mammoth; Potato, Satisfaction; Carrot, Veitch's Intermediate; Leek, Lyon; Pea, Prodigy; and Cucumber, Allan's Favourite. Mr. G. H. Copp was second, and Mr. G. Garraway, third. There was a grand display of Tomatoes, but Mr. Holbrook, gardener to Mrs. Beddo, was well first with Clibran's Perfection, extra good; Mr. T. Wilkins was second, and Mr. J. Deacon third. The best basket of salad came from Mr. T. J. Tate. Special prizes were provided for collections of vegetables by Messrs. Sutton and Sons, Reading, and Messrs. Webb & Sons, Stourbridge, and collections of Potatoes by Messrs. Cooling & Sons, Bath; the competition for all of which was close and good. The principal prizewinners were Messrs. Wilkins, Copp, Garraway, J. Deacon, W. Evry, and J. Hall. Cottagers also made a good display of vegetables.

Among the most noteworthy of the non-competitive exhibits were displays of cut Begonias in fine variety by Mr. B. R. Davis, Yeovil, and the Rev. E. Lascelles, near Bath, the last named also having several plants in pots of superior varieties. Messrs. Cooling & Son filled a large table with Apple trees in pots, beautifully fruited, and a great variety of Apples in dishes. Some of the best represented varieties were Emperor Alexander, Lord Grosvenor, Lord Suffield, Stirling Castle, Domino, Beauty of Bath, Prince Albert, Worcester Pearmain, Duchess of Oldenburg, Potts' Seedling, Golden Spire, The Queen, Cox's Pomona, Bismarck, and Belle de Poulise. Messrs. Jarman & Co., Chard, also staged a capital lot of Apples and other fruit, including fine bunches of Hamburgh Grapes, with vegetables in good variety, Dahlias, Roses, and herbaceous flowers.

BRIGHTON.—AUGUST 27TH AND 28TH.

A NEW era has opened in connection with horticulture at Brighton, and one in which there is great hope for the future. It is not necessary to particularise the causes which led up to the formation of a new Society there a few months ago, for the unsatisfactory state of things that they resulted in has been fully remedied; but it is only just to indicate how completely the action of those who set to work to substitute a fresh society for the old one has been vindicated. They encountered great obstacles, and no doubt their action was misunderstood by many of those who were not sufficiently behind the scenes to appreciate the necessity for vigorous measures, but they pursued their course with energy, foresight, and discrimination, the result being an accession of influential supporters that speedily placed the success of the movement beyond doubt. When last week the summer Show afforded an opportunity of testing the metal of the young Society its strength was triumphantly asserted. The Exhibition was far the best of its kind ever held in Brighton. The prize list was arranged with a judgment and liberality that commanded large entries and the co-operation of some of the best-known exhibitors in the South of England. In every department the quality was of a high order, and it only remains to express a hope that the Society will go on as it has begun, then it may confidently be expected to become one of the most powerful local organisations in the country.

In our last issue we indicated the success of Mr. Peel, gardener to Miss Todd, Southampton, in the leading class for groups. The space to be covered was 100 square feet, and the first prize consisted of a shilling for each square foot, or £5. Mr. Peel had a very attractive arrangement—bright, but not heavy; and well merited the premier award. The plants were not striking individually, but were clean, healthy, and well balanced. Mr. Turner, gardener to Sir G. Smyth, Wick Hall, was second; and Mr. G. Miles, nurseryman, Brighton, third. A second group was asked for to cover a space not exceeding 60 square feet, a first prize of £3 being offered; this fell to Mr. Meachin, gardener to Mrs. Armstrong, Woodlee; Mr. Fry, gardener to C. Catt, Esq., following. These exhibitors had both done their work with taste. A third group was to be composed of Ferns, and to cover a space not exceeding 80 square feet. Mr. G. Miles won here with an arrangement

that had evidently been well thought out, departing in several respects from the conventional lines. Mr. W. Miles was second; and Mr. Jupp, gardener to G. Boulton, Esq., third. The latter was placed first for an effectively arranged table of plants; and Mr. Murrell, gardener to Mrs. Macdonald, for a table of Begonias. In both cases well-grown material was used with judgment.

Reference was made last week to the magnificent specimens staged by Mr. Offer, gardener to J. Warren, Esq., Handcross Park, Crawley, and with which he easily secured the first prize of £10 in the class for twelve stove and greenhouse plants. His Crotons were wonderful examples of size combined with fine colour and perfect cleanliness. C. Prince of Wales was splendid, as were the Lapagerias, Ericas, Allamanda Hendersoni, and Dipladenia amabilis. Mr. Portnall, gardener to Sir A. Lamb, Bart., was second, and Mr. Meachen third, both showing healthy material. Mr. Jupp, wisely reserving his best plants for the smaller class, was placed first for six, and did himself full justice. Mr. Offer easily secured the premier award for six Crotons, his plants of undulatus, Sunset, and Williamsi being particularly fine, and he won again with six Dracenas, the minor prizes going to Messrs. E. D. Shuttleworth & Co. and Mr. Turner. The best specimen ornamental foliage plant and the best specimen flowering stove and greenhouse plant both came from Mr. Warren, the former being the grand Croton Weismanni which has been admired by many visitors to metropolitan exhibitions. Mr. Duncan won with four Orchids, and other prizes in the plant classes went to Messrs. W. Miles, A. Fry, Jupp, and Stovel.

Dahlias being the principal flowers in season were strongly represented in the cut flower classes. Mr. Humphries, Kington Langley, who has exhibited remarkably well this year, was first with forty-eight blooms, staging smooth, fresh, but not large flowers. Mr. M. V. Seale, Sevenoaks, was a very good second, and Mr. Such, Maidenhead, third. In the class for twenty-four blooms, Messrs. Cheal & Sons, Lowfield Nurseries, Crawley, were first for excellent examples; Mr. Mitchell, gardener to Sir J. Colquhoun, Bart., second, and Mr. Dawson, St. Leonards, third. The Crawley growers were to the fore again with twelve blooms, and also, as might be expected, with Cactus and single varieties. The two last were extremely beautiful, the flowers being notable for good type, clear colours and perfect freshness rather than large size. Mr. Seale was second for Cactus varieties, but first for Pompons, which he showed remarkably well. Messrs. Cheal & Son were placed first for Gladioli. There were three classes for Roses. In the first, that for twenty-four varieties, Mr. Woollard, Cooksbridge, was first, and in the others, Mr. H. Harris, gardener to Mrs. Eversfield, Horsham, was the most successful. Mr. Archer, gardener to Miss Gibson, Saffron Walden, won with twenty-four varieties of stove and greenhouse flowers, and Mr. Duncan with twelve varieties, the minor awards falling to Messrs. Gore, Blake, and Offer. The other cut flower classes were too numerous to be particularised, but it may be noted that Messrs. Pritchard, Manton, Such, Sage, Sutton, Peel, Seale, Chard, Potter, and Chadwick showed prominently in them.

Fruit was an excellent display. The principal class was that for eight dishes, prizes of £5 £3, and £2 being offered. The first was secured by Mr. Reynolds, gardener to Messrs. de Rothschild, Gunnersbury Park, Acton, who had excellent bunches of Gros Maroc and Muscat of Alexandria Grapes, a good Pine and Melon, Clapp's Favourite Pears, large Brown Turkey Figs, Sea Eagle Peaches, and La Grosse Sucrée Strawberries. Mr. Sage, gardener to Earl Dysart, Ham House, Richmond, Surrey, was second; and Mr. Potter third. Mr. Reynolds also showed splendidly in the Grape classes, being represented by the same varieties as he had in his first prize collection in each of the classes for three bunches. Mr. Webster, gardener to Dr. Kirby, was first with one bunch of a black variety, showing Madresfield Court; other prizes in the Grape classes going to Messrs. Spottiswood and Coleman. Apples, Peaches, Plums, and Cherries were all good. Mr. Reynolds won with culinary Apples, and Mr. Miller with dessert varieties, both having splendid dishes. The smaller awards went to Messrs. Sage, Stringer, Blake, and Sands. Mr. Potter was the most successful with Peaches, Mr. Duncan with Cherries, and Messrs. Harris & Didman with Plums.

MOSELEY BOTANICAL GARDENS AND COLLEGE GROUNDS, BIRMINGHAM.—AUGUST 30TH AND 31ST.

WE gave a report of the Rose Show here in July, when a terrible hurricane blew down one tent, and we have to record another unfortunate experience with the Dahlia Exhibition on August 30th and 31st. It rained incessantly and blew a great gale, but the tent men stuck to their work night and day, and no damage was done to any exhibits.

Substantial prizes were offered for collections of Dahlias, all kinds admissible, to occupy a space of not less than 12 feet by 3 feet wide, and seven collections were staged, each from 15 to 20 feet long. They formed a grand bank of flowers, and Dahlias are most effective when displayed in this way. The first prize was well won by Messrs. Perkins and Sons, Coventry, with an artistically set up group, show flowers on the usual boards being arranged in front with pretty bunches of Pompons and other decorative varieties, the Pompons predominating in formal bunches, and attractive baskets and bouquets of Dahlias were added, the back rising to about 2½ feet high. Messrs. Jones & Sons, Shrewsbury, had a very fine display, which took the second prize, and Messrs. Kimberley & Son, Stoke, Coventry, were third, their flowers being neatly staged, but a little heavy in arrangement. The classes for thirty-six and twenty-four Dahlias were well filled, Messrs. Heath and

Son, Cheltenham, keeping to the front; other leading growers also exhibiting.

A very fine bank of hardy border flowers was staged for the prizes offered for them, and in the class for twenty-four distinct kinds, Mr. W. B. Child, Acocks Green, was first, and Messrs. Harkness & Sons second, showing in their usual style.

Fruit also was made a leading feature, and prizes of £5, £4, and £3 were offered for a collection of eight varieties, and five exhibits were staged. First, Mr. James Dawes, gardener to H. M. Biddulph, Esq., M.P., Ledbury Park, with two grand bunches of Gros Maroc Grapes, two of Muscat of Alexandria, an excellent La Favorite Melon, very fine Barrington Peaches, and Humboldt Nectarines, Roman Apricots, and Figs. Second, Mr. T. Roberts, gardener to H. W. Foley, Esq., Prestwood, Stourbridge, with excellent Alicantes, Muscats, splendid Brunswick Figs, fine Grosse Mignonne Peaches, Hemskerk Apricots, Pitmaston Orange Nectarines, and other fruits. Third, Mr. Gilman, Ingestrie, who had in his collection Hero of Loeking Melon, Hamburgh and Muscat Grapes, Lord Napier Nectarines, Apricots, and Figs, all good. Fourth, Mr. Bannerman, Blithfield. For three bunches of Black Hamburgh Grapes Mr. Bannerman was first with some fine examples; second, Mr. A. J. Pass, Birmingham; third, A. Bird, Esq., Birmingham. For three bunches of Muscat of Alexandria, first, Mr. Bannerman; second, Mr. Wm. Shaw, Kidderminster. For three bunches of any other black: first, Mr. Bannerman, with fine Alicantes; second, Mr. W. Shaw, with Gros Maroc; third, Mr. Gilman, with small bunches, but beautifully coloured, of Gros Maroc. Extra, Mr. Lister Lea. Mr. T. Pritchard, Umberslade Hall Gardens, staged eight fine Queen Pines, a fruit of Enville Queen being especially good, and a first-class certificate was awarded to it.

The local gardeners also had fruit classes which were well filled. Mr. Stainton, Stoneleigh, near Kenilworth, near to the celebrated Stoneleigh Abbey, Lord Leigh's residence, sent two dozen very large fruits of Williams' Bon Chrétien Pears from a wall, very fine examples such as one rarely sees; and Messrs. Bunyard & Sons, Maidstone, contributed fifty-six dishes of Apples and Pears and eight baskets of Apples. It was a very fine display, and was greatly admired by those who braved the weather. The Apples had been selected more to show their character than extreme size, and were all round a fine lot, colour predominating. Of the dessert Apples, Okera, a Russian variety, is a coloured fruit of good flavour and a good keeper. Beauty of Bath is a handsome flattish fruit, very early and excellent. Cardinal (or Peter the Great) a handsome fruit, rich in colour, a wonderful cropper of fine quality. Duchess of Gloucester becomes a bright scarlet, a medium-sized Apple, keeping to Christmas. Amongst the kitchen varieties Washington, large and handsome and nicely coloured, and Seaton House, with many old varieties, were all very fine. Bismarek, an Australian variety and an immense cropper, is a large heavy solid fruit, a late keeper, and becomes rich in colour. Gold Medal is of the Ecklinville type, it becomes quite yellow, keeps longer, and is even a better cropper.

Messrs. Sutton & Sons, Reading, sent a grand lot of their choice Gloxinias, including Her Majesty, Cyclops, Admiration, and Duke of York, to all of which first-class certificates were awarded. A display of improved Phlox Drummondii and other annuals was also made. Mr. Hy. Eckford, Wem, sent a collection of his lovely Sweet Peas, and first-class certificates were awarded to Venus, Lord Beaconsfield, Ovid, H. M. Stanley, Lady Penzance, and Royal Robe, all yet to be sent out, and beautiful acquisitions. A first-class certificate was awarded to Messrs. Perkins & Sons, Coventry, for a new Cactus Dahlia named Matchless, a rich deep crimson maroon, almost black, and of very fine quality; and first-class certificates were awarded to Mr. Charles Turner, Slough, for four very fine seedling Cactus Dahlias—viz., H. E. Milner, a lovely buff tinted pink; Sir Hugo, a grand scarlet; Blushing Bride, white; and Joseph Chamberlain, orange tinted buff; also to Pompon Little Lady, cream tinted with bright rosy carmine. Mr. Harry Whateley, Spring Gardens, Kenilworth, sent two dozen grand fruits of the American Tomato Ignatum, very fine indeed. Messrs. Pope and Sons contributed a wreath and a very lovely shower bouquet. Messrs. Hewitt & Co. had a bank of bloom 40 feet long, and nearly 4 feet wide. Messrs. Thomson & Co. also set up a fine display of herbaceous blooms, Violas in pots, a fine lot of Carnation and Picotee blooms, including some of Benary's new ones, and three of their seedling fine rose flakes. Messrs. Harkness & Sons had an attractive exhibit. Messrs. Shaw, and Jones & Sons, had collections of Gladioli; Mr. Robert Sydenham a display of prize vegetables from his seed.

A very fine lot of specimen Begonias were staged by F. Jenkins, Esq., Birmingham. A stage 30 feet long, by 7 feet wide, and 1 foot in height, covered with green baize, was erected especially for them, and thirty grand specimens in full bloom were somewhat crowded in the space; a special first-class certificate for culture and excellence was awarded to them.

READING.—AUGUST 31st.

WHILST last year this excellent provincial Society had to suffer on the day preceeding the Show from a terrific wind storm, which tore its fine tent into pieces; this year there was a visitation of rain during the afternoon, which materially affected the attendance, as well as comfort, and drove visitors to the shelter of the small tents that had been erected, far too much for anyone's enjoyment. Later the attendance, happily, was very large, when rain ceased. The site of the Show was the beautiful Forbury Gardens. There is in the gardens no ample grass area, hence the Show, as far as could be, was distributed in several small tents, much to its demerit; and all the vegetables had to

be staged outdoors, much to their deterioration. It need hardly be said that if the Reading Horticultural Society is to occupy a position worthy of the prosperous and distinguished town which gives it a name a very big effort must be made another year to find, not only a fitting place for the Show, affording ample tent room, but also that much must be done to make the autumn Show what it ought to be—the finest, most attractive, and most popular of all home counties exhibitions.

If, for once departing from ordinary formula, we give the vegetables the pride of place in this report it is because these formed so striking a feature of the Show; indeed, a better display of these useful products can hardly be seen anywhere. With such high-class and formidable competitors as Messrs. Lye of Sydmonton Court, Pope of Highclere Castle, Bowerman of Hackwood Park, Waite of Esher, Kneller of Malshanger, and Best of The Vine, and such donors of liberal prizes as Messrs. Jas. Carter & Co., High Holborn, Webb of Wordsley, Fidler of Reading, and last though very far from least, the famous firm of Messrs. Sutton and Sons, Reading, no wonder the exhibits were of the very best quality, and the competitions stoutly contested.

First in the schedule came the prizes of Messrs. Carter & Co. for an unlimited class. There were three competitors, and a total of sixty-four dishes. Mr. Pope, gardener to the Earl of Carnarvon, Highclere Castle, was first, having very good Autumn Giant Cauliflowers, Giant White and Sulham Prize Celeries, Adirondack and The Canon Potatoes, Perfection Tomatoes, Canadian Wonder Dwarf and Jubilee Runner Bean, Rousham Park Hero Onions, &c. Mr. M. Lye, gardener to W. G. Kingsmill, Esq., Sydmonton Court, was second, having very handsome samples of Holborn Onions, Model Leeks, Perfection Beet, Giant Cauliflowers, Telephone Peas, Jubilee Runner Beans, Solid Ivory White and Standard Bearer Celeries, Scarlet Intermediate Carrots, Model Cucumbers, &c. Third Mr. Waite, gardener to the Hon. Colonel Falbot, Glenhurst, Esher, whose collection of twenty-four dishes lacked the best average quality, but included most of the above varieties.

Nine lots of six varieties competed for Messrs. Webb & Sons' prizes. Here Mr. Kneller, gardener to W. Portal, Esq., Malshanger, who was not very strong at Basingstoke, surprised his friends with the high excellence of his exhibits, and was placed first. He had gigantic Rousham Park Hero Onions, good Perfection Tomatoes, fine Satisfaction Potatoes, handsome Ne Plus Ultra Runner Beans, excellent Autumn Giant Cauliflowers, and fine New Intermediate Carrots. Mr. Bowerman, gardener to C. Hoare, Esq., Hackwood Park, who also had superb exhibits, was second with good Cauliflowers, though perhaps his weakest dish; very fine Ailsa Craig Onions, handsome Defiance Carrots, good Duke of Albany Peas, Sensation Tomato, and Satisfaction Potato. Mr. Waite came third, having rather too large Satisfaction Potato, similar Carrots, Peas, and Cauliflowers to the preceding; Onions and Tomatoes. Mr. W. Pope was fourth. Six collections competed for the prizes offered by Mr. C. Fidler of Reading, the first of which was a much coveted gold medal and two guineas. Here Mr. Lye used all his strength, his six kinds being practically unbeatable anywhere. He had Autumn Giant Cauliflowers, Giant Zittau Onions, Perfection Tomatoes, Ne Plus Ultra Runner Beans, a perfect sample; Wright's Grove White Celery, beautifully blanched; and very handsome Satisfaction Potatoes. Mr. Kneller was second with immense Anglo-Spanish Onions, Perfection Tomatoes, good Cauliflowers, too large, but very handsome; Intermediate Carrots, Satisfaction Potatoes, and Clayworth Prize Celery. Mr. Best, gardener to Mrs. Chute, The Vine, was third; and Mr. Bowerman, generally having the same varieties, was fourth.

Messrs. Sutton & Sons of Reading did not offer prizes for collections, but gave thirty-six prizes for twelve kinds of vegetables in separate classes—a liberal total, including a class for Melons, of £11 14s. In most of these single dish classes there was good competition and high quality. It is worthy of mention that varieties were left absolutely open. Beet came first with sixteen lots, Mr. Bowerman being first with rather too large and a little coarse samples of Sutton's Blood Red. Mr. Waite was second with smaller but very handsome samples of the same varieties. Mr. Best was third. With Carrots, of which twelve lots were staged, Mr. Bowerman was again first with very fine and even shaped, but hardly sufficiently smooth sorts of New Intermediate; Mr. Kneller coming second with rather smaller, but singularly handsome examples; Mr. Lye was third, both having the Intermediate. Of Celery only six lots were staged, Mr. Waite coming first with Sutton's Solid White, very good; Mr. Pope being second with Sutton's Al Pink variety, and Mr. Best third with Sulham Prize. Cauliflowers were few also, five lots of three heads being staged. Mr. Best was first; Mr. Frost, gardener to W. A. Palmer, Esq., Reading, second; and Mr. Pope third, all with Autumn Mammoth. Leeks were very good, and here, oddly enough, the Judges, who in another single dish class had placed the Long Prizetaker Leeks before the dwarf thick Onion-rooted Lyon, reversed their decision, placing the thick Lyon shown by Mr. Pope, about 5 inches of the stems blanched, before the beautiful Long Prizetaker from Mr. Lye, which had 9 inches of blanched stems. Mr. Kneller was third. There were twelve bunches of six Turnips, Mr. Lye coming first with handsome Snowball; Mr. Bowerman was second, and Mr. Booker, gardener to W. B. Mouch, Esq., third with the same variety. There were twelve lots of six Onions in competition, the prize lots standing out a long way before the others. Mr. Kneller was first with very fine but rather spotted samples of Sutton's Exhibition, Mr. Lye being second with the same variety but brighter, Mr. Pope coming third with a capital sample of Improved Reading. Mr. Turton, gardener to J. Hargreaves, Esq., Maiden Erlegh, had of ten lots the finest Cos Lettuces in Sutton's Mammoth White, Mr.

Waite coming second with the same very fine variety, and Mr. Kneller was third. With Cabbage Lettuces Mr. W. Palmer of Andover, Mr. Turton, and Mr. Lye took the prizes, all having that very fine variety Sutton's Favourite, which has slightly curled leafage. In the class for six Parsnips, of which kind fourteen lots were staged, Mr. Maxim, gardener to the Hon. Miss Lefevre, Heckfield Place, was first with very fine but rather rough skinned Student, Mr. Pope coming second with very handsome samples, and Mr. Booker was third. Tomatoes brought more moderate competition. The awards were surprising, as the first and second prize fruits were big and had large brown centres, both serious defects. Mr. Callender, Henley, was first; and Mr. Mackay, Penn, was second; Mr. Waite, who had a beautiful dish of Perfection, coming third. There were fourteen dishes of Peas. Mr. Goodman, gardener to Miss Hammersley, Marlow, had Duke of Albany for first; Mr. Bowerman was second with Main Crop Marrow; Mr. Pope was third. The latter was, however, first in the Runner Bean class with somewhat large Al, Mr. Bowerman coming second, and Mr. Lye third with the same variety, but all a trifle too old. A truly beautiful dish from Mr. Kneller, younger and more perfect, was oddly overlooked. For prizes offered by Messrs. John Sharpe & Sons the competition was poor. Mr. Waite had the best Tomatoes and Mr. Kneller the best Carrots.

Such a remarkably fine lot of vegetables as was here staged deserved better treatment than exposure to wind and rain, and would have made a splendid show if properly arranged in a large tent. Of Tomatoes shown, not for competition, there were fine lots from Mr. Churchman, Nottingham; Mr. F. Lees, Reading; and Mr. Bradley, Tilehurst. Cucumbers, in the Society's classes, produced a truly beautiful brace of Sutton's Matchless from Mr. Mortimer, Farnham, who was first, Mr. Smeller being second with Telegraph.

Fruit was remarkably good, as it always is at Reading. Mr. Maxim had the best collection of eight dishes, having good Mrs. Pince and Golden Queen Grapes, Sea Eagle Peaches, Lord Napier Nectarines, &c. Mr. Goodman, who was second, was weak in Grapes, but had capital other fruits. Mr. Smith, gardener to M. Overy, Esq., Badgemore, was first with six dishes, having heavy Alicante and Muscat Grapes, Barrington Peaches, Elruge Nectarines, &c. Mr. Johnson, gardener to A. Gilliat, Esq., Slough, was second. Crawford's Early Peach was with him wonderfully coloured. Mr. Waite was third. Mr. Osman, Otter-shaw Park, had the best three bunches of Black Hamburgh Grapes, Mr. Turton coming second. Mr. Maxim was first with good clean Alicante in the class for any other black, Mr. J. Pound, gardener to Alfred Sutton, Esq., coming second with the same variety, very fine clusters. Mr. Smith had the best white Grapes in well coloured Muscat of Alexandria, Mr. Pound again being second with fine bunches, hardly ripe. These same exhibitors came first and second in the class for any other white, having good Golden Queen and Buckland Sweetwater respectively. With six dishes of dessert Apples Mr. Turton was first, having handsome rich-coloured Strawberry, Worcester Pearmain, Duchess's Favourite, Irish Peach, Astrachan, and Kerry Pippin. Mr. Paxton, gardener to Hon. C. P. Irby, Taplow, was second. With six dishes of kitchen Apples Mr. Turton and Mr. Dockerill, gardener to G. W. Palmer, Esq., M.P., Reading, were placed equal first, so very fine and even were their samples. The former had Lord Suffield, Warner's King, Saltmarsh's Queen, Peasgood's Nonesuch, Waltham Abbey Seedling, and Ecklinville; the latter had Peasgood's, Bramley's Seedling (very fine), Emperor Alexander, Stirling Castle, Ecklinville, and Lord Suffield. Mr. Goodman was placed second. Pears were of moderate quality. Mr. Paxton had the best dish of Figs, and Mr. Bowerman with Barrington, a superb dish of Peaches. Mr. Bowerman was also first with very fine Humboldt Nectarines, Mr. Pound coming second with Pineapple. Mr. Waite had the best three dishes of Plums, and Mr. Dockerill had the best brace of Melons and the best single Melon with Hero of Lockinge, though much over-ripe, the flesh being soft and pulpy.

Cut flowers were very fair. Mr. Mortimer and Messrs. Cheal & Sons had the best double Dahlias, and the latter the best bunches of single Dahlias. Messrs. Perkins & Sons of Coventry had beautiful Roses, Mr. Turton the best Zinnias, Mr. Such, Maidenhead, beautiful Phloxes, Mr. Phippen very fine wreaths and crosses. Mr. Finch had a grand lot of bunches of cut flowers, Mr. Best good Asters. The length of the report necessitates leaving plants unnoticed beyond saying that, whilst some were good, groups were poor.

WIRRAL.—AUGUST 31ST AND SEPTEMBER 1ST.

THE fiftieth annual Exhibition of the above Society was held in connection with the Birkenhead and Wirral Agricultural Show in the Bidston Show Ground. Unfortunately for the Society the weather on the first day was very wet, and a great decrease in gate money was the result; but on the second day the weather was decidedly better, and the attendance excellent. As regards entries, which numbered 850, they were far in advance of former years, and an excellent show in every department was the result. Groups and cut flowers were abundant, and of the finest description. Fruit was very fine, and vegetables superb.

For five foliage and the same number of flowering plants Mr. A. Brown, gardener to Geo. Webster, Esq., Claughton, was first with excellent examples, and throughout the whole of the classes the same exhibitor held his ground, gaining first prizes for three stove and greenhouse plants, three foliage plants, three Ferns, three Lycopods, one greenhouse and one stove plant in bloom, one foliage plant, one Fern, one Fuchsia, twelve Asters, six Asters, twelve varieties of cut flowers,

six dessert Apples, and six Plums, the more credit being due to him owing to strong competition in some of the classes.

In the group arranged for effect Mr. S. Haines, gardener to Macgregor Laird, Esq., was deservedly first. The prizes for one Palm, table plants, Gladioli, and six varieties of cut flowers (indoor), and the same number of outdoor were awarded to Mr. J. Bounds, gardener to A. L. Jones, Esq., Oaklands, Aigburth. The prizes for twelve and six Dahlias went to Mr. J. Lee, whilst that for twelve Cacti was awarded to Mr. T. Woolrich, and for six to Mr. J. H. Howell. The classes for twelve and three varieties of outdoor cut flowers, everlasting flowers, and hand bouquets were taken by Messrs. W. B. Burnham, John Wynne, C. J. Proctor, and Wm. Henderson.

In the class for six dishes of fruit Mr. W. Oldham, gardener to J. Beecham, Esq., Ewanville, Huxton, just succeeded in beating Mr. T. Ferguson, gardener to Mrs. Paterson, Rock Ferry, both having splendid dishes; the third place being occupied by Mr. Hannagan, gardener to R. C. Naylor, Esq., Hooton Hall. The best collection of hardy fruits was shown by Mr. C. Worker, gardener to Mrs. Blomfield. The Grape classes were strongly contested, the prizes for Hamburgs and any other black going to Mr. Bramball, gardener to G. C. Sinclair, Esq., with superb bunches. The prizes for Muscat of Alexandria and any other white were taken by Messrs. J. Heap and J. Downham, gardener to E. H. Harrison, Esq., Eastham. For six Peaches Mr. Ferguson was first with a magnificent dish of Sea Eagle; and six Nectarines, very fine fruits of Pineapple, secured Mr. Oldham the first position. The prizes for scarlet and green-flesh Melons went to Messrs. Heap and Ferguson, the latter winning in the class for six Jargonelle Pears, and Mr. T. Watkinson in that for any other variety. Mr. C. Worker won with Green Gage Plums.

Vegetables in the local class, eight varieties, were best shown by C. J. Proctor, Esq.; and for the same number, open, by Mr. T. Smetham, Leaton Knolls, Shrewsbury, with splendid exhibits; the latter also winning first places with two Cauliflowers, two roots of Parsley, six Parsnips, and six Carrots. Mr. T. Woolrich won with twelve coloured Potatoes (round), green and red Cabbages. Mr. W. Lancellotte was first with twelve white (round) and twelve kidney (coloured) Potatoes, twelve Shallots, and six Beetroots. The prizes for twelve white kidney Potatoes, twelve Leeks, twelve spring Onions, French Beans, Scarlet Runners, Peas, Cucumbers, Celery, and Vegetable Marrows were awarded to Messrs. Pigott, Dickson, Worker, Bennett, Burnham, Clarke, Condon, Leach, and Lawton. Mr. J. Lee secured that for twelve Tomatoes.

Mr. Henry Middlehurst, Manchester Street, Liverpool, was awarded the gold medal of the Society for the best collection of garden and farm seeds and produce; Dicksons (Ld.), Chester, receiving the silver medal. In the classes for bees Mr. P. Harbordt, Covent Garden Seed Stores, Liverpool, was most successful.

NATIONAL DAHLIA SOCIETY AT THE CRYSTAL PALACE, SEPTEMBER 2ND AND 3RD.

Is the Dahlia losing its popularity? One might be tempted to think so from the little interest that appeared to be taken in the opening of the National Show on Friday last. There were very few people present, and no signs of the lively interest that used to be manifested in the flowers. Or is it that the Show suffered from the absence of the measures usually taken to make the Sydenham gatherings known to the gardening fraternity? There may be something in this. The average visitor is apt to let a fixture slip by unless he has a special reminder of its coming. If he is accustomed to have his memory freshened by advertisements it is not unnatural for him to think that in their absence there is nothing to advertise, and so the shows suffer. Whatever may be the cause, exhibitors, judges, and reporters had matters pretty much to themselves on the first day of the Show.

The flowers were not quite up to the usual standard so far as size is concerned, the Show and Fancy blooms ruling somewhat small throughout, but in other respects there was nothing to find fault with. Messrs. Keynes, Williams & Co. were prominent in the trade classes, while in the amateurs' section that well-known exhibitor, Mr. J. T. West, and Mr. Sidney Cooper had very fine blooms. Cactus and Decorative varieties were very finely shown, and Pompons were good. Singles were somewhat scarce, but the quality was excellent. We have seen them larger, but that is no advantage.

SHOW AND FANCY.—There were four stands of sixty blooms, Show and Fancy intermixed, in the leading trade class, the best being that of Messrs. Keynes, Williams & Co., Salisbury, whose flowers were very bright and even, although hardly so heavy as some previous winning stands in this class have been. The varieties were as follows:—Back row: Harrison Weir, Rebecca (self), Mrs. Kendal (a splendid bloom), James O'Brien (also a fine example), Shirley Hibberd, Mr. Glascock (a large and heavy flower), Duchess of Albany, Colonel, Royal Queen, J. N. Keynes, R. Dean, Rebecca, Rev. J. B. M. Camm, Seedling, John Hickling, Buffalo Bill, Gloire de Lyon (very fine), Geo. Hurst, Arthur Ocock and William Rawlings. Middle row: Thos. Hobbs, J. T. Saltmarsh, J. T. West, Imperial, Matthew Campbell, J. C. Vaughan, Robina, James Cocker, Dandy, James Huntley, a sport, Alice Emily, T. S. Ware, Maud Fellowes, Willie Garratt, a seedling, Duke of Fife, William Powell, Mrs. J. Downie, and Harry Keith. The first eight were somewhat undersized but otherwise good in every way. Front row: Mrs. Langtry, Mrs. Stancomb, Rosetta, Comte de la Saux, Crimson Globe, Comedian, Eclipse, Chorister, Arthur Rawlings, Miss Fox, John Walker, Henry Bond, Miss Cannell, a sport, Mrs. Gladstone, Sunset, Hon. Mrs. Wyndham,

Nellie Cramond, Frank Pearce, and a seedling. Mr. Charles Turner, Royal Nurseries, Slough, had an extremely beautiful collection, the flowers being in perfect condition. They lost points in the matter of size however. Amongst the best were Maud Fellowes, a seedling of very much the same character, but a shade deeper in colour, Agnes, Grand Sultan, Mrs. Slack, and Duchess of Albany. Mr. Arthur Rawlings, Romford, was third with fresh but somewhat uneven flowers, many being very small, and Mr. M. V. Seale, Sevenoaks, fourth.

There were four stands of forty-eight blooms, and Messrs. Keynes, Williams & Co. were again first. Lack of size was very noticeable in this stand, but in other respects there was nothing to cavil at, for the blooms were smooth, even, and remarkably clean. The following were the varieties represented:—Back row: Jas. O'Brien, Pelican, Mr. Glasscock, Harrison Weir, Gloire de Lyon, Colonist, R. Dean, Duchess of Albany, Mrs. Foreman, John Hickling, Mrs. Langtry, Jas. Cocker, Rev. J. B. M. Camm, Royal Queen, William Powell, and William Rawlings. Middle row: Hon. Mrs. Wyndham, Matthew Campbell, a sport, Thos. Hobbs, Buffalo Bill (very good), Mr. Spofforth, Maud Fellowes, Rosetta, Mrs. J. Downie, Miss Barber, J. N. Keynes, Mrs. Langtry, Shirley Hibberd, J. T. West, and two seedlings. Front row: Jas. Huntley, J. B. Service, Diadem, John Walker, Miss Cannell, J. C. Vaughan, Frank Pearce, Nellie Cramond, Comedian, Victor, Crimson Globe, Thos. Goodwin, Willie Garratt, Imperial, Miss Fox, and Mrs. Gladstone. Mr. Turner followed with neat, well-coloured blooms; Mr. Rawlings was third, and Mr. Seale fourth, so that this class was an exact repetition of the other.

Four competed again in the class for thirty-six blooms, and this brought out one of the best stands in the Show, that of Messrs. Saltmarsh & Son, Chelmsford. The flowers were not of the largest size, but they were far from being small, while they were excellent alike in freshness and finish. The varieties were as follows:—Back row: Perfection, W. Rawlings, Harrison Weir, James Cocker, Henrietta, Rev. J. Goodday, Maud Fellowes, Harry Veitch, Rev. J. B. M. Camm, Hugh Austin (self), Mrs. Saunders, and Mr. Glasscock. Middle row: Shirley Hibberd, T. J. Saltmarsh, H. Walton, J. Walker, W. Keith, Frank Pearce, A. Ocock, R. T. Rawlings, Mrs. J. Downie (self), Mrs. Saunders, W. Garratt, and J. T. West. Front row: Mrs. Langtry, Crimson Globe, Miss Barber, T. S. Ware, Constancy, Lustrous, Lady Herbert, Mr. Harris, M. Campbell, Lady Chelmsford, Mrs. Gladstone, and T. W. Girdlestone. Mr. G. Humphries, Kingston Langley, Chippenham, was a very close second indeed. There could not have been more than a point or two between the two stands. His flowers were of medium size, even, and very fresh. Mr. S. Mortimer, Rowledge, Farnham, was third; and Mr. John Walker, Thame, fourth. Five competed with twenty-four blooms, and the stands comprised a considerable number of fine flowers. Mr. Humphries was first with an admirable stand, staging Harry Keith, J. Walker, Buffalo Bill, W. Powell, W. Rawlings, Mrs. Gladstone, Purple Prince, H. Walton, R. T. Rawlings, J. Cocker, Colonist, F. Pearce, Duchess of Albany, George Barnes (self), Salamander, Arthur Rawlings, Miss Cannell, Volunteer, Mrs. Kendal, Victor, H. Bond, Mrs. Langtry, Mrs. Saunders, and Mrs. Downie. A very good stand from Messrs. Saltmarsh & Son, comprising neat, fresh blooms, secured the second prize; the third went to Mr. Mortimer; and the fourth to Mr. J. Walker. Messrs. Cheal & Sons, Lowfield Nurseries, Crawley, had the best out of the four stands of twelve, good sized, clean, and brightly coloured examples of Colonist, Crimson King, J. T. West, Lord Chelmsford, Matthew Campbell, Mrs. Foreman, John Walker, Mrs. P. Mackenzie, Mrs. Gladstone, Mrs. Langtry, Nellie Cramond, and Mrs. Jefford securing them the award. Mr. J. R. Tranter, Henley-on-Thames, was second with good flowers; Mr. H. Harris, Chelmsford, third; and Mr. J. Wood, Burton-on-Trent, fourth.

The amateurs mustered strongly in the principal class reserved for them, that for twenty-four blooms, eight competing. The successful exhibitor was Mr. J. T. West, gardener to W. Keith, Esq., Cornwalls, Brentford, and his flowers, though noticeably under the average in point of weight, were smooth, even, fresh, and well coloured. His varieties were as follows:—Back row: R. T. Rawlings, Harry Keith (very fine), Queen of the Belgians, Arthur Rawlings, J. T. West, W. Rawlings, Mrs. Gladstone, and Duke of Fife. Middle row: Glow-worm, Mrs. Langtry, Shirley Hibberd, Mrs. Saunders, Lustrous, W. Powell, Rev. J. Goodday, and Mrs. J. Downie. Front row: Prince of Denmark, Crimson Globe, Harrison Weir, Prince Bismarck, Mrs. N. Halls, Frank Pearce, Willie Garratt, and a seedling. Mr. A. Ocock, gardener to Mrs. McIntosh, Havering Park, Romford, was second with fresh even flowers, forming an admirable stand. Mr. T. Hobbs, St. Mark's Road, Easton, Bristol, was third; and Mr. T. Anstiss, Brill, Bucks, fourth.

There were ten stands of twelve blooms, Show varieties only, Mr. Sidney Cooper, The Hamlet, Chippenham, winning with a splendid stand, one of the best, in fact, in the Show. The varieties were Maud Fellowes, Goldfinder, Duchess of Albany (self), Victor, Henry Bond, Harry Keith, Wm. Rawlings, R. T. Rawlings, J. T. West, Mrs. Saunders, T. J. Saltmarsh, and Reliance. Mr. T. Vagg, gardener to J. Theobald, Esq., M.P., The Bedfords, Havering, Romford, was second with smaller but very even neat blooms; Mr. G. Boothroyde, Red Hill, Havant, third; and Mr. Wm. Hopkins, Cross Hands, Pilning, Bristol, fourth. Seven competed with six blooms, Mr. John Cozens, Langley Burrell, Chippenham, winning with Colonist, J. T. West, Victor, John Walker, Mrs. Gladstone, and Picotee in splendid condition; Mr. J. Gilbert, Brooklands, Freshwater, Isle of Wight, was second with neat fresh flowers; Mr. W. Wheeler, 53, Bell Street, Henley-on-Thames, third; and Mr. Jas. Strudwick, Silver Hill, Hastings, fourth.

The class for twelve Fancies brought five stands, the best being a beautiful one from Mr. Sidney Cooper, in which the flowers were in splendid condition. The varieties were Rebecca, Mrs. Downie, Prince Henry, Salamander, Lottie Eckford, Mrs. Saunders, Duchess of Albany, John Cooper, Mandarin, Comedian, Dorothy, and Peacock. Mr. West was second, also with an excellent stand, but several points in the rear of Mr. Cooper. Mr. Ocock was third, and Mr. Mist, Collingwood, Igham, Sevenoaks, fourth. The best of ten stands of six came from Mr. Boothroyde, who showed Matthew Campbell, Rev. J. B. M. Camm, Dorothy, Mrs. Saunders, Frank Pearce, and Comedian in excellent condition. Mr. Vagg was a very good second; J. Gurney Fowler, Esq., Glebelands, South Woodford, third; and Mr. W. Wheeler fourth.

The single variety classes were well filled. Ten competed with six of a dark variety, Mr. Ocock being first with the Rev. J. Goodday, Mr. Humphries second with Arthur Rawlings, and Messrs. Saltmarsh & Son third with W. Rawlings. There were also ten stands of light varieties, yellow excluded. Here Mr. J. Walker, Thame, was first with a beautiful stand of John Walker, Mr. Humphries second with Mrs. Gladstone, and Mr. Seale third with the same variety. There were five stands of yellows, Mr. Seale winning with an excellent stand of R. T. Rawlings, Messrs. Saltmarsh & Son second with the same variety, and Mr. West third. Messrs. Saltmarsh & Son had the best of three stands of tipped flowers, winning with Mrs. Saunders, Mr. Turner second with the same variety. The third prize was not awarded. Mr. Humphries won from four opponents with striped flowers, showing Mrs. John Downie splendidly. Mr. Seale was second with a fine stand of the same variety, and Messrs. Saltmarsh & Son third with Frank Pearce. There were seven stands of edged flowers, Mr. Mortimer being first with Henry Walton, Messrs. Saltmarsh and Son second with J. T. West, and Mr. Arthur Rawlings third.

CACTUS AND DECORATIVE.—Cactus and Decorative varieties in bunches of six made an extremely beautiful display. Messrs. Cheal and Son had a delightful stand of eighteen in the chief trade class, and were placed first, their varieties comprising Lancelot, Robt. Maher, Josephine (new), dark velvety crimson; St. Catherine, Black Prince, Amphion, Mrs. Douglas, Juarez, Harry Freeman, Beauty of Arundel, Charming Bride, Lady Marsham, Marchioness of Bute, Edith Cheal (new), dark velvety crimson; Mrs. Hawkins, Duke of Clarence, Rayon d'Or, and Honoria. Mr. Turner also had a beautiful stand, in which Panthea, Duke of Clarence, Beauty of Brentwood, and Honoria were conspicuous. Messrs. Keynes, Williams & Co. won with twelve varieties, having a splendid stand, albeit the bunches were packed a little too close together. Their varieties were Juarez, Amphion, Miss Violet Morgan (a delicate blush seedling with white centre), Countess of Pembroke, Lancelot, Countess of Radnor, Apollo (a bright crimson scarlet seedling), Duke of Clarence, Mrs. Basham, Bertha Mawley (a brilliant red seedling with carmine suffusion), Countess of Gosford, and one unnamed, apparently Beauty of Brentwood. Messrs. J. Burrell & Co. were second with large flowers, but one or two varieties somewhat past their best, Messrs. Paul & Son, Cheshunt, third, and Mr. M. V. Seale fourth. The class for twelve varieties, Cactus only, was a beautiful and interesting one. Messrs. Keynes, Williams & Co. were first with a delightful stand, composed of Duke of Clarence, Kaiserin, Baron Schröder, St. Catherine, Kynerith, Progress, Delicata, Apollo, Daphne, Countess of Gosford, Bertha Mawley, and Countess of Radnor, lemon, deeply suffused with rosy lilac. Messrs. Cheal & Son were second with Kynerith, Prince Christian, Beauty of Eynsford, and Delicata, very good. Mr. M. V. Seale was third.

Cactus and Decorative varieties were also well shown by the amateurs. Mr. West won with twelve varieties in bunches of six, showing Joseph Chamberlain (a rich scarlet seedling), Baron Schröder, Stebbing Wheeler, Black Prince, Kynerith, Marchioness of Bute, a delicate mauve seedling, Millie Sculpham, Mrs. Douglas, a lemon coloured seedling Mrs. Keith, and Lancelot. Mr. Strudwick had the best of the other two stands, and the third prize fell to Mr. Mist. There were ten stands of six and three blooms of each, Mr. Wm. Hopkins winning with Duke of Clarence, Robert Maher, St. Catherine, Cannell's Favourite, Robert Cannell and Delicata, Robert Cannell being the best ornament of the stand. Mr. Sydney Cooper was second, Mr. Peter Perry, gardener to J. C. Tasker, Esq., Middleton Hall, Brentwood, third, and E. Mawley, Esq., Berkhamstead, fourth. Mr. Osman, South Metropolitan District Schools, Sutton, was the only exhibitor of six varieties in bunches of six for Messrs. Cannell's prize and was placed first for Constance, Mrs. J. Douglas, Jaurezi, Lord Lyndhurst, Lady Marsham, and Germania Nova, the latter a distinct Aster-like flower.

POMPONS.—These were splendidly shown in bunches of ten, twenty-four varieties by Mr. Turner in the nurserymen's section, the flowers being delightfully clear, and not too large. The varieties were Marion, Lady Blanche, Isabel, Mabel, Fairy Tales, Darkness, H. E. Searle, Little Lady, Phoebe, Favourite, Golden Gem, Admiration, Mars, White Aster, Boule d'Or, Ringdove, Whisper, Cupid, E. F. Jungker, Ariel, Gipsy Queen, Amber, and two seedlings. Messrs. Keynes, Williams & Co., were a very close second, their flowers being good in all points; and Messrs. Cheal & Sons third. Mr. Seale had a splendid stand of twelve, showing charming bunches of E. F. Jungker, Grace, Admiration, Red Indian, Favourite, Leila, Isabel, Dora, Phoebe, Whisper, and Lilian. Mr. Humphries had an excellent stand, and was placed second, the remaining award going to Messrs. Burrell & Co.

Pompons in bunches of ten, six varieties, were best shown by Mr. West in the amateurs' section. He was placed first for neat examples

of Tommy Keith, Sunshine, Mary Kirk, Eva, Little Sweetheart, and Gipsy, all seedlings. Mr. Strudwick was a very good second, Mr. Osman third, and Mr. West fourth. Mr. Cooper won from five others in the class for six bunches of six blooms each, with E. F. Jungker, Lorna Doone, Whisper, White Aster, Leila, and Phoebe. Messrs. R. Burgin, Eynesbury, St. Neots; C. Stew, Alveston House Gardens, Addiscombe; and P. Perry, taking the remaining prizes.

SINGLES.—These were bright, fresh, and beautiful, losing nothing by not being very large in size. The first prize in the trade class for twenty-four varieties, in bunches of twelve, went to Messrs. Cheal and Sons, who had a delightful stand, the varieties being Annie Hughes, Lowfield Beauty, White Queen, Jas. Scobie, Mrs. Bowman, W. C. Harvey, Miss Linnaker, Evelyn, Miss Roberts, Amos Perry, Marion Hood, Duke of York, Miss Earnshaw, Cleopatra, Duchess of Fife, Lady Whitehead, Northern Star, Duchess of Albany, Formosa, Lady Helen, Mrs. W. C. Harvey, Victoria, Duchess of Anhalt, and Little Snow White. Mr. Seale was second with a very clean, fresh stand, and Mr. E. F. Such, Maidenhead, third. Mr. Humphries won with twelve, Florrie Fisher, White Queen, Mrs. Barker, Maude, James Scobie, Amos Perry, Miss Ramsbottom, W. C. Harvey, Victoria, Miss Roberts, Duchess of Fife, and Northern Star well representing him. Messrs. Paul & Son, Cheshunt, were a good second.

Singles were not very extensively shown by the amateurs, only two competing with six varieties in bunches of ten, but both were good stands, and that of Mr. T. W. Girdlestone was a beautiful one. The varieties were Annie Hughes, Jack, Yellow Satin, Kitty, Little Snow White, and Florence. Mr. Osman was second. Mr. Mawley won with bunches of six, having Amos Perry, Mrs. J. Coninck, Miss Henshaw, Maimé, Miss Roberts, and Northern Star. Mr. Burgin was second, and Mr. Stew third. Mr. Girdlestone was first with twelve varieties in sixes, the prizes in this class being given by Messrs. Cheal & Sons. He had Marion Terry, Evelyn, Sunningdale White, Mikado, Awdry, Sunningdale Searlet, Yellow Satin, Bessie Hutton, Fred Leslie, Dearcst, Marion Hood, and Leila. Mr. Osman was second.

CERTIFICATED FLOWERS.—First-class certificates were awarded to the following:—Cactus varieties: Countess of Radnor (Keynes, Williams and Co.) lemon, deeply suffused with rosy lilac; Countess of Gosford, pale yellow, suffused with orange, pointed florets; Bertha Mawley, brilliant red, with carmine suffusion, very large, but of good Cactus type; May Pictor (Humphries) clear pale yellow, with pointed florets, large and fine; and Delicata (Ware) soft blush, excellent Cactus type. Singles: Duke of York (Cheal) bright scarlet, smooth, well-rounded bloom of medium size; Sunningdale Searlet (Girdlestone) deep scarlet, even, symmetrical, well-rounded bloom of medium size; Yellow Satin (Girdlestone) clear pale yellow, a beautifully moulded flower; and Kitty (Girdlestone), the basal portion of the petals white, the apical portion deeply suffused with rosy mauve, a charming variety. Pompons: Gipsy Queen (Turner) purplish maroon, flowers not too large; Amber (Turner) amber, deepening to orange in the centre, very neat; Bacchus (Keynes, Williams & Co.) bright crimson scarlet, shapely and neat; and Eva (West) a rosy red seedling, with paler lower florets.

MISCELLANEOUS.—Prominent amongst the miscellaneous exhibits was a superb group of Cactus and Pompon Dahlias from Messrs. H. Cannell & Son, Swanley, which was beautifully set up. Of the former section Marchioness of Bute, Ernest Cannell, Robert Cannell, Mrs. Rolfe, Mrs. Keith, Beauty of Arundel, Professor Baldwin, Pride of Swanley, Glory of Swanley, and Princess Christian were conspicuous. The Swanley firm also had an extensive display of double Begonias delightfully arranged. Amongst these was a beautiful bright crimson seedling well worthy of a name. Messrs. J. Peed & Son, West Norwood, had boxes of Dahlias of the different sections, also a collection of well-grown table plants, and a large bank of various foliage plants. Mr. E. F. Such, Maidenhead, had a collection of Dahlias and miscellaneous hardy flowers. Messrs. J. Cheal & Son had a large collection of Dahlias in different sections, also Begonias and foliage of various ornamental trees. Messrs. Paul & Son, Cheshunt, were represented by a large and brilliant display of Roses and various hardy flowers. Messrs. Pitcher & Manda, Hextable, Swanley, had a group of hardy flowers in which Liliiums figured prominently. Messrs. Reid and Bornemann, Sydenham, had a large mixed group in which Chrysanthemums were freely utilised. Lobelia cardinalis splendens Queen Victoria was used very effectively, its brilliant colour telling well. Mr. T. S. Ware, Tottenham, contributed a very extensive group of Dahlias, comprising single, Pompon, Cactus, and Snow varieties. Delicata, a soft blush Cactus of excellent type, was very beautiful; Oban, buff suffused with rose and salmon is a distinct shade; John Bragg, a very dark and velvety purplish crimson, was also noteworthy. Amongst the Pompons was Mrs. Walter Besant, buff edged with bright purple; and Rose Perry, buff edged with deep rose, both neat flowers.

NATIONAL CHRYSANTHEMUM SOCIETY.

SEPTEMBER 7TH AND 8TH.

THE early meeting of the National Chrysanthemum Society at the Royal Aquarium brought together a fairly extensive and very attractive Show. Early Chrysanthemums were represented in considerable numbers and variety. Dahlias were abundant, and there was an excellent display of Gladioli, which, if not very numerous, were exceedingly good. Special interest was attached to the meeting by reason of Chrysanthemum blooms frozen in ice, and sent from Auckland, New Zealand, by Mr. Earland, being exhibited. They were seedlings that had, we understood, been exhibited in New Zealand in April—a spring month with us, but

an autumn one at the Antipodes. Eight blooms were sent, each being frozen in a large meat tin packed in a stout case. Though one or two were apparently discoloured they were in excellent condition. There were both Japanese and incurved varieties, and the blooms were excellent. There were six varieties, comprising white, rose, and yellow, and they were sent under the names of Tarawera, Lady Bell, Rimutaka, J. J. Kerslake, Tongarire, and Zealandia. The last-named appeared to be a good incurved variety resembling Alfred Salter. So far as could be judged they were good varieties, though not an advance on our leading sorts. It would, no doubt, interest our New Zealand friends if the National Chrysanthemum Society returned the compliment in November by sending a case of good prize blooms of the standard varieties most largely grown in this country.

Turning to the general exhibits there were two groups of Chrysanthemums, any varieties, and the first prize one was that of Mr. Vince, gardener to the London Cemetery Co., Highgate. There was not much variety about it, Madame Desgranges and George Wermig being chiefly employed, but they were judiciously blended, and the group was well finished. Mr. N. Davis, Camberwell, was second with a group somewhat brighter in tone. Messrs. Reid and Bornemann had a handsome group not for competition. The first prize for a collection of cut blooms in bunches went to Mr. R. Owen, Maidenhead, in whose beautiful collection Norbert Puvrez, Canari, Golden Sbah, Golden Shower, J. B. Duvoy, Lyon, Mrs. Burrell, Précoité, and René Chandon de Briailles were very noteworthy. Mr. E. F. Such was second with Early Blush, Goldsmith, Mr. Selby, Golden Fleece, and others very brightly represented. Mr. W. Wells, Earlswood, Redbill was third. Mr. H. Neary, gardener to the Rev. R. W. Powell, Hornsey, won with six plants, the varieties being Madame Desgranges, Mrs. Burrell, Mrs. Hawkins, G. Wermig, and Madame Léon Lassalle; the first three were very good, and Madame Desgranges was a beautiful plant carrying upwards of forty fine blooms.

Mr. Turk, gardener to T. Boney, Esq., Highgate, showed Madame Desgranges splendidly, and was placed first for twelve blooms, Mr. J. Wright, Middle Temple Gardens, being second with smaller but good flowers. Mr. Turk also won with twelve of any other large flowering variety, showing a very fine stand of Mrs. Burrell. Mr. Neary was first with Pompons, having Mrs. Cullingford, Mrs. Davis, Madame Léon Lassalle, Lyon, and Nanum, very good. Miss Debenham, St. Albans, was second, and Mr. Davis third. Mr. Beech, gardener to L. Seligman, Esq., was first for six bunches of Madame Desgranges, and Mr. Wright second; while for six of any of the yellow forms of that variety Mr. Beech won with G. Wermig.

In the principal class for Dahlias, that for sixty varieties, Messrs. Keynes, Williams & Co., Salisbury, were first with very good medium-sized flowers, though perhaps hardly so fresh as those at the Crystal Palace. Jas. Cocker, Matthew Campbell, Duchess of Albany, Thos. Hobbs, Mr. Spofforth, Rebecca, Jas. O'Brien, and Maud Fellowes were a few of the best. Mr. M. V. Seale, Sevenoaks, was second with much smaller blooms, and Messrs. Heath & Son, Cheltenham, third. Messrs. Keynes, Williams & Co., who are very strong this year, also won with thirty-six, Mr. A. Rawlings being second, and Mr. M. V. Seale third. Mr. Humphries won with twenty-four, his flowers being very bright and fresh. Mr. Mortimer, Farnham, was second, and Messrs. Saltmarsh and Son, Chelmsford, third. Mr. Humphries won again with twelve, Messrs. Saltmarsh being second, and Mr. Mortimer third. Mr. Vagg, gardener to J. Theobald, Esq., M.P., won with six. In the amateurs' class for twenty-four Mr. J. T. West was first with an excellent stand, Mr. A. Ocock being second, and Mr. W. Mist third. Messrs. West and Ocock were also first and second for eighteen. With twelve Mr. Vagg won, having a fine stand, J. G. Fowler, Esq., being second, and Mr. G. Arnold third.

Cactus varieties, twelve bunches, were splendidly shown by Messrs. Cheal & Sons, Crawley, and they won somewhat easily, Mr. Seale being second, and Messrs. Burrell & Co., Cambridge, third. Mr. Hopkins was first with six, Messrs. J. T. West and E. Mawley following. Messrs. Cheal & Sons also had a beautiful stand of singles, for which they were placed first. Mr. Seale was second with a delightful stand. Mr. T. W. Girdlestone won with twelve, a beautiful stand, and Mr. Humphries was second, the remaining prize going to Mr. Osman. For six bunches the prizes went to Messrs. Mawley, Osman, and Kendall.

Messrs. Cheal & Son had a very fine stand of twenty-four Pompons, and deservedly received first prize; those for twelve going to Messrs. Humphries, Seale, and Burrell. Mr. West showed best amongst the amateurs; Messrs. Osman and Mist following.

Gladioli were very fine. Mr. Lindsell of Rose-growing fame had a beautiful stand of twelve. Le Vesuve, Atlas, Baroness Burdett Coutts, and Dalila were splendid spikes. He was placed first, and Mr. W. H. Fowler second, the latter also showing remarkably well. The latter also had a large collection, in which there were some excellent spikes; and a grand collection came from Messrs. Burrell & Co.

Messrs. Laing & Sons had a bright display of hardy flowers, several boxes of Roses, and Begonias, also thirty dishes of fruit. Messrs. Keynes, Williams & Co. exhibited a stand of new Cactus Dahlias. Mr. G. Humphries had blooms of his new Dahlia Mary Pictor. Mr. R. Dean contributed a collection of dwarf and French Runner Beans. Messrs. Collins Bros. & Gabriel had a box of Challenger Tomato. Messrs. W. Outbush & Son had a large group of hardy flowers, as also had Messrs. Pitcher & Manda, and Mr. E. F. Such sent a collection of hardy flowers and cut Roses. Mr. Chas. Turner had beautiful stands of seedling Cactus and Pompon Dahlias.

FRUIT FORCING.

Pines.—*Young Stock.*—The nursing and succession plants always present at this time of year, under judicious and suitable management, a healthy and luxurious appearance. This arises from the heat of the days and comparative coolness of the nights, and other beneficial effects of natural agencies, so important in the cultivation of Pines. Such influences, however, are now on the decline, and the weather becomes moister as the sun wanes in power, therefore it is necessary to exercise greater care in the treatment to prevent the growths becoming unhealthfully luxuriant—that is, soft. With this object in view steps should be taken to consolidate the growth by the employment of artificial heat and free ventilation. Plants in a luxuriant condition should have air at 80°, above which ventilate liberally, especially on warm sunny days, always avoiding currents of cold air and sudden depressions of temperature, and closing the house for the day at 80°. Maintain a night temperature of 65°, and 70° to 75° by artificial means in the daytime. The bottom heat should be kept steady at 85° at the base of the pots, or between 80° and 90°. Water only when absolutely necessary, then afford a thorough supply of weak liquid manure warmed to the temperature of the plunging bed. The plants will only need syringing occasionally, and it should be effected early in the afternoon of bright days, and not excessively.

Fruiting Plants.—These must be brought together in a structure suitable for finishing the fruit well. When mixed with succession plants fruiters cannot be given the treatment essential to the proper development and perfecting of the fruit. Those on which the fruit is swelling require a liberal amount of heat and moisture, a night temperature of 70° to 75°, and the heat in the daytime should range from 80° to 90°, closing the house at 85° with sun heat, so as to insure a rise of temperature from that source. Avoid, however, a close and very moist atmosphere, as that accelerates the growth of the crowns, and they are usually quite large enough. Although due supplies of nourishment are needed for the proper swelling of the fruit, it must not be given to excess, or the fruit may when cut be found black in the centre.

Peaches and Nectarines.—*Earliest Forced Trees.*—These have now shed their leaves, and will have some rest before being again started into growth. This is absolutely essential to a good start, the trees forced several years consecutively taking their rest at the proper time, and starting again at the usual period. Such trees are far less costly to force than those which have not been forced to ripen their fruit at an early period. It is, however, necessary that early forced trees be kept perfectly clean and the foliage healthy to the last. Trees that have had their leaves smothered by the webs of red spider and their juice abstracted are practically useless for affording a crop of fruit. The pests always infest forced Peach and Nectarine trees, but we have invariably found that the greatest immunity from their attacks was had by instituting the best preventive measures, and eradicating as far as possible the causes of the infestations. Red spider hibernates in cracks and crannies of the trees and house, beneath clods and stones, anywhere and everywhere that affords a safe retreat. Aphides also live through the winter under favouring conditions, and where those are antagonistic they instinctively deposit eggs on the trees and on those parts near to where growths will be produced that are to form the necessary food for their progeny. Scale insects are much the same, all make provision for the perpetuation of their species. The business of the cultivator is to safeguard the objects of his cultivation against fungoid and insect enemies by such preventive measures as are known to be effectual. Whether it be in the egg or developed state, no insect can endure the old and effectual thorough-cleanliness system. It consists in syringing the trees and house in every part with water at a temperature of 140°. This must be used carefully; if too hot it will injure the trees, and if lower in temperature it is innocuous as regards the insects and their eggs. At the proper temperature it speedily destroys the insects and adds the eggs. In bad infestations the application should be repeated once or twice on different days. Then loosen the trees from the trellis, tie the branches in small bundles for facilitating cleansing operations, and wash the woodwork and ironwork with a brush, soft soap and hot water, reaching every angle and crevice. Limewash the walls, adding a handful of sulphur to each pailful (three gallons) of hot limewash, and if required paint the wood and ironwork. Then prune the trees, this will be a light affair if the instructions given in this column from time to time have been intelligently followed, merely thinning the shoots where too crowded or too weak for carrying fine fruits. No shortening will be required, except on long shoots for the production of growth at the right place for extension. Wash the trees with a solution of soft soap, 4 ozs. to a gallon of water, reaching into every crack, hole, or crevice, taking particular care not to dislocate the buds, yet thoroughly wash every part of the trees. Tie the trees to the trellis, and remember that carefully trained evenly balanced trees are a pleasure to the eyes. Let the ties be such that the branches and shoots have sufficient room to swell. Avoid bruising or injuring the trees in any way, for such may result in gum.

Remove the loose surface soil down to the roots, and supply a couple of inches of fresh loam, strong rather than light. Sprinkle a good handful of the following mixture over each square yard of surface; steamed bone meal, Thomas's phosphate powder, and wood ashes from twigs only, all in equal parts by weight, mixed thoroughly. If wood ashes cannot be obtained (and those from large wood are not nearly so good as the others because they consist mainly of lime) substitute sulphate of potash for them. Leave it on the surface, the rains or waterings will wash the mixture in fast enough, and the soil will hold the elements until the trees push active feeders and are provided with leaves to assimilate them. Avoid heavy top-dressings, especially of crude manure, for they only induce exuberance in the trees and prevent air exercising its beneficent influence on the soil. If the lights have been removed keep them off until the borders are thoroughly moistened by the autumn rains; indeed, they need not be replaced until the time arrives for starting the trees. To have fruit ripe with certainty at the end of April or early in May without hard forcing or prejudice to the health and bearing powers of the trees in consecutive years, they should be started early in December, even when the earliest varieties, such as Alexander and Waterloo Peaches, with Advance Nectarines, are grown, the house being closed a fortnight before applying fire heat, except to exclude frost, so that the trees are gradually excited, and respond to the artificial warmth promptly when it is applied about the middle of December. The varieties named may be forced so as to produce ripe fruit in about three calendar months, but we find it is better for the trees and the grower to allow a month or six weeks more time. If fruit is required very early and in the shortest time possible, it ought to be sought from pot rather than from planted-out trees. Pot trees intended for early forcing ought now to be procured; those that have been grown under glass, have the wood thoroughly ripe, the buds well but not over-developed, and which have not been cropped, or only moderately, are the best. They should be top-dressed, be kept cool, but not dry at the roots, until the time arrives for starting them, or they may be plunged in ashes over the rims of the pots in a sheltered position outdoors.

Second Early-forced Trees.—The introduction of the early varieties has made a difference of a month to six weeks in forcing Peaches and Nectarines in having ripe fruit by a given time. By growing the very early and usual forcing sorts together a succession of fruit may be had from the same house over a lengthened period. If the house is only large enough to accommodate three trees, say Alexander or Waterloo, Hale's Early or Early Louise, Royal George or Stirling Castle (we prefer the last named in each case for certainty of crop and excellence of quality) and the forcing is commenced with the new year, a supply of fruit may be relied on from the close of April or early May to nearly midsummer, without unduly taxing the energies of the trees, or prejudicing their cropping in the future. The trees will now be shedding the leaves, and the buds will not be over-matured if the roof lights were taken off by the middle of August, and such are not likely to cast the buds, whilst those subjected to hot and dry conditions will drop them in a shower later on. When the leaves are all down treat the house and trees the same in every respect as described for the earliest-forced. The roof lights should remain off until the approach of very severe weather, and when replaced admit air to the fullest extent, so as to insure complete rest to the trees. When the roof lights are left off until frost has come and snow has fallen, and the house is locked in ice and snow, it is difficult to replace them, therefore precautionary measures must be taken to prevent delay in starting on account of the weather.

Succession Houses.—Trees that grow too luxuriantly should as soon as the wood is getting rather firm have a trench made one-third the distance from the stem that the trees cover in extent of trellis and quite down to the drainage, so as to detach all roots, and this may be left open a fortnight, then the soil may be removed with a fork down to the roots and picked from amongst them, laying in the roots in fresh material; good strong loam, with a sixth of old mortar rubbish intermixed, being best. Care must be taken that the trees do not suffer from want of water whilst the trench is open, but none need be given unless the foliage becomes limp. This proceeding should be followed by a good watering, and if care has been taken in removing the soil not to disturb the roots to an extent causing the collapse of the foliage, the roots will soon work freely in the new material and the fruits invariably set and stone well afterwards. The taking out of the trench is more especially necessary with young trees, the process being very effectual in counteracting their tendency to late growth and in assisting them to ripen the wood thoroughly. Root-pruning and lifting must be deferred until the leaves give indications of falling, but those operations are best performed as soon as the wood is sufficiently matured and whilst the leaves are upon the trees, yet not so early as to cause their collapse and leave the wood unripe and the buds not plumped.

Late Houses.—These have been favoured upon the whole, the bright weather being particularly suited to the late varieties, which, as a rule, are not the best in colour, though from their wonderful size and delicate appearance they are strikingly beautiful, and when the trees are given proper supplies of water and nourishment during growth the quality is excellent. The trees must still have sufficient water, though a drier condition at the roots is desirable when the fruit is ripening than when it is swelling, but if kept too dry the fruit becomes mealy. A free circulation of air is necessary, utilising sun heat if the fruit is backward, as with ventilation early in the day the temperature may run up to 85° or 90°, which is very much better than fire heat at a later period, increasing as it does the size and appearance of the fruit and enhancing its quality. Keep the wood thin, stop any growing shoots at about

15 inches or to such a length as is likely to become well matured, and pinch all laterals to one joint as growth is made.

Melons.—Plants in pits and frames will not need further damping over the foliage, and they should only be given enough water at the roots to keep the foliage from flagging. Keep the growths rather thin, closely suppress laterals, but retain the principal leaves, and elevate the fruit well above the bed on inverted flower pots, each fruit being placed on a piece of slate, and so inclined that water will not lodge upon it and cause the fruit to decay. Apply good linings to the sides of the frames, so as to furnish a warm atmosphere, kept dry by free ventilation, which the fruit requires to finish well.

The latest plants in houses are now in flower. The blossoms should be fertilised when fully expanded, and attended to daily until sufficient fruits are set for the crop. The atmosphere must be kept dry, a little ventilation being given at night to prevent the deposition of moisture on the flowers. Stop the shoots one joint beyond the fruit, and when the fruit is set keep the growths well in hand, not allowing the laterals to interfere with the principal leaves, exposing all the growths to as much light as possible. When three or four fruits are set on a plant remove all the male and female flowers, and do not overburden the plants with fruit, but thin them so that each will attain perfection, being guided by the vigour of the plants. Supply earth to the sides of the ridges or hillocks as the fruit swells and needs more nourishment. Water carefully, yet encourage and sustain root action by a proper amount of moisture in the soil. Syringing will only be required on fine afternoons, but a genial condition of the atmosphere should be maintained by damping the paths, walls, &c., in the morning and afternoon. Maintain a night temperature of 65° to 70°, and 70° to 75° by day artificially, with 10° to 15° advance from sun heat.

Fruit Ripening.—This should have brisk heat by day, with enough ventilation to insure a circulation of air constantly and abundant increase in the early part of fine days. Keep water from the house and withhold it from the roots, or only supply it to prevent flagging. Plants swelling their fruit to ripen next month must be assisted with tepid liquid manure whenever they become dry, but avoid strong doses, as these are fatal to the roots, and cause the collapse of the plants before the fruit is ripe. Expose the main leaves to all the light possible by stopping, thinning, or removing the laterals. If canker appear rub quicklime into the affected parts and repeat as necessary to arrest its progress, and so keep the plants alive until the fruit is perfected. Free ventilation and a genial warmth are the best safeguard against canker and cracking in the fruits. These evils are accelerated by a close atmosphere and a low night temperature, which cause the deposition of moisture on the stems or fruit.

THE KITCHEN GARDEN.

Tomatoes.—Seldom have the open-air Tomatoes made so good a start as they did this season, and nothing like a check has yet been experienced. Already considerable quantities of fruit have been cut from those well forwarded under glass prior to being planted out, and all have set abundance of later fruit. What we have most to fear now is a sudden attack of Potato disease, a term of dull, damp, warm weather favouring a rapid spread of this. If the foliage could be kept dry even this kind of disease would be warded off, but this is a somewhat difficult matter. In many cases, however, much might be done towards preventing disease by means of spare pit and frame lights, these being fixed over the best cropped plants against walls in anticipation of rather than after an attack. Stripping off the old leaves wholesale is a very common but most unwise proceeding, baring the fruit to strong sunshine, completely checking swelling, and it is very doubtful if it greatly hastens ripening. The strong leaves also serve to protect the fruit somewhat from disease, and that is another good reason why they should be retained. If extra gross some of the leaves may be reduced somewhat, and all side shoots ought to be cut away, the leaders also being stopped. Should disease put in an appearance cut all the fruit that has commenced or is on the point of colouring, and ripen under glass or in a warm kitchen; but it is yet too early to cut the whole of the clusters.

Tomatoes under Glass.—Plenty of strong sunshine and a good circulation of dry air suit Tomatoes well, and the crops have been and are very abundant and good in quality. Fire heat ought to be afforded whenever the days are dull or damp, and it also does good if the pipes are made fairly hot every night, the ventilators being kept partly open, a stagnant atmosphere most favouring the spread of disease. Those trained over a roof trellis are the best for winter fruiting, and directly they are cleared of their summer crops some of them might well be got ready for autumn and winter cropping. If trained thickly remove every other plant and fruit the side shoots that the rest should bear freely. In order to promote a healthy fresh growth remove some of the surface soil, give a good soaking of liquid manure, and then top-dress with a moderately rich compost. Strong young plants, however, usually give the best results, and if these are placed singly in 12-inch pots or small tubs, or are planted out in a narrow ridge of loamy soil, they will grow strongly and quickly commence bearing. A good early start is necessary, as the crops must be well set before the days become very short, consequently it is too late now to sow seed or raise plants from cuttings. Give any that are newly planted plenty of air, fire heat being turned on whenever the fires are started, but avoid closing early and creating a very moist atmosphere or disease may soon have to be reckoned with. Conference and a good selection of Large Red are among the best varieties that can be recommended for winter fruiting.

Seed Potatoes.—It is no uncommon occurrence for these to be

spoilt before the winter arrives. Instead of being left for weeks together mixed in heaps of large and small tubers, this invariably causing premature sprouting, they ought to be kept quite separate and thinly stored. Especially is it necessary that extra care be taken of Ashleafs and other extra early varieties. More often than not too few tubers of these are saved, and the rest greatly weakened by being allowed to sprout several months before planting time. It is the strong first sprout that is wanted on these, and in order to be certain of them attend to the tubers now. Select well-formed medium-sized tubers, and set these on their small or blind ends thickly in trays, storing all where both light and air will reach them, heavily covering only whenever severe frosts are imminent. Avoid the time-honoured custom of green-ing seed tubers, as it is possible for exposed sound tubers to take the disease, though not showing it for a long time afterwards. In most gardens main crop and late Potatoes are still growing strongly, but the second earliest are, in all southern localities at any rate, quite fit for lifting and storing. Neither these nor the later varieties, especially those known to be most susceptible of disease, ought long to be left undug after the skins of the tubers are fairly well set. Leaving them till the haulm is quite dead is likely to end in the loss of a portion, at least, of the crop by disease. Drawing and taking away the haulm answers the same purpose, disease usually being washed down from the haulm to the tubers, and this plan may well be resorted to when it is not possible or convenient to lift and store the crops.

Parsley.—There is never any cessation in the demand for Parsley, and it is of such importance that it is only by taking extra trouble in its production during the winter and spring that much worry is avoided. Cooks must have it, and gardeners must do their best to keep them well supplied. The newer or greatly improved strains are unfortunately much more tender than the old stock, the latter very frequently surviving in cottage gardens when the "double," more highly cultivated forms have been killed outright. If two or three lights in a pit, heated or otherwise, can be devoted to Parsley matters are much simplified, but in most cases what is required has to be wintered in deep boxes or large pots. In each and every case no time should be lost in lifting young roots, trimming off the strong outside leaves, and then packing them 4 inches or rather more apart in rich loamy soil. Stand them in a shady position till recovered from the severe check, but do not house till severe frosts are threatened. More plants might also be bedded in where they can be covered by span-roofed or other frames, handlights, or even benders and mats. Branches of fruit trees sometimes afford just enough protection to save Parsley, and it is advisable, therefore, to either sow some seed under these in the spring, or else to plant out roots now, keeping the latter well watered till active growth recommences.

THE BEE-KEEPER.

APIARIAN NOTES.

BEEES AT THE HEATHER.

It is now three weeks since I left home with my bees, and during that time they have gathered honey on part of two days only, the low temperature and strong winds characteristic of the year preventing them flying and secreting of honey. I left home on the 13th of August amidst torrents of rain and a severe thunderstorm, accompanied with heavy rain and hail, which continued more or less severe for several days, doing much damage to crops; but which, singular to say, we at the moors entirely escaped.

Here on the 29th there were from 12° to 15° of frost, which gave the country a very wintry looking aspect indeed. By midday the rain came on, and by the next morning the flats were completely flooded, and the rivers swollen to an extent rarely experienced. Although there are no rain gauges, by a fair calculation of the flood, and computation of the time and quantity of the rain that fell, together with the rises and falls of the rivers, there could not be less than 6 inches of rainfall in the first twenty-four hours. It has rained almost incessantly for three days without any signs of cessation. My bees are standing upon the second step of the natural embankment of the river, and I hear they were flooded as well as all the ricks in a large meadow. I have been unable to see them, but believe from reports that they are uninjured. The loss to farmers must be great, as many sheep, cattle, and crops have been carried away or destroyed by the flood.

It will be seen from this that it is the reverse of cheering to bee-keepers, and recalls to memory the disastrous years of 1860, 1861, and 1862; as also the subsequent three successive bad years which occurred shortly after, but which I cannot recall accurately.

On the 17th of August we had a "pet" day, on which the bees busied themselves killing their drones, and on the same day all our virgin queens mated, some of them being nearly two months old. One very weak nucleus, situated in a wide space, is now strong with stray bees. On this I may have something to say again. More important to bee-keepers at the present time is

for them to be careful that stocks intended for next year are all provided with young fertile queens, as I find 70 per cent. of last year's queens have been deposed.—A LANARKSHIRE BEE-KEEPER.

APICULTURAL ITEMS.

IN further reference to Messrs. Cowan and Benton, I should like to mention that Mr. Cowan's statement was that "no one, in Europe at any rate, has ever seen or heard of pure Carniolans being yellow." This is the text; he wanted Benton to help him out by admitting he had made a mistake in saying they did so exist. Whether such bees are the true and pure Carniolan type is quite outside the question, which I did not and do not touch upon. In 1888, when the controversy was going on, Benton did not hint at all that he regarded such bees as being impure.

Mr. W. H. Ley, of Easton, near Stamford, had a grand stock of hybrid Punics, though crossed with some hybrid Cyprian drone. He reported them rather difficult to handle, while another hybrid stock, mated with a native British drone, were the quietest bees he has ever seen. Well, after reading what Mr. Cowan said he got nervous and had an accident in taking off the supers, with the result that he crushed some bees, and got the stock quite savage. In his haste he decided that Mr. Cowan was right, and forthwith gave them a dose of brimstone; then wrote to me to ask my opinion, as he had fears of having made a mistake, his other Punics being very gentle. This being the first case in which anyone has reported them bad tempered, I told him he ought to have written me first before destroying them. He now writes me as follows:—"Strange to relate, in the stock I sulphured, although I killed most of the bees, the brood and queen were all right, and on opening them to take honey I found lots of brood hatching and the queen laying, so that now they are a good stock again. They have done so remarkably well that I think I shall try them again." I have been charged with claiming the most wonderful virtues for Punics—too wonderful to be true; but here is a case that caps all. Mr. Cowan says they are "short lived." After this, who shall say they have not "nine lives?" I must investigate the matter, because all my queens live a very long time. Here is a case for Mr. Cowan to investigate on the spot; he will not have so far to go as Africa.

Mr. Cowan must feel highly elated at getting "Old Father Langstroth" to write him on Punic bees. Langstroth was favourably impressed with those he saw, and so was Roots, who was expecting Mr. Cowan's finding someone to send them "direct" at a "moderate price"—i.e., 4s. per queen. When Roots found that the former had failed in his purpose he at once accepted all his statements respecting them; hence it is a case of Roots having read Cowan and Cowan having read Roots. This seems to have taken Father Langstroth in; but he will alter his views with a more extended experience with Punics—that is, if his health will allow him to test them. Is it not remarkable for anyone in America to accept failure as the best credential of reliability?—failure to find any mention of Punic bees in his large library; failure to find anyone who had ever seen a colony at work; failure to learn that his co-Editor had had such bees and spoke favourably of them "from experience;" failure to find such favourable allusion, although he was told to "see June Record;" failure to find Punic bees in Tunis, although he claims to have got to the "very spot" I got them from; failure to get a queen over alive for others to see for themselves; failure to even try these bees at all. I could go on thus and fill a column. I repeat, is it not strange for the word of one who has nothing but failures, mistakes, and unintentional oversights for credentials to be accepted by anyone as reliable?—A HALLAMSHIRE BEE KEEPER.

NUMBER OF BEES TO A POUND. — I was much surprised on writing to an eminent manufacturer of hives in London and asking how many bees there were in a pound, to be informed that they did not know. I took the trouble to count a quarter pound of fresh killed bees, and found that there were 1308 in that weight, so 1 lb. would contain 5232.—C. J.

TRADE CATALOGUES RECEIVED.

Messrs. Barr & Son, King Street, Covent Garden, London.—*Dutch Bulbs and Daffodils.*
Messrs. Bunyard & Co., Maidstone.—*Fruit Trees.*
Messrs. Dobbie & Co., Rothesay, N.B.—*Bulbs, Roses, Fruit Trees, Pansies, and Violas.*
Messrs. Hogg & Robertson, 22, Mary Street, Dublin.—*Bulbs.*
Mr. T. Horsman, 102, Godwin St., Bradford.—*Bulbs, Roses, Fruit Trees.*
Messrs. J. Sharpe & Son, Bardney, Lincs.—*Seed Wheats.*
Messrs. R. H. Vertegans & Co., Chad Valley, Birmingham.—*Hardy Herbaceous and Alpine Plants.*

* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Impatiens Jerdoniae (*F. Walker*).—This plant, which we presume you mean, as we do not know an *Impatiens Jerdoniae*, was introduced to this country from the Neilgherries, a range of mountains in the Madras Presidency of Southern India in 1852.

Apricots under Glass (*Constant Reader*).—Mr. Bunyard did not read a paper on this subject at Chiswick, but simply made a few observations, of which the substance was given in our columns last week. He made no pretence to treat the subject in detail, as that was not practicable under the circumstances.

Scale on Ericas (*D. D.*).—The remedy you have found effectual in freeing Crotons and Ixoras from brown scale—namely, "a thumb-potful of paraffin to a four-gallon can of water"—may be employed for the Ericas, provided you take care not to use too much softsoap, and to keep the petroleum evenly mixed with the soapy solution whilst it is being applied to the plants. It is necessary that the mixture be kept from the roots, and that it be used only on the smooth-leaved varieties. If the hairy-leaved varieties are infested "touch up" the attacked parts with spirits of wine diluted with an equal quantity of water, using a small brush. Methylated spirit is not always safe to use, as it contains spirits of tar (creosote).

Naming Peaches and Nectarines (*W. M. C.*).—Like some other readers, you have overlooked what has appeared on the above subject—namely, that specimens of these fruits alone cannot be named; either leaves must accompany them, cut close from the wood, or young shoots must be sent, and in addition we must be informed whether the flowers of the varieties are large or small. It is by a combination of characters in the fruit, flowers, and leaf glands that varieties can often be identified. As a rule, naming them from fruit alone is mere guess-work, as fruits are changed in appearance by cultural and climatal influences. We are sorry, therefore, we cannot name the fruits you have sent, but should gladly have endeavoured to identify them had you complied with the conditions.

Cineraria maritima (*W. E.*).—This *Cineraria*, you say, is not hardy with you; and such is the case in many places, for this simple reason—the soil is too damp and rich. On dry gravelly soils, and on rockwork, it is hardy; and the way we keep it over the winter is to transplant it in autumn to the foot of a south wall, where we allow it to remain until spring, when we plant in its proper position, and by dividing the large roots obtain sufficient plants to fill the space previously occupied. In some soils and situations *Cineraria maritima* will not live. You may, therefore, take up a few plants and pot them in any light loamy soil, keep sparingly supplied with water, and winter in a dry airy situation in the greenhouse. In February place in a temperature of 55° or 60°, which will encourage the production of side shoots. When these are of sufficient size to make into cuttings of three joints, cut them across transversely below the lowest leaf, and remove it and the next above it, leaving one with the growing point at the top. Insert the cuttings in moist silver sand, and plunge the pot in a bottom heat of from 75° to 80°. Place a bell-glass over the cuttings if the atmosphere of the house is dry, but if it is calm and moist the bell-glass may be dispensed with. Keep the sand moist, but avoid wetting the foliage. If the sand be kept very wet the cuttings will damp off. They will root in a fortnight or three weeks, and may then be potted. Continue them in heat until established; then remove to the greenhouse and gradually harden-off prior to planting-out. These *Cinerarias* may be raised from seed sown in February; but the foliage is not so bright in colour as that produced by cuttings from old plants.

Pear Tree Infested with Slug-worm (*C. T. H.*).—The leaves are attacked by the larvæ, called Slug-worms, of the Pear Sawfly (*Selandria atra* of Stephens and Westwood), (*Tenthredo cerasi* of Linnæus and Curtis), and devour the upper surface of the leaves, consuming the soft parts, leaving only the lower skin of the leaf, veins, and midribs, the whole leaf turning brown or black, and ultimately falling. The larvæ usually commence their attacks about the middle of

August, and prey upon the foliage until October, when they descend to and enter the ground, where they spin an oval cocoon, coated with earth, and from that the sawfly emerges in the following July. Dusting the leaves on the upper side with newly slaked quicklime, repeated once or twice at intervals of about half an hour, completely kills the slug-worms. Another very effectual remedy is to slake a quarter peck of quicklime in a tub, add six gallons of water, stir well, and allow it to stand twenty-four hours, then pour off the clear water. Dissolve 8 ozs. of softsoap in a gallon of boiling water, also steep 2 ozs. of the strongest tobacco in half a gallon of boiling water, cover, let stand until cool, then strain, and add the softsoap solution and the tobacco water to the lime water, mix all together, and apply with a syringe to every part of the trees, especially the upper surface of the leaves. Slug-worm infestations are generally local, and recur year after year. As it is getting late, and some of the pests may have entered the soil from the fallen leaves and passed into the pupæ state, we advise the removal of the soil in winter a few weeks after the leaves are all down, taking it off 3 or 4 inches deep beneath the trees that have been infested, and burning it. Supply fresh soil in place of that removed.

Disease in Scotch Firs (*J. H.*).—One of the growths is very much, and the other to a less extent, infested in the leaves or needles with the mycelium of a fungus (*Peridermium acicolum*, a form of *P. pini*), which has permeated the greater part of the tissues and abstracted the contents of the cells, the whole of the green colouring matter (chlorophyll) being gone. This gives the needles, beneath which part of the fungal filaments exist, a sickly yellow colour. There is nothing discernible outside the epidermal tissues as yet, but the reproductive organs are being pushed from the mycelium, and these will appear as outgrowths through the epidermis of the diseased parts after a time in cylindrical, laterally flattened, or conical form, and called peridia. These outgrowths, about one-tenth of an inch high, and one-twentieth of an inch broad, are formed of a thin layer of cells, and tear unevenly at the tips, setting free several minute, orange-coloured spores. These reproduce the fungus, as well as give the popular name of "red rust" to the parasite. The form described is only found in the needles, and it is believed, from the investigation of Wolff and others, to be only a stage in the life-cycle of another fungus (*Coleosporium senecionis*) commonly found on the leaves and stems of the common Groundsel (*Senecio vulgaris*), and readily distinguishable by the orange spots crowded into irregular patches, or in concentric rings, or scattered over the leaves. The spores of the *Coleosporium* are very minute, orange yellow, nearly round, and covered with fine warts. These spores alighting on the Scotch Fir or Austrian Pine often fail (as they do in experiments) to produce the Fir fungus, but we invariably find it on young trees—always, to our knowledge, under twenty years of age—in pleasure grounds where the ground has been trenched, and in woods a few years after the trees have been planted, the turned up ground, whether by trenching or in making holes, giving rise to Groundsel from seeds that have lain dormant. We have not found the fungus infest trees planted distant from the vicinity of gardens—that is, on the mountains of Wales, and on the North Yorkshire moors. There is no fungus as yet in or beneath the bark, but the attack so far is confined to the leaves, and it should be prevented spreading by removing and burning all the parts that show the disease. The ground in the neighbourhood of the trees should be kept as clear as possible of Groundsel, and Ragwort (*Senecio Jacobææ*) should be excluded from the gardens near Fir plantations, for the *Coleosporium* flourishes on the vigorous *Senecios* of gardens, just the same as the fungus which passes part of its existence on the leaves of various species of *Ribes*, and gives rise to the typical form in *Pinus Strobus*, is most luxuriant on a Black or White Currant bush in gardens. This fungus (*Peridermium Strobi*, of Dr. Klebahn of Bremen) attacks the bark, not the leaves, of the Weymouth Pine, and in this form produces æcidiospores, whilst the uredo and telentospores are borne by the heteræcious species found on *Ribes* leaves in the shape of *Cronartium ribicola*, *Dietr.* This species Dr. Plowright found on July 2nd near King's Lynn in Black and White Currant bushes in the garden of Mr. G. S. Boyes, Oakwood House, which is the first recorded "find" of the species in England.

Names of Fruits.—*Notice.*—Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*S. and M.*).—The Apple is probably the Carlisle Codlin, but no one could be absolutely certain from a solitary fruit.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligature, it being often difficult to separate them when the paper is damp.

(*J. J.*).—The Fern is *Adiantum concinnum*. The Dahlias are attractive, but not of exceptional merit. (*J. W.*).—The dark-leaved plant (No. 3) is grown in a large nursery under the name of *Hæmigraphys colorata*. (*C. W.*).—1, *Calliopsis Drummondii*, the dark one is *atrosanguinea*; 2, *Sphenogyne speciosa*; 3, *Vallota purpurea*.

COVENT GARDEN MARKET.—SEPTEMBER 7TH.

MARKET very flat, indeed, with prices much depressed.

WHEAT SOWING.

To have a full strong plant of Wheat sow early in September, using a pure seed sample of sorts of approved excellence, avoiding all tail corn or inferior seed. The matter is worthy of particular attention and a special effort, any momentary inconvenience caused by it being rewarded by freedom from the anxiety and difficulty of later sowings. Every season there are numerous complaints of unfavourable weather and a bad seed bed from those farmers who put off sowing till October and November. Now the soil is comparatively dry and friable, breaking freely before the drill coulter, and covering the seed if sown broadcast by a turn or two of light harrows. Then it frequently clogs the implements, and it is often most difficult to get the seed well covered, and the work is heavier

and slower. This applies especially to heavy land, and it was through having to sow Wheat extensively in such soil that we first gave close attention to this work. The farm was a large one, all heavy land, with considerably upwards of a hundred acres under Wheat every year; the bailiff was an able man and a good farmer, but given to late sowing, and having matters very much his own way the first season, as it was an outlying farm and we had several others in hand. Wet weather, as usual, set in during October, and the difficulty he had in sowing the whole of the Wheat probably did more to promote early sowing subsequently than anything we could say.

The pity of it is that such lessons of adversity are not turned to better account generally. Witness last season, when the sowing of thousands of acres had to be put off so very late owing to unfavourable weather. Surely sensible men have not forgotten this, but have done and are doing all they can to sow early and to sow well. With attention to this, and really good culture, it is only reasonable to suppose that our Wheat averages would be much higher than they now are. The agricultural produce statistics published by the Board of Agriculture show a Wheat average yield per acre last year for England 31.33 bushels; Wales 23.73; Scotland 36.98; and Ireland 32.34; or 31.30 bushels per acre for the United Kingdom. This average certainly compares favourably with those of former years, but it is much below the 5 quarters or 40 bushels per acre which is so possible and so desirable.

The average for Wales is much below the others; it is always so; yet as affording proof of how much better it might be, Mr. G. Byng Morris of Bridgend, Glamorganshire, wrote recently in the "Agricultural Gazette" of a working farmer who sowed a field in that parish with Wheat in September after lea, and, having dressed it liberally with lime, and driven his sheep on and off it, weather permitting, through the winter to tread and manure it, he grew a crop of sixty bushels (7½ quarters) per acre. He also mentions a crop of seventy bushels an acre in the Fens, another of sixty bushels an acre in Oxfordshire. Of his own Welsh farm he says, "I sowed a field of Wheat last October, and manured subsequently on the surface with 3 cwt. of superphosphate, 2 cwt. of kainit, 1 ton of lime, and seven small loads of quite rotten yard dung per acre, in accordance with Ville's directions. I commenced reaping the crop on August 3rd, and am of opinion that the yield will be sixty bushels per acre." In this opinion he appears to be supported by that of the neighbouring farmers, one of whom pronounced it the finest, and the other as fine a crop of Wheat as he had ever seen. "Yet," says Mr. Morris, "my land would not return the seed without fit manuring and cleaning."

Mention is made of his use of lime with other manures, because though lime undoubtedly forms the basis of a successful Wheat crop, the mistake so frequently made is in trusting to it alone. In his well known work on artificial manures Ville says the four substances most favourable to fertility are nitrogenous matter, calcic phosphate, potash, and lime. He terms this mixture his normal manure, and shows by diagrams how necessary each element of fertility is to produce a full crop. With normal manure the yield per acre was 6108 lbs. of straw and 50½ bushels of grain; with nitrogenous manure, without mineral matter, the yield fell to 3069 lbs. of straw and 22 bushels of grain. With minerals without nitrogen it was only 2643 lbs. of straw and 18 bushels of grain; and without any manure 12 bushels of grain and 2323 lbs. of straw was the result. We have seen some crops of Wheat, Oats, and Beans recently so poor that they evidently came under the no manure category.

Early-sown Wheat is in a mild winter so vigorous in growth that it may be worth while running the sheep over it occasionally when the surface is sufficiently dry. In any case they do it much good in the way of manure. But we prefer drilling in chemical manure with the seed, and in doing so judgment is called for in the selection of manures. For soil that is sound and has had

manure regularly for previous crops, a hundredweight of superphosphate with half that quantity of sulphate of ammonia per acre might suffice for sowing with the seed, following in spring just as active growth begins with a hundredweight per acre of nitrate of soda applied as a top-dressing. For exhausted soil the quantity of superphosphate would be increased to 3 cwt., with the addition of half a hundredweight of muriate of potash instead of kainit, with the sulphate of ammonia. For very early September sowings we have used nitrate of soda with excellent results, seed germination being then so quick that the plant is up and growing freely before there is any risk of loss of nitrogen by heavy rain washing it down to the drains. We prefer it to sulphate of ammonia, which is much slower in action.

WORK ON THE HOME FARM.

Early sown Wheat was reaped and stacked in excellent condition before the third week in August. The work was done in a deliberate and careful manner, the stacks being so well built and thatched that all damp from rainfall is excluded, the stacks standing erect and compact, as all well-built stacks should do. We have seen much overripe corn still uncut, to our regret, because of the risk of heavy loss from such corn being shaken out in the cutting and carting.

The sowing of Rye, winter Oats, and Wheat is now being done as fast as possible. We like to have the whole of this work out of hand as early this month as we can, but cannot always avoid some Wheat sowing in October, as autumnal tillage renders this month one of the busiest of the whole year. Horses must be well fed, and men well cared for, to bear the strain, for we will not have an hour of daylight wasted now, and the only plan is to be up and out with the men at dawn of day. Horses are kept in yards at night off pasture during this busy time, having plenty of second-crop Clover in the racks, with a liberal feed of corn morning and night. With a continuance of fine weather we hope to have most of the land clean, and sown or ridged up for winter by the end of the month. We hear much nonsense about which soil requires ridging in winter and which does not. The matter lies in a nutshell. All soil except that which is light and sandy is the better for winter ridging. We must have air circulation in the soil by deep tillage now; drainage as a means to that end shall have attention later on, for if air circulation in soil is to be free and unchecked, superfluous water must pass from it by filtration and not by attraction and evaporation. The one causes the soil to be open, free, and warm, the other seals it against the air, keeps the temperature low both in and upon the soil, and renders vigorous growth impossible.

The tups are now with the ewes as we like the lambing to begin in January, or upon occasion to finish in that month. Early ewe lambs kept going briskly from the first are strong animals by autumn. Profits from sheep are now so low as only to be possible by the most careful selection, breeding, and management. However low the price falls it must never be forgotten how exceedingly useful the flock is upon the land.

REMARKS.

28th.—Continuous heavy rain from 4.30 A.M. to 9.45 A.M.; generally overcast till noon; bright afternoon and evening.

29th.—Wet early; windy day, with occasional sunshine, and one or two slight showers.

30th.—Overcast early; showers in morning; fine afternoon, with sunshine at times.

31st.—Sunny morning; wet afternoon; fair evening.

1st.—Sunny morning; generally overcast and showery in afternoon.

2nd.—Almost continuous rain from 4.30 A.M. to 2 P.M., then overcast.

3rd.—Bright sunshine till 10 A.M., slight showers about 10.30, then generally sunny again.

A damp week of nearly average temperature, but with breezy intervals. — G. J. SYMONS.

A SHORT time ago I had the pleasure of introducing Mr. Owen Thomas to an inspection of the Manresa Vine, also to its diligent and genial grower, Mr. M. Davis. Seeing that both the Hampton Court Vine and the much larger celebrity at Cumberland Lodge are included in the extensive charge of Her Majesty's gardener at Frogmore and Windsor, it was only natural he would be interested by an examination of the younger giant at Roehampton. Though the crop had been cut at the time of our visit the splendid Vine fully equalled his anticipations, and he congratulated the raiser and grower on the cultural skill displayed in its production. Notwithstanding the references of the eloquent champion of the Speddoch Vine a few weeks ago (page 137, August 18th), it yet remains true that no other man in Britain can point to a Vine of his own raising equal in size, training, and healthy vigour to the triumph of Mr. Davis. The weight of the crop this year was just 1000 lbs., the bunches averaging close on 1¼ lb. each. In colour and finish the Grapes were all that could be desired, and not half a dozen bad berries were removed from the whole crop. Nearly 1800 bunches were cut from the Vine early in the season. It is trained in the most systematic manner under 3825 square feet of glass. This is a natural introduction to the Cumberland Lodge Vine, because the invitation to see it was consequent on the visit to Roehampton.

Readers who are interested in big Vines, and they are many, must not expect any descriptive comparison between the two giants inspected. There is only one thing in common between them. It may appear a strange thing to say, but it is true, that both are cramped from want of room, and it will be a thousand pities if more space is not afforded them. Both Vines are in lean-to houses, easily convertible into span-roofs. The Cumberland Lodge Vine has suffered the most by restriction, for its growths have had to be rigidly suppressed for a century; the Roehampton Vine has only recently filled its allotted space, and the additional Grapes it would bear under another roof would give good interest on the outlay in providing it. In this case the Grapes are grown for sale. Those at Cumberland Lodge are grown for Her Majesty's table.

The extension of the Royal Vine is needed for its invigoration, which means the prolongation of its life. Not that this is in jeopardy; on the contrary the crop is better this season than it has been for the past two or three years, but it is surely desirable to do all that is possible to still further improve the condition of the grand old Vine. All that can be done by cultural skill in the present house is being done, as it has been done in the past, and we may be sure there will be no cessation of effort in seeking the production of roots; but no stimulus to root action equals branch extension, and there cannot be a doubt that if the Vine had been provided with another roof to cover it some years ago, its strength and fruit-producing power would have been materially increased. No one knows this better than Mr. Thomas does, for experience has taught him that thousands of Vines are crippled, and the crops weakened, by the constant and rigid suppression of the growths over a series of years. He was quick to see this at Roehampton, and certainly the crop on rods trained in the orthodox way, and restricted to the length of the rafters, was not half so good, nor the growth half so vigorous, as that on rods of the big Vine extending some

200 feet, and the larger these became, the better the Grapes appeared to be.

The Royal Vine at Cumberland Lodge covers the roof of a house 138 feet long by 20 feet wide, except a little at one end where a branch died, but young canes are fast extending over the space, and are the best in the house; they show what the Vine needs—more liberty. The roof was black with Grapes, there being 2000 bunches in finish and quality as good as Black Hamburgh Grapes could be, though not large. The crop appears to be much the same as that of 1879, described by Mr. Barron in his excellent work, as "2000 bunches of an average weight of three-quarters of a pound, or a total of 1500 lbs. of Grapes." This year's crop, though the same in number of bunches, will not, presumably, equal that weight; and it is doubtful if it is in the power of man to maintain the yield in its present area. Significant words are uttered by Mr. Barron in the new and cheap edition of his book just published, a work which all persons who are growing Grapes or trying to grow them should possess. They are cited as having a distinct bearing on the subject in hand. "The principle of extension," he says, "is more consonant with the nature of the Vine than that of repression. Extension is assuredly favourable to longevity, whereas the opposite treatment more rapidly uses up the energy of the plant. The more a Vine is allowed to grow the greater the amount of vital force it secures; were it not that the Vine is an exceedingly good tempered subject, and quickly recuperative, this result would become more generally apparent than it now is. Rich feeding with restricted growth will lead to the production of heavy crops of fine fruit, but it is a high pressure system of management, and it is seldom long before Vines break down under it, and lapse into a condition of mediocrity."*

The volume contains an illustration of a portion of the Cumberland Lodge Vine. It is established about the centre of the house, the trunk being about 4 feet in circumference in the thickest part. It divides into four main branches varying from 18 inches to 2 feet in circumference at the base, these extending and dividing in all directions. In some parts the rods are so twisted and curled as to afford some little surprise that the sap can flow so freely through them as it does. No attempt whatever was made when the canes were tractable generations ago to keep them straight. They appear to have grown as they liked or could, sometimes upwards, sometimes downwards, sometimes appearing to have met with an impediment and doubled back again; yet the old Vine has gone steadily on through the reigns of monarch after monarch, yielding its fruit, like the "good tempered subject" Mr. Barron describes. It is because of its irregularity of growth, the laterals being trained where there is room for them, and in any direction, that all comparison fails between this and the Manresa Vine. They bear the same relation to each other that a beautifully trained Pear tree on a wall does to a huge orchard standard left to assume its natural habit. The Cumberland Lodge Vine has been dressed by many hands during its long career—it is supposed of about a century and a half—but the Roehampton youngster has scarcely been touched, and probably never pruned except by the hands that made and inserted the cutting. They are both grand Vines, but grand in different ways. One is representative of ancient practice, the other of modern methods, but not too modern. Though the Royal Vine is like the nation, old, we will hope that, also like the nation, it will have liberty to extend its arms and gain strength by such extension; then will future generations know that it was cherished and well tended during the reign of the great and good Queen Victoria, who will, as all who read these lines sincerely hope, for many years to come enjoy its luscious fruit.

In connection with the visit a glimpse was had of the extensive

* "Vines and Vine Culture," third edition, 5s., by post 5s. 6d.: 171, Fleet Street, London.

gardens at Frogmore, and of the beautiful terrace gardens at Windsor. Frogmore is a great supply establishment, five or six men being constantly employed in gathering and packing produce for the Castle, Balmoral, Osborne, or wherever the Court may be. The kitchen garden ground is nearly 50 acres in extent, and every part as clean and orderly as a well-kept villa garden. The aggregate length of rows of one sowing of Peas was just a mile, and other crops are grown on a proportionately large scale; 11 acres are devoted to Potatoes, Asparagus, Seakale; and even Horseradish are grown by the acre. The walks are margined by Lothian Stocks—fine bushes, 2 feet high and through, from seed sown in February.

On the walls the Peach crop is a magnificent one, hundreds of dozens of fruit having been gathered with plenty more to follow. On the walks are 2000 Chrysanthemums admirably grown, mostly for producing large blooms, and many buds are set; but several plants are grown as bushes for supplying armfuls of cut flowers, while a few hundreds of hardy little plants for decorative purposes are coming on from cuttings inserted early in August. Of Strawberries, 10,000 are established in pots for forcing, some with huge crowns, others not long placed in their fruiting pots. La Grosse Sucrée is preferred to all other varieties. Good work is being done under glass. Vines are in various stages, the roof lights are off the early houses, and the Vines ready for pruning. Several houses have been planted with young Vines, which have made excellent and firm growth. Mr. Thomas is no believer in the wild system of unrestricted growth in summer to be cut away by yards in the autumn, and he tops young Vines when he thinks they have gone far enough. That he will have fine Grapes is certain; and he is almost certain to work on the steady extension system.

Very good crops of Grapes are hanging on established Vines, and in one house especially the beneficial effects of a change in pruning is very striking. The Vines had been closely spurred for years, with the result that the growth became weaker and the crop lighter. The laterals were shortened to the best eyes on ripe wood from 3 to 6 inches from the rods, and the house was filled with good Grapes, the crop being quadrupled in a season. Amongst them is a seedling of the Lady Downe's type, though much finer, but its quality and keeping value remain to be tested.

The Pines for which Frogmore has long been famed, planted in 2 feet of soil on beds of 6 feet of leaves in Dutch pits, are in splendid condition and supporting magnificent fruit. Successional plants from suckers planted in April have made marvellous progress, the plants reminding of Yuccas by their broad thick leaves. Massive fruits may be expected from them next year, and the reputation of the Royal Gardens in this department will be sustained. Melons are grown in hundreds—enough for a town, one would think, and something like a town has to be supplied, for when the majestic old castle is full, the demand for all kinds of produce is enormous. A glance was cast across the terrace garden, in which bright and sweet flowers are charmingly associated with choice Conifers and ornamental shrubs. The combination is a delightful one and possibly unique.

Mr. Thomas has been long enough to get a firm grip of his duties and to prove himself master of his great charge. He is loyally supported by permanent departmental foremen, of whom he speaks highly; they will find in him a chief as just as he is able, and the fair fame of the Royal Gardens is safe in his keeping.—J. WRIGHT.

P.S.—I have to revert to the Manresa Vine, to give Mr. Cannell of Swanley the credit to which he is entitled. He is the real author of the famous Vine. Thirty-five years ago he was engaged in a public discussion, and it was because his arguments in favour of extension appeared stronger than those of his opponent against it—at least to Mr. Davis—that he determined to try the plan on the first opportunity, and this occurred at Roehampton. Mr. Davis stated this to Mr. Thomas and myself at our recent visit, and it is only fair to the Swanley original—for an "original"

he is—that the fact should be recorded. Mr. Davis not only raised the Vine, but built the house and glazed its 3584 square feet of roof with his own hands. Mr. Cannell should go to see his disciple.—J. W.

THE ROCK GARDEN.

(Concluded from page 97.)

THE Saxifrages, Sempervivums, and Sedums form a very numerous group of plants of the most varied forms and characters, many of which are admirably adapted for the rockery; indeed, I once remember seeing in the North of England a rock garden in which the plants were almost exclusively of these groups, and a very pretty rockery it was; but while few will be inclined to imitate this, there is no one who has a rockery that does not feel himself indebted to these plants for many an adornment to it. Although there may be some more "coy to please" than others, yet, as a rule, they are easily grown; they are amongst the very earliest flowers to bloom, for Saxifraga Burseriana comes even before the Snowdrop, and from these a long succession of plants, pretty in foliage and in flower, follow on for several months. In a small garden like mine one cannot indulge in the luxury of growing all or anything like all of these plants, and I have, therefore, made a selection of a few of the best.

Saxifraga Burseriana.—Nothing can be neater than this pretty but slow growing species, its "hedgehog-like" rosettes being covered in early spring with large white flowers on bright red flower stems. These are produced so abundantly that they completely hide the foliage. The variety major is larger.

Saxifraga lantescana.—A fine rosette, sending up large panicles of white blooms, closely resembling pyramidalis.

Saxifraga Macnabiana.—A charming plant with panicles of white flowers, beautifully spotted, and marked with carmine.

Saxifraga longifolia vera.—This great Pyrenean Saxifrage has been called, and not undeservedly, the queen of Saxifrages. I have had it many times, and it has grown and flowered well, but unfortunately its habit is to die after this, bearing no offsets—at least, I have never found any, so that it has to be constantly raised from seed. By far the finest lot of plants I have ever seen were at the Millmead Nursery, Guildford. There was a bed of them containing hundreds of plants, which had all been imported from the Pyrenees—plants measuring 15 to 18 inches across, and all in most vigorous health. Their appearance was a treat indeed, and disposed of the idea, which had always been stated by growers, that it required to be planted on a slope in the rockery, for it is evident that, like Ramondia from the same region, it will do on level ground equally well. Probably it is generally found in this position, and hence it has been supposed that it was necessary to imitate Nature in the garden. There is this, however, to be said in favour of planting it laterally—that you see the beautiful rosette of foliage to much greater perfection. It is extremely hardy; no amount of frost seems to have any effect upon it.

Saxifraga oppositifolia.—This charming dwarf Saxifrage is one that for a long time puzzled me. I tried it in various situations and on various soils, but to no purpose, and yet everybody told me it was amongst those plants that "duffers" could grow, so that I was worse than a duffer. At last I tried it on a small rockery, just under my study window, and there it has done admirably, and it is certainly one of the most delightful of our early spring flowers. Where it has freer scope than it has with me I have seen it clothing rocks and stones with its pretty close foliage. The variety alba is also very pretty, and there have been some varieties introduced which are more desirable even than the type, the flowers being larger, and also produced in greater abundance. Of these pyrenaica, introduced by Mr. Backhouse, and splendens are perhaps the most desirable. Of the Mossy Saxifrages perhaps the prettiest, both in its large cushions of mossy looking foliage and its bright flowers, is atro-purpurea; it thrives, too, in almost any situation on the rockery, and increases very rapidly; its brilliant starry red flowers set on their soft cushions of moss make it a very attractive object.

Sempervivums.—Of these I have only grown two or three of the most distinct kinds. Arachnoideum is well known for its curious spider's web-like filaments, which spread from point to point of its charming rosettes. It is best grown in poor soil, and with a quantity of broken stones, or in the crevice between two pieces of rock. It will bear any amount of fierce sunlight, for I have seen it in chinks of rocks in the very hottest place in the "Mauvais Pas," near Chamounix, where one would think it could not have found any soil to root in. Our wet autumns and winters, although they do not kill the plant, take away a great deal from its beauty, washing off to a large extent the delicate web-like structure, and it is, therefore, one of those plants which will be all the better for a piece of glass over it in the winter.

Soldanellas.—These form a class of those alpine gems which so often puzzle the cultivator. There is no difficulty, or at least very little, in getting them to grow, nor is it needful for this purpose that they should be planted in a bog, although they like a damp situation. I have had them for many years, and only once did I get them to bloom except when in pots, and this is a kind of culture I do not care for. They are very curious little plants, not showy but quaint, with the fringed edge to their petals.

Shortia galacifolia.—I cannot say much about this pretty North American plant, which has been recently introduced, or perhaps I should say, reintroduced, amongst us, for although I have it on the rockery, where it seems as if it would establish itself, yet, as in most of these new things, it is a very small bit, and I do not look for any bloom until next year.

Thymus lanuginosus.—This, and others of the same fragrant alpine, are very dwarf and neat habited; they come into bloom, too, when a great many of the alpine are over. They form also excellent carpet plants, as most plants push their way through the dwarf growth very readily. They are plants, too, which increase so rapidly that there is constant need of rooting out a good deal of them.

Trillium grandiflorum.—This curious and beautiful North American bulb rejoices in a damp and boggy position, but it is not absolutely necessary for it, as I have seen it in some places doing well in the open borders, but in its native habitat it loves the borders of woods in swampy places, and where that situation can be imitated it will be the best for it. I cannot do this, and it has to content itself with a piece of damp peaty soil, and there it does well. It had at one time the protection of a small bush of *Menziesia*, but this succumbed to the severe winter of 1890, and it still seems to get on quite well.

Veronicas.—Of this numerous genus, so many of which are shrubby and hardwooded plants, the most useful for the rock garden is *Veronica repens*, a miniature form, which hides with its dense and dwarf foliage all the surface of the ground where it is planted, and covers itself in early summer with a profusion of deep purplish blue flowers, very deep in colour. This and its near connection *rupestris*, are admirable plants for quickly covering a space, and will not interfere with the growth of many plants.

In bringing these notes to a conclusion I can only repeat what I have already said, that there are many plants which, however beautiful in themselves, are confessedly difficult of cultivation, and therefore I have not broken my heart over them. I have not that ambition (more's the pity!) of succeeding where others have failed. I leave this to other and more skilful hands. I have merely brought under notice those which I myself have grown, and which, therefore, I can assert anyone may grow with ordinary attention. As I have stated, the rock garden will accommodate a good many guests, for literally hundreds of species of plants may be grown upon one even of moderate proportions. The chief beauty of the alpine garden is in early spring, and its characteristic is not so much brilliancy as quiet, chaste beauty; its tones are not those which attract by their brightness, but by their harmonious blendings with their surroundings when spring creeps on to early summer. Although some of its denizens still remain to greet us its glory is gone, and we have then to turn to the herbaceous border for the brilliancy and grandeur of form which are to be our chief enjoyment during the summer months. The charming little *Scillas*, *Chionodoxas*, *Primulas*, &c., give place to *Delphiniums*, *Spiræas*, *Lilies*, and other fine growing and stately plants, all beautiful in their way, but all essentially different from the variety which enchanted us in early spring, and for these reasons the growth of the alpine plants is well deserving of more attention, and, let me add, brings one into contact with many whom it is a pleasure and delight to meet. There are men who have gone about a good deal who could tell you many a story of their wanderings in search of their pets, and then there is the additional pleasure of being able to give to others what you yourself have obtained. These are surely sufficient reasons why all who love a garden should seek to establish a rockery.—D., Deal.

NOTES ON TOMATOES.

IN visiting several Tomato establishments it was very satisfactory to find that upon the whole the traces of disease were very slight, although no place was entirely free of it. The establishment of the cousins Buchanan was the most extensive of those visited. Besides the houses formerly erected, which are being converted into peacheries and vineries, they erected during the past spring six additional structures, each 130 feet long, built in threes, ridge and furrow. The centre ones are 16 feet wide, and the outside ones 12 feet. The six houses cover a superficial area of 10,400 feet, and are to be devoted to Tomatoes. The plants in

the old houses are looking well, and carrying a good crop. These in the new houses are late, but if the autumn is fine they, too, will produce a good crop. Altogether things are looking very encouraging with them in that out-of-the-way, dreary spot, Cauldham, Kippin.

My own crop is very good, but as for varieties they require to be restricted. Prelude is too small if one wants the top price. It has a fine sturdy habit, and is very prolific; I have counted as many as forty-seven fruits on 3 feet of stem. I have crossed two or three of the large fruiting varieties with it, from which I expect to get something good. The fruit is very round, in compact trusses, and of good colour. I have two varieties of it. One has red fruit and small foliage, the other has large and dense foliage, with a pinkish purple fruit. Eclipse (Austin's) is one of our sheet anchors. The fruit is of good size, globular, rather deep than broad, sets freely; the truss is compact, and bears from four to eight good sized fruits; the foliage is lax. Ham Green Favourite has a medium sized fruit of good colour, but the truss is weak and very straggling, dividing into several branchlets. Northern Beauty (Dickson, Brown, & Tait's) very much resembles a selection I have from Ham Green. The fruit is deeper than the type and darker green in colour when young. Perfection (Carter's) belongs to the large-fruited section; the foliage rather dense. It is not a free setter, and is apt to show a large scar where the flower has been. I got a packet of Clibran's Tomato from the introducers, in which there was more than one distinct variety. What I take to be the true one is of the large section, resembling Perfection very much in shape of fruit, but not so subject to show the large central scar; the foliage is more elongated, the trusses strong and compact, carrying three to five fruits. Altogether it is a desirable variety. Plentiful, introduced during the past spring by Messrs. Sharpe of Sleaford, is a good all-round Tomato of the large section, very pleasant to eat.

The solidest and the one which I consider the best in flavour and appearance is a seedling raised this season from a fruit of the Jersey Vinery Company's Tomato, which I picked out of a basket last season. All those planted are the true variety except this one. It is so solid that fruits of quarter-pound weight have not produced more than fifty seeds. If in another season it comes true to the original I will send some fruits for your inspection. I send you two diseased fruits. When the disease shows first it has the appearance of Grapes when scalded; the skin loses its vitality, and the flesh, particularly among the seeds, assumes a black colour. I have failed to trace any appearance of fungi upon the skin, therefore think it must arise from something within. When saving seed I have often observed some with a black spot upon them. May not these seeds with the black spots be the centre of the disease? Eclipse is the most subject to it, although Ham Green and Northern Beauty are not clear.—G. McDougall, Stirling, N.B.

WALLFLOWERS IN POTS.

THESE popular and exquisitely scented flowers are not so much grown in pots as they deserve to be. Possibly the reason for this is that they are considered common. Yet notwithstanding this, I believe a good batch of plants in flower during the early spring months would be a welcome addition to any garden where they have not been previously grown in pots. In establishments where large cool conservatories have to be kept gay they are especially valuable, not alone on account of their bright colours and sweet perfume, but also because when the flowering period is over they may be consigned to the rubbish heap, and thus make room for other plants at a time when pressure for space under glass is at its height. I consider that the yellow varieties are far the best for pot work, because they supply flowers of a colour which is generally scarce, yet much needed during early spring. Cinerarias and forced bulbs are then in full beauty; in both these classes of plants blue and purple flowers predominate, and the effect produced by arranging among them a few dozen plants bearing bright yellow flowers may be so easily imagined as to need no description.

From the present time till the end of the month is a capital period during which to place the plants into their flowering pots. Those which have been grown in the reserve garden for spring bedding should now be bushy plants in just the right condition for lifting. The requisite number should be taken up carefully with a trowel and placed in 5, 6, and 7-inch pots. The first two sizes will need no other drainage than is afforded by placing a single potsherd over the hole, and covering it with a good thickness of Mushroom bed refuse; but the 7-inch pots should have a layer of smaller crocks placed over the one at the bottom. Very little soil will require to be added as the potting proceeds, for there is generally quite as much adhering to the roots as can be pressed into the pots used, with the exception of the little necessary to

finish off the surface. Fairly good garden soil enriched with Mushroom manure answers this purpose well.

After potting the best position for the plants is behind a north wall, where they should receive a good watering through a rose, and should the weather prove bright be syringed once a day till established. As soon as sharp frosts are anticipated as many plants as room can be found for should be placed in cold pits and the remainder plunged in ashes over the rim of the pots in the open air. By the time the bulk of the Chrysanthemums have done flowering there is generally a considerable amount of space available in cool houses, so that the whole batch of Wallflowers may be given more or less favourable positions, where they will come into flower a few weeks earlier than plants in the open air. There are few subjects which give so great a return in beautiful and scented blossoms for the small amount of labour involved in their culture.

Liberal watering with liquid manure or applications of the many good artificial manures advertised add greatly to the size of the flowers and give them a more vivid colour. The best varieties for the purpose are Veitch's Selected Yellow, Belvoir Castle, and Golden Tom Thumb.—H. DUNKIN.

DWARF PERENNIAL PHLOXES.

PHLOXES that need no stakes, that form compact bushes a foot or very little more in height, and that bear dense heads of flowers fully equalling in size, brilliancy, and diversity of colouring the varieties of the ordinary decussata type commend themselves to more than casual attention. Of such there are now many flowering profusely in the gardens of the Royal Horticultural Society at Chiswick. They have come from various quarters, but the majority are probably of French extraction, and Lemoine may be mentioned as prominent among those who have experimented with such gratifying results on a class of plants that are admittedly of great value. It would be well if the good points of the race could be indicated without throwing any disparagement upon those of the taller type, for these have done, and probably will continue to do, good service; but the differing characteristics of the two classes can only be made clear by direct comparisons. Bold and beautiful as are the tall varieties, they possess a distinct disadvantage in the necessity they impose for free staking ere they can be considered safe from the effects of wind and storm, and a still greater one in their aptitude to become bare and unsightly at the base, necessitating their association with other plants of lower growth before a completely satisfactory effect can be said to have been achieved. Many will have admired the noble effect of large groups when they are seen lifting their huge clusters above dwarfer plants in mixed borders; but when there are no such companions their beauty is frequently marred by an unsightly base. It is as though the effect of an irreproachable coat and a glossy hat were discounted by a pair of seamy and weather-worn boots.

In a select gathering of such dwarf Phloxes as those at Chiswick there is not only perfect beauty of blossom but abundant leafage to the surface of the soil. The plants vie, in fact, with the nana compacta section of the annual Phloxes, of which a good strain is admittedly far superior to the old Drummondii type. They average a foot in diameter, and that or a little more in height. All are floriferous in a marked degree, although in some the inflorescence is scattered, while in others it is gathered in large heads. The flowers vary somewhat in size, but the majority are about as large as a florin, and their wide range of colouring leaves little to be desired. Some of the varieties are selfs, such as rose, carmine, and mauve; others are oculated like Verbenas, or like the best varieties of the annual Phloxes, and these are certainly not the least beautiful. That they would form magnificent groups is well demonstrated at Chiswick, and moreover they would be quite capable of relying for effect on their own resources, not requiring the co-operation of companion plants to hide defects. No staking whatever is required for the dwarfest of them; they no more need support than a Zonal Pelargonium; and for the tallest, which run to 1½ foot in height, one slender stake is ample.

The Phloxes at Chiswick are grown in a series of mixed beds—that is to say, tall and dwarf are associated together. This, though perhaps not so intended, affords the needed comparison between the habits of the plants, and the dwarf compact growers can be picked out readily in passing along the beds, their lowly stature being accentuated by the greater altitude of the “big brothers” beside them. Many of the latter are extremely beautiful as varieties, and their high merit is borne witness to by the three marks which many of them have earned; but those to which brief reference are now made range only from 12 to 18 inches high, the majority being nearer the former than the latter figure. Faust (Lemoine) stands out conspicuously as one of the best and most

beautiful of the collection. It does not exceed 1 foot in height, and is remarkably sturdy, carrying a profusion of oculated flowers, these being white, with a faint rose centre, and of the largest size. Bournouf (Lemoine) is somewhat taller, approaching 1½ foot, but is compact, and its flowers are of a most brilliant red hue. Croix de Sud (Forbes) is another extremely beautiful oculated variety, the flowers being white, with a bold and clearly defined eye of rich rosy crimson. They are large, and freely produced. The height is about 1 foot, and the habit bushy, decidedly one of the best. Eugène Danganvilliers (Forbes) is about 1 foot high, the flowers being pale mauve, and borne with great freedom. Roi des Rosiers (Forbes) somewhat belies its proud title, for the colour is mauve, with a rosy suffusion rather than pure rose, but it is an admirable variety all the same, for its height does not exceed 1 foot; the flowers are numerous, and the colour is eminently pleasing. Bayard (Forbes) 1 foot, may be described as a bright rose, and is a good representative of this rich and effective hue. Le Soleil (Forbes) 1 foot, rich rose, with white centre, is another most beautiful variety. Jeanne d'Arc (Forbes) is useful as a pure white, and the flowers, though small, are abundant. Hirondelle (Forbes) is distinct and beautiful, the colour being of the most brilliant rose, with a deeper eye. Pluton (Forbes) 1½ foot, is a deep glowing crimson, and very free. Felibvre (Dickson) 1 foot, is a rich carmine, and the flowers are abundantly produced. Henri Murger (Lemoine) 1 foot, is white, or rather white with a tendency to lemon, and has a rich crimson eye; the flowers very large. Nain Bébé (Forbes) 1 foot, is rich carmine.

While it would be regrettable if the utilisation of the tall section for positions to which they are specially adapted should become limited, there are undoubtedly others in which they might give way with advantage to the dwarfer sorts. It would be well if the latter could be collected into a group by themselves, and considered as a distinct class of material. It is certain that beautiful effects could be secured by grouping them in beds, and their value would not be lessened by the fact of their beauty developing when that of the great majority of summer flowers is on the wane. The colours of many are so brilliant that few other arrangements could exceed them in richness, while any tendency to garishness could be toned down by a judicious contrast with the more refined hues of the oculated flowers. Small groups would be effective, too, in mixed borders.

When autumn approaches perennial Phloxes are the glory of many suburban gardens, raising their huge clusters aloft in generous profusion; but they often present their best aspect to the passer-by. Were their places taken by select dwarfer varieties, the loss of the outsider would be the gain of the grower.—W. P. WRIGHT.

CASSIA CORYMBOSA.

CONSIDERING that this beautiful greenhouse plant has been in cultivation for nearly a hundred years it is surprising that it is not more often met with, for there are few plants more easily grown or which more richly reward the cultivator. Grown as standards in large pots or tubs they are truly magnificent objects for large conservatory decoration through August and September, a time when flowering plants are not too plentiful.

September is a good time to root cuttings of this plant if intended to be grown into standards, as then by keeping them growing through the winter months in a warm greenhouse, the stem will attain the required height, and with proper attention a good head can be formed that will flower the following August. The details of culture are few and simple, but they must be attended to, otherwise the cultivator will only secure strong flowerless shoots. This can be prevented by constantly pinching back the strongest growths until the head has become sufficiently dense and symmetrical. If possible the last stopping should take place early in May, and when the shoots have again started freely into growth, which will be early in June, the plants should be stood out of doors in a sheltered place. This will induce a sturdy short-jointed growth that will be crowded with flower buds early in August, and this, combined with constantly stopping the young shoots until May, is really the only secret of inducing the plant to flower freely in pots. When the flowers begin to open the plant should be accorded a light place in the conservatory, where they will continue objects of beauty for at least two months.

The flowers are of a bright cheerful yellow, and disposed in numerous corymbs along the upper ends of the young shoots. The plants thrive in three parts fibry loam to one part each of leaf mould, old Mushroom bed refuse, and sand.

After flowering they should be gradually dried off and be stored out of the way of frost in the same manner as Fuchsias. Before starting into growth in early spring, all the branches that form the head should be cut boldly in at from 4 inches to 8 inches

of the crown, care being taken to cut so as to lay the foundation of a large globular head. In all subsequent spring prunings the main branches should be cut back to within two joints of the previous

size pot, and in this way plants may be kept in vigorous health for many years.

I have been induced to enter somewhat minutely into the culti-

FIG. 32.—CASSIA CORYMBOSA.

year's pruning. After well soaking the old ball of soil turn the plant out of its pot, and with a sharp suitable implement cut off 3 inches all round the ball, and 3 inches off the bottom above the drainage. This will allow of the plant being placed into the same

vation of this Cassia from remarks made by a correspondent a few weeks since, in which he hinted that it would not flower satisfactorily in pots. If grown in the way described above it will be found to flower profusely, both as bushes and standards.—J. H. W.

SHOW SCHEDULES.

SCHEDULES have been received of the shows organized by the Birkenhead and Wirral Horticultural Association and the Finchley Chrysanthemum Society. The former is fixed for November 10th and 11th, the latter for November 10th.

MESSRS. W. & G. DROVER'S COLLECTION.

HAVING been staying at Southsea recently, I thought, being in their immediate neighbourhood, I would pay a visit to the celebrated Chrysanthemum growers Messrs. W. & G. Drover at Fareham, and accordingly took an early train to that neat and exceptionally clean little town. On arriving I had no difficulty in finding the nurseries, and received a cordial welcome from the firm. Thinking that as the season for this beautiful flower is now so rapidly approaching a few particulars of my visit would be acceptable to those of your readers who are, like myself, interested in the growth and development of this plant I append them.

On entering the gate of the nurseries a walk of Chrysanthemum plants was right in front of me, all looking in the best possible condition and with wood in many cases as large as an ordinary walking-stick. This long line consisted wholly of Japanese varieties, of which I took special notice of Mrs. S. Dibbens, undoubtedly the best grower in the whole collection. It was about 3 feet 6 inches in height, with large leathery foliage, and carrying three very promising buds on each plant. Middle M. Hoste is very similar, but a trifle taller. Mrs. F. Jameson is of noble strength, about 4 feet high, and carrying three buds each. There is a grand lot of Viviani Morel, about 5 feet high, with very good buds, also Puritan, Sunflower, Etoile de Lyon, and its sport Miss L. Cope, Florence Davis (by this firm considered the finest white of true Japanese form), standing about 6 feet, and some older varieties, such as Condor, Lady Lawrence, M. E. A. Carrière, and Stanstead Surprise, all with good foliage and well set buds, standing about 8 feet high.

Of the incurved section I found most noticeable the Princess family (with the two new sports May Tomlin and Richard Parker). These are all in one row, are about 7 feet high with good wood and foliage and buds just taken. The Queen family this season are not so tall as last year, but are very short jointed and give every promise of good blooms. The Teck family are looking uncommonly well, in fact could not look better. Prince Alfred and Lord Wolseley are carrying splendid foliage with good sized wood and buds just showing. I could enlarge greatly upon this excellent collection but must not trespass too much upon your valuable space. I will conclude with a reference to the hairy varieties principally, Mrs. Alpheus Hardy having good strong, well ripened wood and foliage; the buds were taken about a fortnight ago and are now swelling well with good stems. Louis Bøhmer has good strong growth with buds just taken. Miss M. A. Manda, the yellow Mrs. Alpheus Hardy, is of good strong growth with very well shaped buds, giving excellent promise. W. H. Ballantine, bronze, is not a strong grower but rather free in forming buds, and Messrs. Drover think they will not be able to keep it back for the November shows. In addition to these I noted R. C. Kingston, Mrs. E. D. Adams, Miss A. Hartzhorn, Beauty of Castlewood, Vice-president Audiguier, Beauty of Kinsessing, Mrs. F. Clinton, Gloire de Rocher, and a very promising lot of seedlings.

On the whole Messrs. Drover may be congratulated upon the possession of a very excellent collection, which bids fair to enable them to bring their final season of exhibiting to a brilliant and successful termination.—J. MACK.

GROWING GRAPES IN NINETY DAYS.

A LARGE meeting of the Sunderland Horticultural Improvement Association was held on Thursday evening, September 8th, in the Café, Fawcett Street, Sunderland, when a paper was read by Mr. E. Gilchrist, Claxheugh Grove, Sunderland, on "How to Grow Grapes in Ninety Days." It may, perhaps, be as well to say that a statement made by Mr. Gilchrist some time ago caused some excitement amongst the gardening fraternity in Sunderland and its vicinity, so that the announcement of a paper by him on the subject brought a most crowded meeting.

Breathless silence prevailed during the time Mr. Gilchrist read his paper, of which the following is a brief synopsis:—

A Hamburg house was started on the 6th of February, 1892. The temperature for the 6th, 7th, and 9th of February was 85° by day and 75° at night. From the 9th to the 29th of February it was 95° by day and 85° by night. Throughout the whole of March it was 95° to 100° by day and 85° at night. In April it was 5° less each day till 70° was reached. Till the fruit was ripened these Vines were syringed with a weak solution of nitrate of soda at a temperature of 90°, and the Vines were watered as well. Mr. Gilchrist declined to state the proportions till he has had more experience in the use of it.

We have stated the temperature. On the 17th of February the wonderful bud burst. The Vines flowered on the 19th of March, and on the 28th of March the bunch was thinned, the berries being about the size of No. 4 shot. The bunch was ripe and cut on the 4th of May. The bunch was 15 inches from the evaporating pans, which were filled with ammonia from the commencement till the first bunch was cut. The remaining bunches were from five to ten days later, the house generally ripening in 120 days.

Mr. Gilchrist considers two strong points in favour of the system he has adopted. Firstly, in disbudding the Vines he leaves the basal bud and the terminal bud in each shoot, which he considers will make early Vines quite fourteen days earlier. The second is watering and syringing with nitrate of soda; but he does not recommend the general adoption of his practice, as the chlorophyll in the Vine leaf was not so apparent as he would have liked in June last, and in future he will try the system on pot Vines.

A most interesting discussion followed, when several questions were put to Mr. Gilchrist as to the previous statements he had made to the Society. In reply he said his son stated the house was started instead of closed on the 1st of January this year.

Mr. W. T. Bolam was in the chair. The late Secretary and Treasurer, Mr. J. L. Richardson and Mr. Falconbridge, have resigned their respective positions, and it was resolved that some recognition be made of their valuable services to the Society. Mr. Falconbridge has for many years been foreman at Ashburnham, Sunderland.—BERNARD COWAN.

JUDGING HERBACEOUS FLOWERS.

It will, I fear, be difficult to arrive at a common understanding upon this subject. I suppose most of those who take an interest in hardy flowers have been time after time astonished at awards of prizes to stands of herbaceous flowers which seemed hardly to merit the distinctions given. Mr. Garnett's letter is, therefore, none too soon, and I for one should like to have the views of those who are called upon to judge at shows. Looking at the subject from the point of view of one who is anxious to see the cultivation of herbaceous plants largely extended, I am somewhat doubtful of the wisdom of what I may call the "large spike" system, which would lead to some flowers being cultivated in a manner that lends no beauty to a garden. At the same time there are many plants which should be exhibited in single spikes, or at least in such a way that the individual character of each spike should be seen. There are, again, some flowers which are of little decorative value unless exhibited in bunches. This may be seen in many of the Composites, or in such flowers as *Scabiosa caucasica*, a bunch of which has a telling effect in a stand of cut flowers.

Where there are prizes provided for Phloxes I should be inclined to debar exhibitors from showing these with the herbaceous flowers. Delphiniums occupy a different position, as prizes are seldom offered for these; but I should be disposed to agree with what I take to be Mr. Garnett's opinion, that varieties of these should not be exhibited in the same stand, as tending to weaken the value of the exhibit. With Lilies and Campanulas the case is entirely altered. There are certainly so many different forms that several varieties may be included without weakening the stand. I should say, however, that it is highly desirable to try the experiment of prizes for cut spikes of Lilies grown out of doors, and of excluding these from the herbaceous classes. I know of cases in which Lilies have gained more points than they were entitled to count.

Then, again, the discussion of this question opens up another. What is an herbaceous plant? Some time ago (last autumn I think) a stand was disqualified on account of a *Colchicum* being included. The *Journal*, rightly as I think, took exception to the decision, which could only have the effect of limiting the choice of exhibitors. Generally speaking I think the extract given by Mr. Garnett from the schedule of his Show is a good instruction, but I should fear that in practice it might lead to a hesitation to include new plants, lest they should not recommend themselves to

the judges. This, however, Mr. Garnett, from past experience, should be able to tell us. I hope, however, that the discussion may lead to some more intelligible system than the present one.—S. ARNOTT.

I FEAR that under the conditions suggested by "Devon," page 211, one variety of any flower only being admissible, small growers would require to increase their stock of herbaceous plants if they wished to enter the competitive classes. Surely there is a wide distinction between *Lilium auratum* and *Lilium candidum* or *L. Harrisii*. I have had some experience of the peculiar fancies of judges when adjudicating in these classes. I have had to be content with second place when *Hydrangea hortensis* was included in the first prize stand, and on another occasion a similar stand contained *Spiraea callosa*, a shrub which is easily enough grown 6 feet high in a couple of seasons, and in a very few years will make as much wood as is required in a good-sized faggot. Surely a plant which has this capability hardly comes under the true definition of an herbaceous plant. Many more examples of a like kind could be quoted, all tending to prove that the judging of herbaceous plants is not at all times as it should be, even when the conditions are exact. In spite of this, however, committees are responsible for the correct wording of the schedules they issue.—E. M.

A QUAIN T GARDEN.

CLOSE to the waves of the beautiful Firth of Forth there is a garden more quaint than any I have seen elsewhere. I was sauntering along the sandy beach which borders the Firth near West Wemyss when I noticed what seemed to be a wild garden straggling up the cliff bank. A door opened in the wall, and the gardener came out and invited me in, saying that I should find Shakespearian borders and the plants mentioned by old Parkinson, and that botanists from Edinburgh often come to see the different things collected there. So nothing loth I went in, having plenty of time at my command. The first thing which struck me was a curious sundial. It stood on a grassy hillside, a tall iron index some 6 feet high hung round with creepers, such as common Ivy, *Canariensis*, and *Nasturtiums* growing carelessly about it. In a huge circle the hours were represented in immense figures done in variegated Box, and on the south the name "*Lilian Wemyss, 1890.*" In another circle round the dial, and done with Box in the same way, "*The Lord will make His face shine upon thee and be gracious unto thee.*" Not far from these circles stood an old tree decorated with heart-shaped pieces of wood, painted white with various legends taken from *Ecclesiastes*, *Coleridge*, *Emerson*, &c., such as

"One God, no more; but friends good store."

And on one,

"These beds are round and without ends,
So is my love unto my friends."

Which words refer to two immense circles round the tree tied at the end by a true lover's knot done in Ivy. In the borders which form these circles, and which are about 2 feet wide, are plants of all kinds, only named on tall labels with the name of the giver also underneath. I noticed that *Lily of the Valley* was presented by the Portuguese Minister. *Andromeda floribunda* was given by Mr. Menzies, and was doing well. *Lilium Harrisii*, given by Col. Vivian, was represented only by its name, which is not surprising. Miss Balfour had given "*Anemone hepatica cœrulea*" (*sic*), which to my surprise was in flower in August, but certainly everything was wonderfully late in Scotland this year. Other plants had the names of their donors—Earl of Dunraven, Countess of Clarendon, Mrs. Oswald, &c.

There is not a level piece of ground in the whole garden except a narrow strip by the wall on the seaside. This is occupied with a fine collection of *Hellebores*, which look exceedingly strong and healthy, although they have only been planted for a year or two. On the opposite bank to the sundial are two long borders, one the temperance border, in which all the flowers are white, the other the love border, in which all the flowers are red. Further on are the Shakespeare and Parkinson borders, which are exceedingly quaint and full of extracts from the great dramatist and the herbalist, alluding to the plants growing round the wooden mark on which the quotation is clearly printed. At a corner of the Parkinson border are these words: "*The manner and ordering of many sortes of Herbes and Rootes as used in this Kingdome.*" Then you come to a curious mixture of many things all duly named, Potatoes, Rhubarb, Fennel, Succory, Alisanders, Marigold, Comfrey, and Rue Herbegrace, whatever that may be. Then another quotation: "*Of sweet Herbes as fitter for the pot and kitchen than for the hand or bosome, and such herbes as are of*

most necessarie uses for the country gentle women's houses." Again another: "*The ordering of divers sortes of Herbes for the pot, for meats, and for the Table.*" And again: "*Of divers Physical Herbes fit to be p'anted in gardens to serve for the especiale uses of a familie.*"

Next we come to the Shakespeare borders, which are sprinkled with a great number of quotations in the same way as before, the well-known words, "*I know a bank whereon the wild Thyme grows,*" stand in the midst of a good clump of Thyme. The bits of wood on which these quotations are painted are frequently cut out in the shape of a butterfly. "*Here's flowers for you,*" ("*Winter's Tale*") stands at the head. In these borders I found a Date Palm, which apparently had stood the winter, by it the words, "*They call for dates and raisins in the pastry; the favourite vegetable of our Welsh neighbours with the words, 'His eyes were green as Leeks;' Radishes, 'For all the world like a forked Radish;' and Rushes, 'Lean not on a Rush.'*"

On a high bank behind the garden, and forming a very pretty background, is a plot of Irises, labelled "*Jardin délices (des lys)*" and quotations from Longfellow:—

"Thou art the Iris fair among the fairest,
Who arm'd with golden rod
And winged with celestial azure, bearest
The message of some god."

and on another label among the flagleaves of the Iris,

"Oh, flower de luce, bloom on, and let the south air
Linger to kiss thy feet;
Oh, flower of delight, bloom on, and make for ever
The world more fair and sweet."

On the sea wall, under a cover which was secured by a padlock, was a very beautiful sundial; the gardener showed it to us with a great deal of mystery. Scattered about on "the brae," as the gardener called it, were some fine Foxgloves which looked well, also some *Lilium pardalinum* more than 6 feet high. In the centre of the garden was a "Rose tent," a large circular bed with a sort of huge skeleton umbrella over it. Roses of various kinds are being trained to the wires which are fastened in the centre to the top of a tall pole. This will require some years to pass away before it can attain its full beauty.

We went on further to the fine gardens at Wemyss Castle, where Mr. Clarke, the head gardener, showed us over his exceedingly beautiful and well-kept garden with true Scotch courtesy. Mr. Clarke has also, of course, the superintendence of the quaint garden by the sea. But at the Castle the beds and ribbon borders are a perfect blaze of colour, Pansies especially growing with great vigour, and bearing masses of bloom. Mr. Clarke informed me that sea salt often covers the walks with a white crust after a storm, and that he had found it utterly impossible to cultivate Vegetable Marrows in any corner of the garden. I expressed some surprise that the beautiful creeper so common in Scotland (*Tropæolum speciosum*) was nowhere to be found, and we were told that it would not grow on the shores of the Firth of Forth. I had, however, seen it not far from the Forth, but a little more inland, where it was doing well. I forgot to mention that the quaint garden by the sea was made much more interesting by the ruins of an old abbey, which stood at one end of it. But little of the abbey is left, still the remains of an old tower, with doves flying about, certainly add not a little to the picturesque appearance of this strange garden.—J. L. S.

PLANT CULTURE BY CROSS-FERTILISATION AND HIGH SELECTION.

WE have need at times to visit the experimental grounds of our leading seedsmen to discover what new varieties of vegetables and flowers they are bringing to perfection for commerce. The general public when inspecting flower shows and horticultural exhibitions are naturally amazed at the large number of these new varieties, but they know little or nothing of the amount of artistic skill underlying their production. Just as a sculptor has before his mind's eye an ideal, or the potter in moulding his clay seeks after something more perfect than he has ever wrought, so does the horticulturist in love with Nature and striving to fathom her secrets endeavour by cross-fertilisation and high selection combined to aim after more beautiful flowers and grander types of every kind of plant life than has ever before been seen. Sometimes he has to labour long and suffer grievous failures ere he succeeds, cross-fertilisation being too frequently an *ignis fatuus* to follow. Still, one genuine success compensates for many years of anxious labour, and we need scarcely say that many valuable new varieties have been raised.

This connection between the plastic arts and the creation of new forms of vegetables and flowers was enforced on our attention last week in passing through the Staffordshire pottery district, where exquisite works of art in porcelain are always on view, and then proceeding immediately to the not far distant Kinver gardens and farms of Messrs. Edward Webb & Sons, the world-renowned seedsmen of Wordsley. These

are very extensive, for when we visited them last they were said to be nearly 2000 acres; since then field has been added to field and farm to farm, and only last week a fresh purchase was made which will add another farm to the estate. Messrs. Webb own as well as occupy the greater part of this land, and it is the extension of trade and the colossal scope of their undertakings that render the acquisition of more land desirable. The Wordsley warehouses have been almost entirely built during the past half dozen years, the two largest being each 182 feet long and 62 feet wide with six floors, all 13 feet high. On the site where they stand every bit of ground has been covered with warehouses and offices, except a small bright grass plot, which has been the outlook from the private luncheon-room. But a fresh erection is about to be raised on this, as a considerable increase of clerks had to be made this summer for whom there was no room without hiring offices for them outside.

As is well known, all our leading seedsmen get the bulk of their seeds grown for them in other parts of the kingdom and on the Continent best adapted to the respective varieties, only requiring experimental grounds for testing purposes and for the production of new varieties at home. Messrs. Webb & Sons do the same, over 18,000 acres altogether being required to produce seeds and seed corn for the gigantic Wordsley establishment. The reason that the Kinver farms have to be so large is chiefly owing to the realm of Ceres having been added to the domain in which cross-fertilisation and high selection hold sway. Selecting the best from the best continually from the heads in crops of Wheat, Barley, Oats, &c., requires a broad scope of acreage which only large landowners and farmers can work with successfully. That they have done so for the past quarter of a century, so as to earn the gratitude of the farming community for better varieties of all the cereals than were commonly grown before, is attested to continually by numerous facts, one of which will suffice for our present purpose. The Brewers' Exhibition has existed five years, and at each annual show a challenge cup has been offered, open for competition to the entire world, for the best malting sample of Barley. This has been won each time by the same variety, Kinver Chevalier, one of those which Messrs. Webb have brought to its present high degree of perfection by continuous high selection.

In our visit to the trial grounds we had to pass through the flower gardens first, where we were glad to find many plants in full bloom of considerable merit. New Challenge Antirrhinum was brilliant in colour, and made a grand show. Among several members of the Dianthus family Champion also presented some showy perfect flowers. Chrysanthemums were well represented by White Pearl and Golden Cloud, which stood in beautiful contrast to each other. The New Golden King Calliopsis had a bright golden effective appearance, New Eclipse Gaillardia appearing truly magnificent in mixed beds, and the Kinver expert deems it one of the choicest of the floral beauties he has originated. Hollyhocks were, of course, in grand show, placed in banks on either side of a gravel walk, and there was a New Prize variety brought out in the past season for the first time, which seemed very effective. Of Zinnias and Stocks there were several varieties which asserted their charms very powerfully, the single Dahlias being also noteworthy. In Asters there are marked successes, especially in the quilled and miniature specialties, and among the Marigolds the newest called Golden Striped fully justified high appreciation. Some exquisite floral gems were noticeable in dwarf Pansies, and the Golden-laced Polyanthus is a genuine success, but it was, of course, too late in the season to see their charms, or those of the Poppies, which we were told had been very brilliant.

All the most important kitchen garden vegetables which market gardeners and farmers also grow largely, such as Potatoes, Peas, Cabbages, and white-fleshed Turnips, have been so thoroughly and continually subjected to cross-fertilisation and high selection at Kinver, that a great many valuable varieties have been evolved. The rigorous searching ordeal which has to be passed through gives the public every assurance that there is only a "survival of the fittest" among the many hundreds of new kinds created by cross-fertilisation, so that in regard to Potatoes we may be perfectly sure that the three leading varieties for which Messrs. Webb are at the present day most distinguished, Stourbridge Glory, Wordsley Pride, and Renown, are all of intrinsic value, and likely to hold their own in future. Having stood the test of several seasons they are tolerably well known as grandly shaped varieties of high quality. We pass on then to mention that there are over 300 new seedling Potatoes on trial at the present time, some of which are of high promise, and will probably soon be brought into commerce. Past experience has, however, proved that it is not well to rush a successful variety too soon into the market, however certain it may be that it will be well appreciated. Several of Messrs. Webb's were introduced too soon, for in their second season the demand exceeded the supply. There is, however, one at least of the new seedlings likely to be brought out next year, which, according to the testimony of the expert, will be almost sure to prove of the highest value, not only on account of the tubers being well shaped and very fine, but because they come to maturity a fortnight earlier than any Ashleaf. It somewhat resembles Beauty of Hebron, which is one of its parents.

There are also several very interesting varieties of new Peas which have been a long time under trial, and will probably turn out genuine successes. Considerably over a hundred not yet in commerce are undergoing experimental tests on the grounds, some of which will survive and others fail. The cross is always from valuable parents, but most singular sports are sure to come, the same growth producing half a dozen different varieties perhaps, and every Pea in a single pod is

sometimes different. This shows how necessary rigorous exclusion of all but the most perfect must be. This appears to be carried out most effectively at Kinver, the slightest failing being sure to be visited with discarding, so that in very truth only the "survival of the fittest" is secured. One new seedling Pea which has come safely through every test will be brought out next season. This is a cross between Prince of Wales and Culverwell's Giant Marrow, and it is possessed of sterling features of value calculated to exalt it highly in general estimation. Of medium height, it seems so covered with pods that no leaves could be seen, and the pods when examined were found to be well filled with fine Peas of good quality. There are more than a dozen other new seedling Peas that have succeeded so well that it is almost certain they will ultimately be brought into commerce, but the one above mentioned is just now first favourite at Kinver, and after Talisman, Promotion, Royal Standard, Chancellor, and Wordsley Wonder, all of which are of high reputation and were raised at Kinver, we may, no doubt, expect great things for the future. We have stated that one of the parents of the new Kinver seedling was Prince of Wales, but there are different varieties bearing that name. Mr. H. E. Thornley of the Royal Prize Farm, Leamington, who habitually grows Peas largely to pick for direct sale, speaks in high terms of a Prince of Wales crop grown from Kinver seed, whereas another crop of the same name, but for which the seed was obtained elsewhere, turned out anything but satisfactory.

Messrs. Webb have a new Carrot called Market Favourite, having a very handsome solid appearance recommended for early use, but for general use they recommend their Defiance Intermediate. Emperor Cabbage enjoys such a high reputation amongst farmers and market gardeners alike that it seems almost too much to hope for anything new likely to surpass it, however assiduously the arts of high selection may be employed. It comes to perfection so very early that even in the largest and best kitchen gardens it has place; but the Emperor deserves its name owing to great size and heavy weight, and when cut open the hearts are found to be of high quality. The Kinver Globe Savoy is also very globular, with solidity and excellent quality likewise. In Broccoli we found that the specialties are still May Queen and Perfection, both of which have long been favourites. Gardeners also know something of the Matchless Brussels Sprouts and Perpetual Dwarf Green-curved Kale which have been raised at Kinver. Early Mammoth Cauliflower is often a prizewinner at shows. In Turnips, the variety for table use which has taken most prizes is, perhaps, the Climax, early in growth yet adapted for general cultivation, and good for keeping purposes.

The varieties of Lettuces are innumerable, and some of the Kinver ones almost as big as Cabbages; but if large, Summerhill is also compact and handsome. The American Gathering appears, however, to be of equal appreciation among the Cabbage kinds, while the Cos Lettuces are headed by Monstrous, which, although large and handsome, gives crisp leaves of fine flavour. That Melons are brought to high perfection is proved by two of the best being named Pride of Stourbridge and Beauty of Wordsley; but President and Queen Victoria are also exquisitely shaped, fine, handsome, and good. Snowball Onion has often won prizes at shows, and we need scarcely mention its silvery white skin and good flesh. Among Leeks Colossal has often taken the palm. A great many new varieties of Cucumbers have been brought out at Kinver, and, indeed, the same may be said of Radishes. Celery has been by no means neglected, and Pearl White has come largely into use, as well as the Mammoth Red, which is very hardy, and has gained several first prizes. There is a very large family of Runner, Dwarf, and Butter Beans at Kinver; and the Giant White Runner, the Victoria Dwarf, and Webbs' Golden King Butter Bean are all prime favourites. In Broad Beans Kinver Mammoth Long-pod shows that the art of high selection has been well applied even here.

Ere passing out of the trial grounds we should mention that the grass plots which divide flowers from vegetables form in themselves a most interesting study, each being kept separate to its respective kind. The Fescues are all represented, as well as the Poas, while other sections are devoted to Cocksfoot, Timothy, Meadow Fox-tail, and the Rye Grasses. For lawns of all kinds, whether for tennis, archery, croquet, or cricket, Messrs. Webb supply special mixtures with ample directions. They have for some years also published an illustrated essay on "The Formation of Permanent Pastures," the latest edition of which is full of interesting information.

For agricultural, if not for general purposes, the whole of the extensive farms occupied by Messrs. Webb may be deemed trial grounds in their entirety. Labourers are sent into all the corn crops every year to select the finest heads from all the pedigree or highly selected crops, some being of Webbs' Prolific Black and White Tartarian Oats, or of Webbs' Challenge White Oat and others of the Kinver Chevalier Barley above referred to, or of Golden Grain, Beardless, Goldthorpe and Golden Melon Barleys, or of Webb's Challenge Hybrid King, Windsor Forest, White Queen, and at least a dozen other varieties of Wheat. Of Mangel Wurzel, Swedes, Yellow-fleshed and White-fleshed Turnips the varieties are still more numerous, and a considerable proportion of them have been prizewinners at shows. These are all tried one year after another with the best approved specialties from other seed firms, Messrs. Webb being always anxious to discover whether they can be beaten or not. Nor do their private trials end here. They have now become one of the largest artificial manure vendors in the kingdom, and being desirous to excel as much in this department as they believe they have done in seeds, they try habitually the manures of other leading firms against their own over a wide acreage of Mangel Wurzel, Swedes, Turnips and Potatoes.—D. S. N.

EVENTS OF THE WEEK.—There is a break in the long run of shows, and the ensuing week will be a very quiet one, affording opportunities to attend the various auction sales now announced. A meeting of the Brighton and Hove Chrysanthemum Society will be held to-day (Thursday, September 15th), and the usual Committee meetings of the Royal Horticultural Society will take place on Tuesday, September 20th, at the Drill Hall. There will be bulb sales at Mr. J. C. Stevens' rooms, King Street, Covent Garden, on Thursday, Monday, and Wednesday. On Friday, September 16th, there will be a sale of Orchids at Messrs. Protheroe & Morris's rooms, 67 and 68, Cheapside; sales of bulbs will be conducted every day; and there will be sales of plants on September 19th and 22nd.

— THE WEATHER IN LONDON.—Showery and cold weather prevailed when our last issue was published, but towards the end of the week it became brighter and much warmer. Still higher temperatures were registered on the 11th, though the early part of the day was cloudy, and the 12th was close and hot. The barometer fell considerably towards night, but the 13th remained bright, warm, and fine. At the time of going to press the barometer shows a considerable rise, the wind is westerly and light, and the weather fine, though slightly cooler. On the whole it has been a favourable week for harvesting and fruit gathering, while there is a promise of similar conditions prevailing for some little time. The reports as to the state of the Potato crop are satisfactory on the whole, and the weather has been against the spread of the disease.

— VARIATION OF HARDY PLANTS.—The variation of hardy plants under cultivation has proved a source of interested observation to many growers, and it has been chosen by the Rev. C. Wolley Dod for the subject of a lecture at the next meeting of the Royal Horticultural Society. As an experienced cultivator and close observer he may be trusted to treat it in a manner that will earn the thanks of all flower lovers.

— THE INTERNATIONAL HORTICULTURAL EXHIBITION.—The last weeks are announced of this popular Exhibition, which has done so much to enliven what otherwise promised to be the dull season on record. Buffalo Bill and his Wild West will take their leave on October 12th, sailing for their native shores three days later by the s.s. "Mohawk" of the Atlantic Transportation Company, a vessel of 8000 tons, which has been specially chartered for the occasion. As this will be the very last that Europe is likely to see of Colonel Cody and his great show as an organisation it behoves those who want to pay a farewell visit to the Wild West to avail themselves of the opportunity that is still offered of their doing so. The Exhibition altogether, with the combined attractions of its grand floral display, its splendid music, and the spirited performances in the Wild West arena, forms a pleasure resort that London will be sorry to lose, and which will be gratefully remembered for many a year to come.

— POTATOES AT CHISWICK.—The Potatoes on trial in the Royal Horticultural Society's Gardens were examined on Tuesday last. Out of upwards of eighty varieties twenty were chosen, in consequence of their good and disease-free crops, to be further tested by cooking. We can only say at present that out of these three marks of merit were awarded to Laxton's Short Top, the earliest variety and productive; Boston 22 (Johnson) a fine white round; The Canon (Dean), also sent by Messrs. Carter & Co., an excellent white kidney; Reading Giant (Fidler), a large productive white kidney; Mary Anderson, similar to it; and King of the Earlies, a variety of the Ashleaf type. The table quality of some other varieties was not sufficiently developed through the tubers not being quite ripe, and many tubers of several varieties were tainted with the disease. The members of the Committee present were Philip Crowley, Esq., Chairman; Dr. Hogg, and Messrs. H. Balderson, J. Hudson, G. Taber, G. Reynolds, J. Smith, W. Warren, J. H. Laing, G. Reynolds, A. Dean, G. Clyffe, G. W. Cummins, G. Sage, and J. Wright.

— FIRE PROTECTION AND WATER SUPPLY.—A pamphlet on the subject of the fire protection of towns and buildings, with remarks on water supply, has just been published. The author is Mr. J. Compton Merryweather, M.I.M.E., who is well qualified to deal with the subject treated.

— FICUS ELASTICA AND ASPARAGUS FRUITING.—There is here (Tynningham) an old plant of *Ficus elastica* kept for propagating purposes, which, in most seasons, brings a crop of fruit to maturity. *Asparagus plumosus* also fruits, and *A. tenuissimus* carries large crops of berries.—B.

— CACTUS DAHLIA MATCHLESS.—This new variety obtained a first-class certificate at the Reading Show recently. It was exhibited by Messrs. Perkins & Son of Coventry. The variety has good red flowers of the rich dark hue of Empress of India, but is of true Cactus form, and should later be found in the best collections.

— DEVERILL'S PEDIGREE ONIONS.—The annual display of Deverill's Pedigree Onions, grown in different parts of the United Kingdom, will be on view at the Royal Oxfordshire Seed Establishment, Cornhill, Banbury, on Thursday and Friday, September 15th and 16th, when valuable prizes will be awarded. They will be worth inspecting by any grower of this useful vegetable who may have an opportunity of calling. The entries number ninety, the specimens 1264. The heaviest dozen bulbs are Ailsa Craig, which weigh 26 lbs.

— MELON SUTTONS' A1.—If I were to say that this Melon is destined to occupy as prominent a position amongst the scarlet-fleshed varieties as Hero of Loeking does amongst the green-fleshed, I should not be very wide of the mark. Having tried it last year, and again this year, I have proved it to be equally as good for frame as for house cultivation. It is a good grower, a free setter, and beautifully netted. The fruit is of great depth, and the flavour is, as the name implies, A1. It is a real gain, and therefore worth acknowledging.—R. P. R.

— SHOW AT GHENT IN 1893.—We have received a schedule of the great Show that is to be held by the Royal Agricultural and Botanical Society of Ghent from the 16th to the 23rd of April, 1893, and of which previous announcements have been made in the columns of the *Journal*. As 660 classes are provided it will be clear that the Show will be of a comprehensive character, admitting a great variety of exhibits. Readers may be reminded that Comte O. de Kerchove de Denterghem is the President of the Administrative Council, and M. A. L. Rosseel the Secretary.

— MESSRS. PROTHEROE & MORRIS.—These well-known auctioneers have acquired so large a connection by enterprise and sound business methods that it is no surprise to find that they have been compelled to considerably extend their City premises. A large and well-lighted room has been secured immediately at the rear of their present large sale-room at 67 and 68, Cheapside, and can be entered from the latter or from 3, 4, and 5, Queen Street. It will be illuminated by means of the electric light, and will add so materially to the facilities at the firm's command that a considerable extension to their already large scale of operations can be effected.

— CYCLAMEN NEAPOLITANUM.—At this time of the year few prettier effects are produced than a good flowering clump of this hardy Cyclamen, especially when planted in a nook on a rockery. The flowers stand about 6 inches above the soil, and are produced plentifully from the large, flat tubers. The leaves are cordate, about 2 inches long and the same broad; they commence to unfold when the plants are flowering. The flowers are white or pink and red with a purple base, the corolla segments about three-quarters of an inch long. Though introduced from South and Central Europe *C. neapolitanum* is quite hardy, and has become naturalised in many parts of Britain.—C. K.

— THE HERB MACE.—I have been a constant reader and subscriber to your valuable *Journal* from the year 1852, and the whole of that time this herb has been grown. It is commonly used by cooks with other herbs for making force meat for fowls, &c. I have taken it into the kitchen when a boy, and have sent it in ever since. Some months back I was asked its botanical name, and could not give it. I have been taught that *Achillea serrata* has a yellow flower; the example I sent to you has a white flower.—JOHN COPE. [*Achillea serrata* has white flowers. Our correspondent omits his address. We shall be glad to have a few rooted offsets of the herb, which we know is grown and used in the North of England.]

— **DEATH OF M. JOLIBOIS.**—The death is announced of M. Jolibois, head gardener at the Luxembourg, at the too early age of forty-nine. The French horticulturist was an able gardener and his loss will be much felt. He held various distinctions, such as Officier d'Académie, Chevalier du Mérite Agricole, and Chevalier de la Légion d'Honneur. He was also a member of the Council of the French Horticultural Society and a Professor of Arboriculture.

— **CLEMATIS DAVIDIANA.**—A notable feature of the miscellaneous collection of hardy flowers exhibited by Messrs. Pitcher & Manda at the last Earl's Court Exhibition was Clematis Davidiana, a hardy herbaceous species growing about 2 feet high. The flowers are produced in whorls, of which there are two or three on a stem, the lowest close to the ground, so that the plant has the appearance of being a mass of bloom. The individual flowers closely resemble Hyacinth bells, and are of a clear lavender colour. It appears to be well worth adding to the mixed border.

— **A HANDBOOK OF IRIDÆ.**—The "Kew Bulletin" for September contains special articles on Caraguatá Fibre, Lagos Palm Oil (with illustrations), and commercial Vanillas, also a considerable amount of miscellaneous information. We note an announcement that Mr. J. G. Baker, F.R.S., has in the press a handbook of Iridæ, uniform with those which he has already published on the neighbouring orders Amaryllidæ and Bromeliacæ. The order contains about sixty genera and 800 species, nearly half of the latter being concentrated at the Cape. The large garden genera of the order are Crocus, Iris, and Gladiolus. More than one-half the book is already printed, and it will be completed in a few weeks.

— **FRANCOA RAMOSA.**—An indispensable plant for greenhouse or conservatory decoration at this season of the year is Francoa ramosa. When associated with other plants, more especially in grouping, its long spikes of white flowers suffused with pink have a telling effect, and add a charm to a group which cannot be denied. Small plants in 5 or 6-inch pots are most useful for house decoration, especially if they have been well grown and the foliage kept perfect. It is also a most accommodating window plant, scarcely requiring any heat, and always sure in flowering. Plenty of seed may be secured, which if sown as soon as ripe, and placed in a warm temperature, will yield abundance of useful little plants for another season. It may also be increased from cuttings or by dividing the plants. As to soil, any good loamy soil with a little sharp sand will answer all requirements.—R. P. R.

— **APPLE IRISH PEACH.**—I make no apology for bringing before the notice of your readers such an excellent early Apple as the Irish Peach. It is not by any means a new variety, but there is no reason why it should not have attention called to it on that account, for it generally takes a long time to establish the merits of a good fruit; it took half a century to establish the fame of Cox's Orange Pippin. The Irish Peach is, for juiciness and flavour, as far ahead of all other early English grown dessert Apples I have tasted as Cox's Orange Pippin is of the later kinds, and it should take first prize for quality against all inferior sorts, however pretty they may look. I have had a capital crop this season of fine, clean, healthy, and well ripened fruit, and with me Irish Peach is a good grower and an abundant bearer; care is, however, needed in pruning, as its tendency is to bear on the points of the shoots.—F. BOYES, *Beverley*.

— **STRIKE AGAINST MARKET TOLLS.**—Some excitement was caused at the Brighton Market on Saturday morning by the seizure of several bushels of Potatoes and a bushel of Apples from a market gardener named Cuddington of Shoreham in consequence of his refusal to pay the market tolls. At Brighton there is no covered vegetable market, and the gardeners who come into the town are compelled to stand out in the streets in the vicinity of the flower market, and to sell their produce exposed to all kinds of weather. For some time past a feeling has been growing that the Corporation have no right to charge tolls without supplying adequate market accommodation, and on Thursday morning many of them refused to pay the tolls when demanded. It was subsequently arranged on both sides that a seizure should be made from Mr. Cuddington, and that the goods should be sold by auction to cover the amount of the toll he refused to pay and the costs. This it was decided should be done as the basis of a test case. The arrangement was duly carried out, and the sale took place amidst some good-tempered excitement. Mr. Cuddington urged the crowd not to bid for the goods, declaring that their seizure amounted to nothing less than robbery, and that the purchasers would be buying stolen goods. Despite

this protest the lots were disposed of, more than one being purchased by Mr. C. Sutton, a member of the Corporation. The sale realised 17s., and after deducting the toll, 1s. 6d., and the costs, there remained an overplus of 4s. This was offered to Mr. Cuddington, but was refused. The gardeners have not yet decided what course they will take to raise the question of the legality of the tolls in the law courts. Several courses are, it is said, open to them.

— **AUGUST RAINFALL IN SUSSEX.**—The total rainfall at Cuckfield, Sussex, for the past month was 2.61 inches, being 0.31 inch above the average. The heaviest fall was 0.70 inch, on the 18th. Rain fell on sixteen days. The highest temperature was 79°, on the 17th; the lowest 46°, on the 11th. Mean maximum, 72°; mean minimum, 53°; mean temperature, 62.1°. Partial shade readings the average. The last ten days have been very showery, with occasional high winds.—R. I.

— **SEAKALE AT OAKLEY HALL.**—"South Hants" has been in a little too much haste to make merry at my expense. In the remarks which he quotes in relation to the above I was not assuming surprise that Seakale came good from cuttings. Of course I should exhibit no such ignorance of so very simple a subject. If the context is read it will be seen that I had remarked on the peculiarly ungenerous nature of the soil, which would not grow Raspberries or Black Currants, and added, "curiously enough Seakale from cuttings is first-class." That was a natural corollary. I was surprised to find a root of this nature, which always seems to do best in deep rich soils, to be in such first-class form as Mr. Weaver had it in his garden at Oakley Hall.—A. D.

— **LOBELIA MILLERI.**—This Lobelia is occasionally seen labelled as *L. speciosa*, but its strictly botanical name is *L. syphilitica hybrida*; notwithstanding this plurality of names the one heading this note is no doubt the one under which it is most generally known. *L. Milleri* is supposed to be a hybrid between *L. syphilitica* and either *L. fulgens* or *cardinalis*. The leaves are acuminate, sessile, serrated, and light green. The stems grow 2 to 3 feet high, carrying spikes of large flowers very much like those of *cardinalis* in shape, but of a beautiful rich purple colour; the spikes elongate and continue to flower until frost comes. To produce fine spikes the plants should be placed in a somewhat sheltered position and in good soil; a deep corner in a rockery will suit them admirably. It is one of the very finest of the late flowering hardy herbaceous plants.—C. K.

— **APPLES AT CHISWICK.**—The Apple trees in the gardens of the Royal Horticultural Society at Chiswick were a pleasant and instructive sight on the occasion of a recent visit. Many varieties were loaded with fruit. New Hawthornden was weighed down with it, and the branches have had to be supported with stout props. Lane's Prince Albert was carrying an excellent crop, and Dutch Mignonne was roped with fruit. Others that were heavily laden were Calville St. Sauveur, Golden Noble, Stirling Castle, Gloria Mundi, Barchard's Seedling, Cellini, Cox's Pomona, and Baumann's Red Winter Reinette. Frogmore Prolific, as represented by small bushes on the Paradise stock, was bearing a heavy crop of its large handsome fruits, and the little trees were a truly striking sight. That it would prove a profitable Apple when grown under similar conditions to those at Chiswick is unquestioned, but I know of an instance where it has proved a complete failure in Kent.—P.

— **EARLIER OPENING OF KEW GARDENS.**—Mr. Shaw-Lefevre has received the following communication, bearing upon the re-opening of Kew Gardens, from Mr. Francis Geo. Heath:—"A consideration of your well-known desire to give facilities for the public enjoyment of open spaces, of your admirable service to the Commons Preservation Society and kindred institutions, and of your labours for the rescue of Epping Forest and Burnham Beeches from the hands of the spoilers—labours which I have myself had the honour and pleasure of joining in—tempts me to take advantage of your appointment to the Cabinet post of First Commissioner of Her Majesty's Works and Public Buildings by calling your attention to the great desirability of a somewhat earlier opening of the splendid Botanical Gardens which, amongst many other important open spaces, now come under your supreme control. I am fully aware of the important and weighty reasons which can be urged against a too wide relaxation of the present rules as to the opening of Kew Gardens, and I do not desire to ask for any urgent consideration of the matter. But knowing how strong is the feeling on the part of the public on the subject that at least some little compromise should be made in the direction of an earlier opening of these beautiful and well-managed grounds—a feeling not only shared by the people of Kew

and Richmond, but by a much larger outside public—it has occurred to me that you would probably be willing to allow the subject to be discussed with you by a deputation. Possibly some time during the autumn, when it would be quite convenient to yourself, you would kindly permit such an interview as I venture to suggest." Mr. Shaw-Lefevre replied in the following terms:—"One line to thank you for your kind letter. I shall be very glad to see you here later in the autumn on the subject of the opening of Kew Gardens. In November next I shall be continually at work here, and any day will then suit me."

— **BLUE-PODDED BEANS.**—In a particular quarter very much has been made of the exhibition of a blue-podded Bean recently at the Earl's Court Show. Any visitor to Chiswick Gardens may see several varieties of this coloured Bean in fruit, and Mr. Barron will tell them that they are not novelties. The colour naturally detracts appreciably from their edible uses. They have also no appreciable merit. Really they belong to the Butter or Skinless types, the best of which by a long way are the Green Hungarian and the French Mont d'Or (golden) varieties. Those who would like a really pretty ornamental Bean should grow the Red Striped; the pods are sulphur coloured, profusely streaked with red. Were this form, the golden Mont d'Or, and the violet-podded varieties, grown mixed for ornamental purposes, especially to cover bowers or arches, they would be found very pleasing, as all the pods are so distinctively marked or coloured.—A. D.

— **PRESTON AND FULWOOD HORTICULTURAL SOCIETY.**—The last monthly meeting of this Society proved to be a pleasant and instructive one. There were exhibits by Mr. Terry, gardener to H. Calvert Esq.; Mr. Rigby, gardener to J. Smith, Esq.; Mr. H. Winwood, Mr. J. Wilding, Mr. Jas. Ashworth, Mr. W. Morris, Mr. Frisby, gardener to Miss Farington; Mr. W. Troughton, and Mr. S. H. Stott. The latter contributed some splendid Roses, which lent emphasis to the admirable paper on Rose growing which he subsequently read. Mr. Atherton's announcement that the Mayor had consented to become President of the Society in succession to Mr. Hanbury, M.P., was received with great satisfaction. It has been decided that the spring Show shall be held on March 16th and 17th. Approval was expressed of Mr. Payne's suggestion that prizes should be awarded at the end of the season for exhibitors gaining the largest number of points for skill and perfection in culture.

— **NEW VIOLAS.**—Messrs. Dobbie & Co. send us a box of beautiful Violas, comprising Princess Beatrice, Ravenswood, Rosine, Duchess of Fife, Sunrise, Wm. Niel, York and Lancaster, Rothos, Columbine, and Violetta, also four new varieties to be sent out in 1893. Edina is a very handsome flower, rich deep velvety purple with lavender upper petals, somewhat recalling Countess of Kintore, but perfectly distinct. If of good habit and a free bloomer it will take a high place. Prince of Orange is a bright orange yellow, with rayed centre. Peter Barr has a yellow centre, banded nearly half the breadth of the petals with purplish rose, and having paler upper petals. Rob Roy is a round, smooth flower, lower petals bright yellow, upper brownish purplish, margined with clear yellow. Of the older varieties sent we consider Violetta the pick. It is one of the miniature Violas, is of delicate and beautiful appearance, and powerfully scented. There is a great future before this and the others of its class.

— **MANSFIELD HORTICULTURAL SOCIETY.**—The annual meeting of the members of this Society was held at the Mechanics' Institute, Councillor Sanders presiding. Mr. W. Godfrey, the Secretary, presented a financial statement, which was adopted, showing a deficit on the year's working of £16 18s. 7d., and there was a balance in hand at the bank of £12 13s. 6d. Mr. W. F. Webb, J.P., Newstead Abbey, was re-elected President, and the Vice-Presidents were also re-appointed, with the addition to their number of Mr. I. H. Wallis. Messrs. H. Oakes and H. Rawson were re-elected auditors, and all the old members of the Committee were chosen by ballot to serve again next quarter, with the exception of Mr. H. Smith, who retired, and whose place was taken by Mr. W. N. Sarll. Ald. D. J. Patterson was re-appointed Hon. Treasurer, Mr. W. Godfrey Secretary and collector, and Mr. J. Newton Hon. Secretary for the monthly shows. These gentlemen were heartily thanked for their past services. The amended rules presented by the Committee were considered, and, after considerable discussion, adopted. The area covered by the annual Show will now be extended to a radius of ten miles. It was decided to hold the annual supper at the end of the present month. After the business of the meeting was concluded, a Show of Vegetable Marrows, Carnations, and Picotees was held. The Judges were Messrs. H. Rawson, G. B. Andrews, and G. Edwards, their awards being as

follows:—Vegetable Marrows—First, Mr. W. Haynes. Second, Mr. J. Caunt. Third, Mr. S. Buttery. Fourth, Mr. J. Slaney. Carnations or Picotees—First, Mr. H. Leeson. Second, Mr. W. Brindley. Third, Mr. R. Boole. Fourth, Mr. J. Taylor.

— **EUPHARIS AMAZONICA.**—I have sent to your notice a spike of the above, which you will see has nine flowers and buds upon it. I do not recollect ever having seen one with so many flowers before. You will also observe that one of the flowers is a double one—a fusion of two into one. A few years ago I sent you a similar example, but I do not think that there were so many flowers upon the spike. It would appear in this case that some excess of vigour is the cause of the monstrous flower as in the spike, otherwise there is nearly double the usual number of flowers. Possibly this incident may be worth recording.—ROBERT MACKELLAR, *Abney Gardens, Chesham*. [A beautiful head of bloom, and the foliage indicates robust health.]

— **SCOLE FLOWER SHOW.**—The annual Show of vegetables, fruit, and flowers for the parishes of Scolt, Frenze, Thorpe Parva, and Thelveton, took place at Scolt House. The exhibits were shown in two spacious marquees, and the quality of the exhibits was good. In the open classes, the Rev. G. Farrow, Rickingham, and Mr. J. P. Frere, Roydon Hall, were the principal winners. In the cottagers' exhibits the Judges must have had a severe task in making their awards. Mr. Rose, besides taking thirteen prizes, also gained third prize in the open competition for the best basket of vegetables. The lateness of the season proved an advantage, all classes being well represented, while fruit was beyond all that could be expected. Flowers were likewise a special feature, some of the cottage exhibitors putting several noted growers in the shade. Mr. A. Kerridge, of Palgrave, showed a splendid lot of pot plants; while Mr. William Jackson, of Scolt, was awarded an extra prize for three Swedes and three Mangolds, also not for competition. A band was in attendance, and the arrangements were under the supervision of a strong Committee. The duties of Secretary were efficiently carried out by Mr. R. W. Clarke.

— **TELEKIA SPECIOSA.**—This plant under the above and another of its many names (*Bupthalmum*) has been in your last two issues awarded much higher praise than in my opinion it can fairly lay claim to, as it is an exceedingly coarse growing plant, only suited to the wild or weed garden, or to the banks of a pond or piece of ornamental water in a pleasure ground surrounded by tall trees, where a bit of colour is wanted. When once carefully planted it can henceforth take care of itself. It is well figured on plate 3466 of volume lxiii. of the "Botanical Magazine" for 1836; and is also known under the synonyms of *Molpadia suaveolens*, *Inula caucasica*, and *I. macrophylla*. On the pond bank it would form a suitable companion to the handsome foliaged *Gunnera scabra* (which, however, requires a covering of leaves or bracken to protect its crown from severe winter frosts), or to *Saxifraga peltata*, which is only seen in its full beauty when it has its toes in the water, and of which the autumnal tints when lying well to the sun are often quite gorgeous. For a much brighter and broader rayed flower, of much less coarse habit of growth, and eminently suited for the choicest herbaceous border, I would recommend all lovers of handsome hardy flowers who do not already possess it to get *Inula glandulosa*, figured on plate 1907 of volume xlv. of the "Botanical Magazine."—BOSCOBEL.

— **A GOOD FLY AND WASP TRAP.**—At this time of the year, when Peaches, Plums, and Pears on open walls are ripening, the large blue flies and butterflies, particularly red admirals, are exceedingly troublesome. It is surprising what a quantity of fruit the former will spoil in a short time if means are not taken to prevent them. Some persons suspend bottles half full of beer sweetened with sugar among the branches, and in some instances they answer fairly well, but the most efficacious trap that I know of is one made of two ordinary hand-lights of the same size, closely glazed, placed close to the tree most affected. On the top of four half-bricks, one at each corner, place one light, cut a small hole just large enough to admit of a wasp passing through in the glass at the apex of the light. Over this light place another, packing the sides on which it rests with moss, in the case of its not fitting tightly, to prevent the escape of any flies. On the ground underneath the light lay some partly eaten fruit, which will entice the enemy, some being induced to ascend through the hole in the bottom light into that at the top, from which they never appear to be able to find their way. More will quickly follow, and it is surprising what a number of flies, wasps, and butterflies are caught in a few days; in fact they apparently prefer the company of their kin to the fruit on the trees.—E. M.

SOPHRO-CATTLEYA VEITCHI.

AN interesting and brilliant trigeneric hybrid was placed before the Orchid Committee of the Royal Horticultural Society on September 6th by Messrs. James Veitch & Sons, and was awarded a first-class certificate. It is the result of a cross between a variety of *Laelia elegans* (*Laelio-Cattleya*) and *Sophranitis grandiflora*. The plant was only about 4 inches high. The flowers are of a beautiful rosy carmine hue, the lip deeper, inclining to magenta, and the throat tinged with yellow. The woodcut (fig. 34, see page 245) accurately portrays the form of the flower. This hybrid is remarkably attractive and naturally evoked considerable interest.

CATTLEYA OWENIANA.

RICH as our store of imposing Cattleyas now is the time has not come, and is probably far distant, for any meritorious novelty to lack appreciation. All are welcomed with almost as much interest as though no other good member of the genus were possessed. *C. Rex*, *C. Alexandrae*, and *C. Victoria Regina* have, each in its turn, passed before the search-light of expert criticism and received judgment. They are followed by another very fine and distinct form, which made its bow to the public on September the 6th, when it was submitted to the Orchid Committee of the Royal Horticultural Society by Messrs. Sander & Co., and received a first-class certificate. The new comer is named *Oweniana*, and is of exceptional beauty. The flowers are of great size, and are very richly marked. The lip is very long, broad, and somewhat flattened at the apex, which is very rich velvety crimson. It narrows somewhat towards the throat, and the basal portion, together with the side lobes, which close without folding, are deeply veined with gold. This combination is unquestionably a very striking one, and there can be no hesitation in classing *Oweniana* as one of the most beautiful Cattleyas yet seen.

The mystery in which dealers consider it necessary, for trade purposes, to enshroud their novelties precludes the possibility of acquiring any definite information about the plant, and we are left with an abundant crop of conjectures to quench our thirst for knowledge. It is hinted more or less vaguely that it may be a natural hybrid. Exactly, it may be. Then it is further suggested that *C. gigas* and *C. aurea* may have had something to do with its production. This may be true also. There is much similarity to *C. aurea* about it, and there is a *C. gigas* habit of growth. Specialists must draw their own conclusions from an observation of the points of the novelty, and a comparison with those of other known species. We give an engraving (fig. 33) of the new *Cattleya* for the benefit of those who missed seeing it at the Drill Hall.

ODONTOGLOSSUM HARRYANUM.

THIS very fine and distinct species is one of the most welcome of the comparatively recent additions to a genus already well represented in our glass houses, and runs *O. grande* hard for the first place among the late summer and early autumn-flowering *Odontoglossums*. The pseudo-bulbs are more or less oblong, deeply compressed, 3 inches long, sometimes longer. The oblong, obtuse leaves are of good substance, reminding one of *O. grande*, but longer. The scape is 14 to 16 inches long, stout, almost erect, many flowered. The flowers are 3 to 3½ inches across; the sepals oblong, acute, reflexed at their apex in some examples, while others have a decided tendency to curve inwards, basal half traversed the remaining length with closely set broad lines of mauve-purple on a white ground; central area a fine brown, tip dull yellow. The lip is oblong, more or less oval, three-lobed, side lobes turning upwards; they have the same colour and markings as the lower half of the sepals, and are sometimes of a lighter tint; the anterior lobe sub-cordate, acute, white or pale yellow; the crest is fine yellow, fimbriate; column pale yellow, merging to white, winged.

Capital examples of this species have been in fine flower in the collection of John F. Hall, Esq., Sharcombe, Wells, Somerset, for some time past, and are still fresh.—W. R. W.

ANGRÆCUMS.

ALTHOUGH some genera of Orchids produce more showy flowers and more glowing colours than the *Angræcums* do, yet there are hardly any which attract so much attention from the general public when they have the opportunity of seeing them. The purity of the white in most species, the peculiar long tail or spur dependent

from each flower, and the delicate fragrance emitted, all tend to make *Angræcums* favourites with horticulturists and lovers of flowers. The size of the plants varies considerably, from *A. eburneum*, 3 to 4 feet high, with long stiff leaves, to *A. falcatum* 1 to 2 inches high, and from the large prominent flowers of *A. sesquipedale* to the tiny ones of the little known *A. distichum*.

Being natives of Madagascar, South Africa, and the Gold Coast, it will be readily seen that to insure good cultivation a high and moist temperature is required. The East Indian house suits them well. The stronger species may be grown in pots and the smaller ones in baskets, using only sphagnum and crocks. They should never be allowed to get dry.

The following species are about the best in the genus:—*A. articulatum* has thick, light green leaves, about 4 inches long. The plants are seldom more than 6 to 8 inches high. The pendulous racemes are about 15 inches long, with two rows of pure white flowers, each 1 inch across; spurs 3 inches long. It was introduced from Madagascar by the Rev. W. Ellis.

A. caudatum grows about a foot high; the leaves are about the same length, broad, close together, and divided at their apices. Racemes four to six flowered, 18 inches long; the flowers are 2 to 3 inches across. Sepals and petals narrow, green; lip white and pointed; the tail often measures 9 inches in length, and is pale green. Introduced from Sierra Leone by Messrs. Loddiges in 1834.

A. citratum is a dwarf species, very interesting and pretty. The leaves are more ovate than most species, about 4 inches long by 1 broad. The racemes are 12 to 18 inches long, pendulous and crowded with small straw coloured flowers; the spur is short, thickened and transparent at the end. Native of Madagascar.

A. eburneum is a strong growing species, with leaves 2 feet in length. The racemes are stiff, erect and often 3 feet high, bearing about a dozen flowers each 3 inches across; sepals and petals green, the lip ivory white, the spur is about 3 inches long. It is supposed to have first flowered in Europe at the Royal Horticultural Society's Garden at Chiswick in 1832, being introduced from Madagascar.

A. fastuosum is a beautiful little plant with dark green leaves about 2 inches long; the flowers are pure white and deliciously fragrant, each about 1½ inch across. It was discovered by M. Leon Humblot, and introduced by Messrs. Sander & Co. in 1881.

A. Kotschyi prefers to grow on blocks, and produces very long roots freely. The leaves vary in size, and are dark green. The quite pendulous racemes produce several pure white flowers, each about an inch across; the spur is particularly noticeable, being about 8 inches long, twisted and reddish. Native of Zanzibar. Discovered in 1838.

A. Leonis was described and figured in the *Journal* of June 2nd.

A. Scottianum was introduced from the Comoro Islands in 1878, and first flowered in the collection of Mr. Scott of Walthamstow, after whom it was named. The stems are slender, terete, and dark green; leaves 6 inches long, recurved, grooved on the upper surface. The flowers are usually solitary, though sometimes produced in pairs; the sepals are greenish, petals white, lip large and white, spur pale yellow green, 5 inches long.

A. sesquipedale was introduced from Madagascar by the Rev. W. Ellis in 1855. The leaves are close set and thick, dark green, and divided at the apex. The flowers are about a foot across, ivory white, with a tail about 12 inches long. They are produced during the winter months, and are exceedingly attractive.

A. Sanderianum is a charming plant, flowering regularly every spring. The drooping racemes are 1 foot long, and bear many of the pure white flowers each 1½ inch across; the spur is about 3 inches long. Native of Madagascar.—C. K.

JOTTINGS ABOUT LONDON PARKS.

BATTERSEA PARK.

THIS is recognised as being the most picturesque park within the metropolitan area, and it is here one naturally expects to see good flower gardening. There are sufficient contrasts and harmonies of colour and form to suit everyone. Here we find carpet beds—prim, formal, and fantastic in design; there a bed rugged in outline. In addition to these features there are the sheltered nooks filled with sub-tropical plants, the beautiful borders of mixed flowers, the bold masses of shrubs, winding walks, and a splendid lake, in which Water Lilies are now flowering profusely.

It is, however, the summer bedding that interests us most at present. Although, on the whole, a fair summer, this has not been a particularly favourable season for tender bedding plants. In some places the plants have done well, whilst in others the display is below the average. This is noticeable in Battersea Park. Two of the carpet beds in the sub-tropical garden are exceedingly good this year, the *Alternantheras* being

particularly bright. Perhaps nowhere could better-kept beds be seen, the plants being apparently nipped and so restricted in growth as to be absolutely faultless in outline. But are such beds desirable? That they are wonders in their way is readily admitted, and they reflect great credit on the designer, but one cannot help regretting that a more natural system of flower gardening is not generally adopted in such a beautiful park. The longer we look at these combinations of colour and stunted plants, the greater the relief when we turn to beds less formal in outline. Of the latter there are happily a great variety.

In the sub-tropical garden there are many beds that are remarkably striking and pleasing in effect. One planted with bold specimens of *Gunnera scabra* and *Polymnia grandis*, and edged with variegated *Pelargoniums*, and *Sempervivums*, is particularly effective. In a suitable position an imitation of this could be made with advantage. A bed of single Tuberous *Begonias*, with a ring of yellow-leaved *Pelargoniums*,

Delphiniums, *Dahlias*, *Gladioli*, *Musas*, *Eucalyptus globosus*, and other hardy and half-hardy plants. This is the kind of bedding that is required in such a picturesque park. Bold masses of *Cannas* near by are likewise conspicuous, and the same may be said of a bank of *Fuchsias*, one mass of bloom. Specimens of *Araucaria excelsa* are used with good effect in one or two beds, and some huge plants of *Brugmansia Knighti* catch the eye, but these have not done well this year. There are also numerous beds filled with *Pelargoniums*, *Lobelia*, *Coleuses* and other ordinary bedding plants in the customary manner, and which for the most part are now past their best.

Although the principal feature, the sub-tropical garden does not constitute the whole of the bedding in Battersea Park. There are, besides the beds mentioned, borders and nooks filled with a variety of plants, all interesting and effective. From a natural point of view, perhaps one of the most attractive corners is that leading from the

FIG. 33.—CATTLEYA OWENIANA.

and edged with blue *Lobelia* and *Mesembryanthemum*, is also noticeable; whilst in the background a bold mass of dark-leaved *Cannas* shows up conspicuously. Among the latter some rich scarlet *Gladioli* spikes are most effective. Those who favour a quiet arrangement would be interested in a bed planted with *Vitis heterophylla variegata*, above which rise spikes of *Lobelia Queen Victoria*, the dark foliage and scarlet flowers making a pleasing contrast to the variegated leaves of the *Vitis*. This bed is edged with variegated *Pelargoniums*, pink *Lobelia*, and *Mesembryanthemum cordifolium variegatum*. Near to this, but in the background, a row of white *Phlox* shows up conspicuously against a number of dark-leaved *Castor Oil* plants.

Rather an uncommon bed is that of Tuberous *Begonias*, amongst which green and red-leaved *Dracenas*, and *Dieffenbachias* are planted. The latter, however, do not seem particularly happy in their quarters, possibly owing to the recent cold winds. Still, the bed is novel in its arrangement, and was doubtless attractive earlier in the season. A large bed planted with *Wigandia caracasana* associated with a dark *Heliotrope* and edged with bands of *Iresine*, variegated *Pelargoniums*, blue *Lobelia*, and *Echeverias*, also attracts attention, not only for its appearance but fragrance, the *Heliotrope* being most delicious. I noted with pleasure, too, a large mixed bed, amongst which were

sub-tropical garden and near the lake. Here we find banks, irregular in shape, planted with various hardy and other plants. Amongst these are *Liliums* of sorts, *Lobelia Queen Victoria*, *Salvia patens*, and large clumps of *Thalictrum adiantifolium*, the whole making a charming display. The groundwork in the front, or rather at the base of the mounds, is planted with *Pilca muscosa* and *Sedums* of different kinds. The only drawback, to my way of thinking, to this arrangement is the manner in which the *Liliums* are disposed. It would have been better had they been planted in bolder masses. The borders, of which there are many in different parts of the park, are just now gay with autumn flowers, these being really more showy than the beds. Masses of *Helianthus*, *Phloxes*, *Gladioli*, and various annuals, such as *Asters* and *Stocks*, are exceedingly bright, showing up well against the background of shrubs. Much more could be written anent the floral arrangements there, but it is sufficient to say that the characteristics of this charming park are fully maintained this year, and a visit may with advantage be paid before frosts destroy the effect.

VICTORIA PARK.

This park has long been noted for good flower gardening. Although situated in a by no means salubrious neighbourhood, the beds are

usually of a bright and interesting character, and this year they are no exception to the rule.

In this, as in the other parks noted, a change in the style of bedding has taken place during the past few years, but the carpet system here still retains a good hold. Much may be said for as well as against carpet bedding, for although not now generally appreciated it must be admitted that when properly done it affords evidence, if nothing else, of the high development of a gardener's skill. In Victoria Park the carpets are really good, and perhaps they never looked better than at present. When the flowering plants are covered with bright bloom the colours of the foliage of those used in carpet bedding pale; but as soon as the former begin to fade, the latter appear to advantage. Such was the state of things in this park during the latter part of last week. The majority of the Pelargoniums and other ordinary bedding plants are past their best now, notwithstanding the attempt that is being made to prolong the display by the removal of faded blooms. But the carpet beds are really worth a visit. The designs are good—not too fantastic, and the colours are charmingly arranged. The Alternantheras are particularly bright, and the white foliage of Cineraria maritima shows to advantage in many beds.

Near the entrance from the Victoria Park Road there is a grand circular bed of Pelargoniums, variegated and zonal, planted in triangles. In the front of these there are triangles of Golden Treasure Fuchsia, the centres being filled with Coleus Verschaffelti. The whole arrangement is edged with blue Lobelia and Echeverias. Pelargoniums have evidently been very fine, but Tuberous Begonias do not appear to have done well. Mixed beds are numerous, and among them hardy plants are noticeable, several fine clumps of Anemone japonica alba showing up well. This grand autumn blooming plant should be more extensively used for bedding purposes.

Another conspicuous feature in this park are the beds of succulents. One arrangement of this kind is particularly effective. It is a large circular bed in the centre of which is a fine Agave, similar plants of a less size being set at equal distances over the bed. Between these are succulents of various kinds, the groundwork being Mesembryanthemum cordifolium variegatum; a fine edging of Echeverias completes the display. Several banks near the ornamental lake are similarly planted; the ground in the front portion is, however, occupied by Antennaria tomentosa. Sub-tropical plants are good, and several arrangements of these near bright carpet beds form a splendid contrast.

The borders of hardy flowers deserve a word, though these are not so numerous as they might be. Still, the few that exist are now gay with autumn flowers, comprising masses of perennial Sunflowers, Chrysanthemums, and annuals of kinds. On the whole the display in this Park is quite up to the usual standard, and fully maintains the reputation it has so long held for effective bedding.—C. C.

REVIEW OF BOOK.

Fruit Culture. By J. CHEAL, F.R.H.S. London: G. Bell & Sons, York Street, Covent Garden.

WE take from our pile of books, some of which have waited long for the attention they merit, Mr. Cheal's handy and useful volume on fruit culture, and a reference to it at the present time will not be inopportune. It is included in Messrs. Bell & Sons' agricultural series, and fittingly has a place amongst them, for fruit-growing must be more distinctly recognised in the future than it has been in the past as deserving the attention of cultivators of land, whether on a large or comparatively small scale. As nothing can so well indicate the character of a book as a few citations from it we will let the work speak for itself. British neglect and American enterprise, as well as the prospective supply and demand for fruit, are treated as follows:—

Our own cultivators, or rather possessors of orchards which have to a great extent been uncultivated, are in the meantime crying out that they cannot sell the Apples that they already grow; but the reason of this is not far to seek. The Apples sent to market from these orchards will be found in most cases to be such a mixture that the housewife can find amongst them any sort except the ones she needs, and they appear to have had in gathering the treatment by the farmer that Talpa recommended him to give to his clods, in the old book "The Chronicles of a Clay Farm:"—

"Mingle, mingle, mingle, all ye who mingle may,
Blue spirits and white, black spirits and grey."

This treatment is all right for the clods, but all wrong for the Apples.

The American orchardists have seen their opportunity, and taken it. They have noted the requirements of our markets and have set themselves to work to meet those requirements, and they have by careful study and scientific practice been able to produce and place upon our markets thousands and tens of thousands of bushels of Apples of good quality, especially handsome in appearance, regular in size, and uniform in quality. These find a ready sale, not only in large cities but also in our provincial towns, and even in our country villages, at the very doors of those who could grow just as good themselves, and who are perhaps complaining of bad times, and the hopelessness of making corn growing pay.

But the responsibility for this state of things is by no means confined to the farmer, the lethargy of the landowners with respect to this matter

is unaccountable. They have been standing still with their tenants, and supplying themselves with fruit from across the water instead of from their own lands.

Apples that can be produced of such handsome appearance and placed on our markets in such fine condition are sure to sell, and people will continue to buy until we can supply them with a sufficient quantity of better fruit at home. And that the quality of our fruit, of the best varieties, when grown with care and scientific skill, is superior to that from over the water is abundantly proved by the much higher price invariably realised for such fruit. Highly coloured skins do not always indicate the highest quality inside, and most of the American fruits are dry and woolly compared with the juicy lusciousness of our own prime English fruit. The moral obviously is, that those who grow the fruit must produce the highest quality. The fruit must be *cultivated*, and not allowed simply to *grow*.

That a movement has set in in this direction is very evident, as shown by the agricultural returns of fruit planted in this country, which exhibit an increase during the last two years to the extent of 12,000 acres, as against a decrease in the previous year of 500 acres; so that pessimists are beginning to say, "Ah, yes! now it will be overdone;" but there is no prospect or possibility of this for many years to come. With the increase of supplies of good fruit the consumption will extend enormously, and the supply will create further demand. As a proof of this take the case of Tomatoes. The consumption of these twenty years ago was confined to a very limited number, but now that people have become educated to their use and have discovered their wholesome qualities, they are in daily demand by the million, and their growth has probably increased a hundredfold during that period. An interesting calculation in the "Country Gentlemen," an American organ, as to the quantity of fruit that might and ought to be consumed by the people is given as follows:—

"Each member of every family should have on an average 1 lb. of fruit daily—some will eat more some less—either fresh or cooked. How many pounds will that be in each day? There are 40,000,000 persons in the whole country old enough and well enough to eat fruit, which would be 40,000,000 lbs. or nearly 20,000 tons daily consumption. Taking the year through it would amount to 7,000,000 tons. The daily consumption of fruit would prevent many persons from eating or imbibing what is much worse, and at the same time it would contribute greatly to health and prevent disease. We want more enterprise, skill, calculation, and management to raise and properly distribute these 7,000,000 tons."

Then the author goes on to utter words of caution and of warning against too great expectations from rushing hastily into fruit-growing. He says:—

Those who enter upon fruit culture must not, however, expect to make fortunes in a year. Much has been said and written which is wide of the truth as to profits—so wide indeed that it does much harm instead of good. Exaggeration and over-statement only weaken the argument and raise suspicion, and ultimately lead to disappointment, in those who listen to and act upon it. But there is abundant proof that those who plant carefully, and cultivate with common sense, to say nothing of scientific skill, reap a fair return for their outlay and labour. This is proved, not merely by large growers for market but by a considerable number of small cultivators. . . . But many points will have to be thought out and determined before even commencing. There will be the question of whether you have a retail outlet for your fruit, or whether it must be sent to a wholesale market, whether you would be likely to get a better return for early or late varieties, and whether you have a jam factory or other means of disposing of the fruit. All these considerations would have a bearing upon the varieties to plant, and upon the general arrangement. These points being determined by the intending grower he should then select his position accordingly, or if this is already fixed, he will determine his action from his surroundings. Then let him steadily pursue his purpose and not be daunted or turned from it by the first or second failure; but having made sure that he is on the right course, go steadily ahead.

Discussing the system of land tenure, which has proved the reverse of encouraging to the planting of fruit trees, Mr. Cheal writes:—

The most satisfactory arrangement seems to be for the landlord to find the trees and the tenant to find the labour, and prepare the ground for planting. It is, of course, to their mutual interest to select good trees of the right varieties, and to plant and cultivate them properly. It is also especially to the interest of the tenant to maintain and cultivate them well, in order to realise the best return from them in the shortest possible time, and he will be naturally anxious to continue his tenancy as long as possible in order to reap the full benefit of his first outlay; and the landlord is thus likely to secure a good thriving tenant, and to see his property considerably increasing in value. There is then at the expiration of the tenancy no vexed question respecting valuation and compensation.

An instance came under my notice a short time since of a landlord who some years ago expended about £20 an acre in planting Apples for a tenant, upon land which previously let for £1 per acre. The land has now for many years been let at £4 per acre, whilst the land adjoining is still let for £1 per acre. Therefore the £20 outlay in planting fruit has yielded to the landlord £3 per annum, which is not a bad interest on the outlay, to say nothing of the largely increased

capital value. I think, if carefully looked at from a landlord's point of view, it will be seen that it is not only the duty but the interest of landlords to give every facility that they legitimately can to good tenants as regards this matter of fruit culture.

We take one more extract, dealing with what we term the accelerating of profits in fruit culture. No doubt our author likes these to be as quickly produced as possible, and as he is not a selfish man, is imbued with the same desire for others, hence remarks:

One great drawback to fruit culture in the past has been the time that must necessarily elapse after planting before realising a return. According to the old methods it was useless to expect anything like a profitable return from fruit trees for at least ten to twelve years after planting. Modern science and practice have, however, done much to alter this. Necessity in this case, as in many others, has stimulated invention, and by the use of dwarfing stocks and other similar means almost a revolution in fruit culture has been accomplished. Many of our Apples for which we had to wait years for a crop will, by working on the Paradise stock, now yield fruit the second season after grafting; and what the Paradise has done for the Apple the Quince has done for the Pear.

What was said of the Pear, according to the old lines is now changed into the following:—

"That 'Those who plant Pears
Grow fruit for their heirs,'
Is a maxim our grandfathers knew.
But folks have learned since,
If you graft on the Quince,
The fruit will develop for you."

We hope that many readers will realise the truth of the prophetic utterance, as they may if they discriminate, for there are a few Pears that are the least profitable in the end on Quince stocks. One instance is afforded in the Pear garden of Mr. Thomas of Sittingbourne. His Pitmaston Duchess Pears on free stocks are the most profitable of all his varieties, and we are well within the bounds of strict accuracy in stating that any one of his trees on the Pear stock has given a greater value of fruit during the past fifteen or twenty years than have three on the Quince, and we could cite other examples. There is plenty of sound information in the book to enable "fruit to develop" for the growers if they follow intelligently the methods advised in land preparation, planting, pruning, and the selection of appropriate varieties for the positions and object in view. The work is well printed, usefully illustrated, and is worthy of being associated with other handbooks on the subject—hardy fruit culture—on which it treats.

ALLERTON TOWER.

THE residence of Sir Thomas Earle, Bart., is a fine imposing mansion and is about ten minutes walk from Allerton Station on the L. and N.W. Railway. It is situated in charmingly wooded grounds, from which at nearly every turn beautiful and varied views present themselves; whilst from the tower and south side of the terrace the river Mersey can be seen for a long distance, with its numerous array of ships sailing to and fro from all parts of the world. The house is approached by a winding drive, along which are some fine old trees, and, what are so seldom found in this neighbourhood, two large Mulberry trees, which are every year laden with fruit. A short turn through a walk bordered on each side by Rhododendrons, and we are on the terrace. Here we get a grand view of the pleasure grounds, the features of which are the perfectly kept lawns so free from all kinds of noxious weeds. The walks are quite straight, and have been evidently made to match the architecture of the house. The lawns stretch away in the distance, and here and there fine old trees are to be noticed, together with banks of shrubs.

The flower garden, although small, is very tastefully bedded, and it is just as well that it is no larger, or much of the delightful effect of the terrace view would be entirely spoiled. On the left of the terrace is a small conservatory, leading into a long corridor. The outside of the corridor is festooned with creepers, but what impressed me most was a fine old Vine, running the whole length immediately underneath the roof. This not only proves ornamental when in active growth, but as autumn turns the green leaves into purple and crimson and gold, its usefulness for decorative purposes cannot be over-estimated. Much more might be done with outside Vines in respect to the foliage, thereby saving the partial destruction of many Vines under glass, which in some cases have to have many of the leaves stripped for use in garnishing dishes of fruit throughout the autumn and winter.

Passing from the terrace, down a flight of stone steps, we come to a broad gravel walk, on each side of which are planted three fine specimen Irish Yews. A turn through a doorway and we are brought into the quarter where the plant houses, vineries, and Peach house are situated. The first we enter is a greenhouse filled with a splendid assortment of plants appropriate to such a structure. Particularly attractive were the Fuchsias trained up the roof. The next house is a stove and fernery combined. A grand Allamanda Hendersoni in full bloom occupied a large space on the roof, and good plants of Asparagus plumosus, useful Ferns, and table plants covered the stages. The vinery is in three

divisions. In the early one the heating is not sufficient, and to counteract this Mr. Stoney, the gardener, has the ropes removed and the ventilating sashes nailed down, so that not a breath of air is admitted until April. How well this succeeds is shown by the magnificent bunches of Muscats and Madresfield Court, which have taken high honours at the Liverpool Show over a period of years. The second vinery has four Black Hamburgs, two Muscats, and one Madresfield Court. This again has only a flow and return pipe running through, and those who cling to the impression that Muscats are never satisfactory in a mixed house, and that they want so many degrees of heat more than other Vines, would have it shaken could they see what is done at Allerton. In the centre of this house a chamber is built, which is entered by a small door. Here is done all the Mushroom growing and the forcing of Seakale and Rhubarb. The late house is planted with one Bowood Muscat, three Lady Downe's, and three Alicantes, and the same splendid crops are to be seen. The centre portion of the flooring in this house is always occupied with Camellias in pots, which at the time of my visit were so thickly set with buds as to necessitate the removal of some hundreds of them. Before closing reference to the Vines I may also add that the magnificent collections of vegetables exhibited with such conspicuous success year after year at Liverpool are grown on the outside Vine borders, and apparently with not the slightest detriment to the Vines.

Passing along a small walk, bordered on each side by herbaceous plants, we come to the fine Peach house, which is 300 feet long and in three divisions. The first house has the trees on the back wall only, the front being filled with miscellaneous greenhouse plants. The varieties in this house are Teton de Venus, a fine Peach, of good colour, and with excellent cropping qualities, but one seldom met with, and Grosse Mignonne, Improved Downton, Pineapple, and Lord Napier Nectarines. In the second division on the front trellis is a stately old Royal George Peach. It covers a space 30 feet in length, and the stem 1 foot from the ground is 27 inches in circumference. It never fails to carry a crop of from 250 to 300 fruits, and all of the finest quality. The others on the front are two Bellegarde, carrying superb crops, and Noblesse, which is Sir Thomas Earle's favourite Peach. On the back are two Stirling Castle, Alexander, Dr. Hogg, and Violette Hâtive and Victoria Nectarine. The late house is without fire heat, and consists of the following on the back wall:—Walburton and Late Admirable, Royal George, Barrington, Noblesse, Balgovan, and Victoria Nectarine. A few cordon Pears are planted between of the following varieties, all carrying good crops:—Jargonelle, Williams' Bon Chrétien, Hassle, Pitmaston Duchess, Marie Louise, Brockworth Park, Doyenné du Comice, Duchesse d'Angoulême, and Josephine de Malines. Along the front are Plums planted out. The chief sorts are Coe's Golden Drop, Purple Gage, Green Gage, and Jefferson, all free from insects, and carrying fine crops. I may here mention that with the exception of one or two young trees, none of the other Peaches and Nectarines has been lifted for ten years. A hard surface, a good mulching of decayed manure during the fruiting period, free watering, and training the shoots thinly are the means by which such excellent crops are produced throughout the entire range.

A few old-fashioned forcing pits, used firstly for the forcing of early Potatoes and the propagation of bedding plants, were filled with splendid crops of Lockie's Perfection Cucumber and Masterpiece Melon, and in another was an old Stephanotis, which is never out of flower, and which was a perfect sheet of lovely wax-like flowers. There is also a rosery in the pleasure grounds, which was very gay. In the vegetable department the crops are excellent. There is not a foot of spare ground, and what is more not a weed to be seen. There is also, a short distance from the house, a finely cropped garden of vegetables some 100 yards long by 22 feet wide. Considering the number of hands employed in the gardens it is nothing short of wonderful that the whole of the grounds are kept in such a thorough manner. Mr. Stoney's courtesy has earned him hosts of friends.—R. P. R.

HORTICULTURAL SHOWS.

SHEFFIELD, HALLAMSHIRE, AND WEST RIDING UNITED CHRYSANTHEMUM SOCIETY.

THE second annual summer Show of this Society was held in the Museum, Orchard Street, Sheffield. As compared with some of the district exhibitions held in tents this display of plants, flowers, fruits, and vegetables was small, and lacked some of their interest; but upon the whole it was a creditable display, and serves a useful purpose in drawing attention to the main objects of the Society, which are to cultivate energy and enthusiasm among all classes of Chrysanthemum growers, and endeavour to enlist their support as well as that of the general public for the November Exhibition. This summer Show gives many supporters of the Society, who are not Chrysanthemum growers, an opportunity to compete for small prizes given for other plants and flowers at a time of the year when outdoor flowers and many kinds of vegetables and fruits are fairly plentiful.

The response accorded by the amateur members of the Society was most praiseworthy, especially in the classes devoted to herbaceous Phlox, Gladioli, Dahlias, Stocks, and Asters. These flowers were all numerous and well shown by the amateurs, far exceeding in quality those in the professional classes, where competition, except in those for vegetables, was only weak. The display of plants was very poor, doubtless owing to the soaking wet weather of the first day, and the objections which some had to a two-days show. The frequency of exhibitions at the time

in the various outlying districts served also in deterring many from competing. The chief prizewinners in the professional class were Mr. T. Hanley, who was first with Grapes, Peaches, stove and greenhouse flowers, hand bouquet (a very good example), six buttonholes; Peas and Beans. For six Roses, dissimilar, Mr. T. Allis was first, as he also was with Asters, Tomatoes, and a splendid brace of Cucumbers. Mr. R. Howarth was first with Stocks, Fuchsias, and table plants; Mr. T. Brewer with exotic Ferns, single Dahlias, and an epergne of flowers; and Mr. J. Thompson with Pompon Dahlias. For a British Fern Mr. T. Ball was first, and specially commended for a large plant in a 9-inch pot of a seedling *Athyrium filix-femina ramo-cristatum*, raised by himself. The plant was three or four years old, a most vigorous specimen, and considered to be an exceedingly good crested variety.

In the amateurs' section the keenest competition took place in the classes for cut blooms. For six spikes of herbaceous Phlox Mr. W. Willgoose was first against five competitors, as he also was with Asters, beating twelve opponents, all staging blooms of good quality. He was also placed first for a stand of blooms, dissimilar, outdoor grown, for three Pompon Dahlias, and for Beans. Mr. R. Gascoigne was first with three spikes of splendid Gladioli and six Tomatoes. In the class for Stocks there were ten exhibitors, all with excellent single spikes, but the first prize lot staged by Mr. W. Jackson was decidedly superior in size of spike and individual blooms, with erect appearance. Mr. W. Fletcher was second with little less inferior spikes, while Messrs. W. Willgoose and C. Furniss were equal thirds. For six blooms, greenhouse flowers, Mr. G. Walker was first, he also taking the leading place with a choice hand bouquet, tastefully arranged; one plant in bloom, a large Fuchsia; one Gloxinia; and one foliage plant (a splendidly grown *Caladium*). Mr. W. Carlton had a stand of superb Pansies for which he was placed first. In the class for three Show Dahlias eight exhibitors competed very closely, the leading position being obtained by Mr. W. Adams, second Mr. A. Jones, third Mr. R. Smith. For three Roses Mr. C. L. Wright was first. Mr. J. Eadon took first place in the British Fern class with *Osmunda regalis* in a 14-inch pot, and Mr. W. Housley was second with *Polystichum angulare*. In the exotic Fern class Mr. W. H. Hinchcliffe was first with *Pteris serrulata cristata*, a bushy specimen. Other first prizewinners not mentioned were Mr. G. Hancock (brace of Cucumbers), and Mr. H. Broomhead (brace of Celery, splendid, well-blanchet, clean examples). Mr. Broomhead also exhibited, not for competition, two plates of large Gooseberries.

HORLEY.—SEPTEMBER 7TH.

RATHER late in the year was it for the Committee of this south-east Surrey Society to venture upon an outdoor Exhibition, but as so many held earlier had come to grief through bad weather, it was not perhaps so dubious a prospect after all. The afternoon proved damp, something of a Scotch mist falling, but it hardly damped the energies of the local people; whilst the evening from five o'clock was fairly fine, and the attendance was large. The Show was held in a huge tent in a sort of public field, where there was ample room for the sports and other pastimes indulged in, and no effort was spared to render the day one of many attractions, as should be the case in these rural districts. Within the tents there were numerous exhibits of an honorary nature that merit notice. The trade was represented by a capital group of plants sent by Messrs. Peed & Sons, Norwood. This collection included some very fine Cockscombs. This firm also showed a good lot of Dahlias. Messrs. J. Cheal & Sons, Crawley, set up a good collection of Show, Cactus, Pompon, and single Dahlias in their usual attractive style; and Mr. R. Spinks, a local florist, had a large collection of Cactus and Pompon Dahlias.

From private sources came first a beautiful group of plants from Mr. Cottle, gardener to W. Tebb, Esq., Rede Hall, Burstow; a very fine one from Mr. Sanders, gardener to H. White, Esq., Horley, including some good Begonias; and smaller ones from Mr. Ratley, gardener to Captain Charrington, and Mr. A. Woodman, gardener to Colonel Farebrother. Mr. Tickner, gardener to J. Walker, Esq., had the best decorative group in competition—a very neatly arranged one; and for flowering plants had some capital Chrysanthemums with fine blooms, Bouvardias, Gloxinias, with excellent foliage plants and Ferns. Mr. Sutton, gardener to J. H. Donaldson, Esq., was second. Mr. R. Cornford, gardener to J. Whitchurch, Esq., was first with six medium-sized but very richly coloured Coleuses. Mr. Sanders had the best Begonias, really well-flowered plants; and Mr. Cornford the best six Cockscombs. In cut flowers there was a capital competition in the class for eighteen bunches of any varieties, Mr. Coutts, gardener to J. W. Stevenson, Esq., having the best with very neat prettily arranged flowers. Mr. Tickner, who was second, had large bunches of good flowers, but indifferently arranged. Mr. Sutton had the best twenty-four Asters in really good Victorias, and Mr. Sanders the best six bunches of Cactus Dahlias. Other cut flowers were very good.

Of fruit the best pair of bunches of black Grapes, beautifully finished Lady Downe's, came from Mr. Sutton, Mr. Cornford being second with fair Hamburgs. Mr. Sutton was again first with two fair bunches of Muscat of Alexandria in the class for whites, Mr. Batty being second with Buckland Sweetwater. Mr. Cornford had six good dishes of fruits in very fine Raspberries, Morello Cherries, Peaches, Plums and Apples. Mr. Catt, gardener to E. S. Miller, Esq., was second.

Mr. Coutts had the best Tomatoes; moderate sized, but otherwise perfect samples of Perfection. In a class for six vegetables, prizes offered by Messrs. Sutton & Sons, Reading, Mr. W. Greenfield, a local

amateur, was first with excellent Best of All Potatoes, Prizewinner Runner, and Canadian Wonder Beans, Long Surrey Carrots, good Onions, &c. Mr. Sutton was second with good Tomatoes, Carrots, Cucumbers, Excelsior Onions, and rather coarse Cauliflowers. In a similar class for prizes offered by Messrs. Cheal & Sons, Mr. Sutton was a good first, having Satisfaction Potato, Excelsior Onions, Long Surrey Carrots, &c. Mr. Sanders was second with excellent examples. In the Society's class for nine varieties Mr. Greenfield was again first, and Mr. Sanders second. A very good collection of vegetables and fruit was shown by Mr. Ratley. The cottagers' classes brought large and excellent competition. During the evening Mr. Dean, representing the Surrey County Council, addressed a very large gathering on horticulture, dealing specially with the exhibits in the various vegetable classes. W. Cubitt, Esq., M.P., presided, and later presented the prizes to the various successful exhibitors.

DERBY.—SEPTEMBER 7TH AND 8TH.

THE annual Exhibition was held in connection with the Agricultural Society in the grounds adjoining the Cattle Market. Three large tents were well filled with exhibits, and all agreed that the Exhibition was superior to any that has been held in previous years. This change is doubtless largely due to the interest taken in the Show by Mr. Innis and other leading horticulturists in the vicinity of Derby, who have endeavoured to advance it to the front rank of provincial Exhibitions. It is satisfactory to note that their efforts so far have proved successful, and were highly appreciated by the thousands who visited the Agricultural Society's grounds. The horticultural portion was perhaps the chief attraction. The schedule provided no less than 126 classes, which were divided into five sections. The first was open to nurserymen and gentlemen's gardeners, and comprised thirty-five classes. These will be mainly dealt with in the following notes. The remaining classes were devoted to amateurs, children, and ladies. It may be said that the exhibits in nearly every case were highly creditable and most praiseworthy.

Stove and Greenhouse Plants.—These were not numerous, but those staged were good. In the class for twelve plants, ornamental and flowering, arranged for effect, not to include more than two Ferns, Mr. Cypher, Cheltenham, deservedly took the lead, staging splendid examples in his well known style. Mr. Mould, Pewsey, creditably gained the second award. The first collection contained *Lantana borbonica*, *Kentia Forsteriana* (good), *Kentia australis*; *Crotons Countess* (good), *angustifolium* and *Sunset* (large, well coloured); *Ericas Austiniana*, *Marnockiana*, *Turnbulli*, and *Uriana superba*, also a good *Statice profusa*. In the corresponding class for gentlemen's gardeners Mr. Finch, Coventry, took the lead with a capital lot of plants, amongst his best being *Cycas circinalis*, *Kentia Forsteriana* and *K. australis*, *Crotons Sunset* and *montefontaineensis*, *Ixora Duffi* (very fine), a well-flowered plant of *I. Williamsi*, *Clerodendron Balfourianum*, *Stephanotis floribunda*, and two good *Ericas*, *Marnockiana* and *Turnbulli*. Mr. Vere, Allestree Hall Gardens, Derby, was a good second; Mr. Gilbert, gardener to Rowland Smith, Esq., Duffield Hall, third; and Mr. A. Webbe, Kelham Hall, Newark, fourth. For the best arranged basket of plants there were only three exhibitors. Mr. J. Ward, gardener to T. H. Oakes, Esq., Riddings House, was first; Mr. Vere, gardener to Sir Wm. Evans, second, with a heavier, rather crowded arrangement; and Mr. Webbe third.

Groups.—Three prizes of £12, £8, and £5 were offered for a group of plants covering a space of 200 superficial feet, to include stove and greenhouse flowering and foliage plants, the points of merit to be the specimens and the arrangement for effect. This class was open, and first included in the schedule in 1886, but discontinued after 1888 until the present year. Although only three competitors staged groups the class is worth retaining in the schedule, as the exhibits added materially to the beauty of the Exhibition and attracted considerable attention. The space devoted to them was wedge-shaped. Mr. Ward was well first with an arrangement that was light, effective, and highly artistic. It consisted of about a dozen little groups, the back one having for a centre a *Kentia*, the two next *Eulalias*, the two next *Cocos Weddelliana*, a centre one *Croton Warreni*, two others the same plant, while the front ones of smaller size were principally Palms. Each group was an attraction in itself, and was lightly filled up with plants of a choice nature, while the spaces between were covered with wood moss. In two or three of the winding spaces between the groups plants of *Nepenthes Mastersiana* were arranged on moss-covered stakes. The group had one fault—too many *Crotons* had been used for centre plants. The second prize was obtained by Mr. A. Webbe, and the third by Mr. Morris, Burton Road, Derby. The second group was a most praiseworthy one, and at a first glance had every appearance of securing the post of honour. The arrangement was very tastefully conceived. A good deal of cork was used in its construction, and out of this the main as well as the plants that formed the separate groups were allowed to rise, all the space between being covered with wood moss. From one side this group had a very handsome appearance. Unfortunately, however, too many plants had been used, and gave to what would have been a splendid group a rather crowded appearance, while sufficient was scarcely left to furnish the front properly.

Ferns.—Two classes only were provided for these—one for six distinct kinds, three collections being staged. Mr. Ward took the lead, followed by Mr. Gilbert and Mr. Vere. For six *Lycopodiums* the same number of exhibitors staged plants. Mr. Vere was first with large well-grown examples, Mr. Gilbert being a good second.

Cut Flowers.—These were not numerous, but those staged were, on

the whole, good. For twelve Roses Mr. Robinson, Green Lane, Derby, took the lead with fairly good blooms. For six blooms Mr. Carrington was successful. For twelve Dahlias Mr. Carrington was first with fresh young flowers. Those staged by Messrs. Henson and Robinson, for the second and third respectively, were larger, but displayed signs of decay at the base. For six blooms Mr. R. Shaw was first. For twelve singles (prizes given by Mr. Walter, Derby) Mr. J. Salisbury won. The competition in this class was good, and four prizes were awarded. For twelve trusses of Zonal Pelargoniums, nine varieties, three blooms of each, Mr. Carrington was well first with fine trusses, but not so well staged as those of Mr. Henson, who was a good second. For six double kinds, three blooms of each, Mr. Henson was first, while Mr. Carrington was first for twelve trusses of Verbenas, not more than three trusses of each. Mr. Henson was first for African Marigolds, and Mr. Carrington for Asters. Mr. Robinson gained honours for Gladioli, twelve distinct spikes.

Bouquets were good and the competition keen. For one hand bouquet Mr. Hanson was well first, Mr. Robinson second, and Mr. G. Bolas, Hopton Hall, third. In the corresponding class for ladies Miss Rowley, Green Lane, was first with a very effective arrangement of choice white flowers. For a vase of cut flowers Mr. J. Goodacre, gardener to the Earl of Harrington, Elvaston Castle, won easily with a very light arrangement. Four other exhibits were staged, two of which did great credit to the exhibitors. In the class provided for a dinner table arrangement of plants, flowers, and fruit, 8 feet long by 4 feet wide, open to ladies only, three competitors entered: Mrs. Ormeara was first, and Mrs. Ward, Riddings House, second, the plants in this arrangement being rather too heavy for the size of the table. In the class provided for wreaths and crosses Mr. Rowley, Green Lane, was the only exhibitor, one of each being superb, while a special first prize was awarded to the same exhibitor for a splendid anchor in which dark Pansies formed the chain.

Fruit.—The Grapes were exceedingly good, and the competition for the prizes offered was very keen. For two bunches of Black Hamburgs Mr. J. Campbell, Micklegate, was well first with large bunches and berries superbly finished. Mr. A. McVinish, Lockington, was second with grand examples well finished, but not so large as the others. Mr. Goodacre and Mr. Evans gained third and fourth honours respectively. For two bunches of Muscats, white, Mr. Campbell was again first with large clean bunches of Canon Hall; Mr. Goodacre second with good Muscat of Alexandria, well finished; Mr. McVinish and Mr. Slade, Clumber, third and fourth in the order named, both showing well. For two bunches of any other white Mr. Campbell was again first with large well finished clusters of Duke of Buccleuch, Mr. Goodacre second with Buckland Sweetwater, Mr. Slade third with Duke of Buccleuch, and Mr. Billings, Ham, fourth with Foster's Seedling. For two bunches of any other black Mr. Campbell was well to the fore with magnificent bunches of Gros Maroc, perhaps two of the finest ever staged. Mr. Goodacre was second with the same variety, having examples that would have been considered very good had Mr. Campbell's not been staged. Mr. Evans, Chaddesden, was placed third with large, well finished bunches of Alicante, and Mr. Vere fourth. A special prize was given by Messrs. Innes & Co. for three bunches grown by the aid of their fertiliser, and Mr. McVinish took the lead followed by Mr. Campbell and Mr. Prince; these three exhibits were very praiseworthy.

For two Melons Mr. Ward took the lead, followed by Mr. Goodacre and Mr. Robinson. For six Peaches Mr. Evans was first with a grand dish of Exquisite, Mr. McVinish and Mr. Campbell being second and third. For six Nectarines Mr. Billings was first. For six dessert Apples Mr. Webb was first, and Mr. Read, Brelby, for six kitchen Apples. For a collection of ten dishes of fruit, distinct species, Pine excluded, Mr. Goodacre was first, and staged in his well-known style; Mr. Webb was second, and Mr. J. Evans third. In this class black and white Grapes ought to be allowed. In one or two cases collections had to be left out because they were included.

Vegetables.—It would be difficult to imagine a better display of vegetables. One large tent was well filled on both sides with excellent produce; in fact, part of a second tent was taken up with them. In the class for twelve distinct species some ten or twelve collections were staged. The post of honour was accorded to Mr. McVinish, who staged a splendid lot; Mr. Ward was a good second, Mr. Shaw was a close third, and Mr. Read a capital fourth. For Messrs. Sutton & Sons' prizes for six dishes four collections were staged, Mr. T. Smith was first followed closely by Mr. McVinish. For Messrs. Webb & Sons' prizes for the same number of dishes three collections were staged; Mr. Evans was placed first, Mr. Lovett second, and Mr. G. Hampshire third. For a collection of Potatoes Mr. Salisbury was first with about thirty splendid dishes. Mr. Shaw staged fifty-one dishes, and was placed second, having several inferior dishes in the collection. Mr. Smith was placed third. Four collections were staged.

The Committee deserve congratulation. We hope, in future, some of the newer methods adopted for staging and the writing of the prize cards will be carried out, which will save time, labour, and confusion on the day of exhibition.

ROYAL CALEDONIAN.—SEPTEMBER 7TH AND 8TH.

NOTWITHSTANDING what has been universally conceded to be a bad season, the tables occupying the floor of the Waverley Market appeared as well furnished as usual on the occasion of the autumnal fruit Show held in Edinburgh last week. True, many of these were, in the words of Squire Hildebrand's unctuous gardener, Andrew Fairservice,

"decorated" by the trade; but to the tribes who go up to Athena Nova when the autumnal equinoxes have arrived that is not a matter of lamentation, for to the out-of-the-way country gardener the big show too often is the one and only means of seeing and choosing the novelties of the hour. For all such, a numerous band of nurserymen and florists of repute had a varied, interesting, and in most cases a most beautiful display. But of these more anon.

Turning our attention first of all to the tables of competition produce it was found, as is always the case, that fruit, and especially the fruit of the Vine, was the feature of the Exhibition. Most unfortunately for many of the exhibitors numbers of splendid examples of high-class culture were necessarily placed in a low position on account of want of finish, white Muscats in most cases being far from ripe, and in not a few instances black sorts were in the like condition.

Collections of Fruit.—With twelve dishes there were five competitors, the first prize being won by Mr. McKelvie, Broxmouth Park, Dunbar, with a collection in which Grapes were decidedly the chief feature. The clusters were not of large size, but perfectly ripened, and of beautiful colour and finish. The varieties were Alicante, Gros Guillaume, and Muscat of Alexandria. The other dishes comprised good Barrington and Bellegarde Peaches, Nectarines, good Figs, Melon, Clapp's Favourite Pear, Apples, Apricots, and good Jefferson Plums. The second place was accorded to the collection set up by Mr. Boyd, Callander House, Falkirk, who also had fine Grapes, the Alicante and Madresfield Court being very fine,

FIG. 34.—SOPHRO-CATLEYA VEITCHI. (See page 240.)

with two clusters of good Black Hamburgs. Peaches were among the best of the other dishes. Mr. Hunter, Lambton Castle, Durham, secured the third prize, the Apples and Pears being particularly fine in this collection. For eight dishes of fruit Mr. McKelvie again secured the premier award with fine Alnwick Seedling and extra fine Muscat of Alexandria Grapes, a good Smooth Cayenne Pine Apple, Peaches, fine Humboldt Nectarines, Melon, Figs, and Apricots. The second and third places were taken respectively by Mr. Smith, Oxenford Castle, and Mr. McIntyre, The Glen, Peebles, good collections being set up by each exhibitor.

For a collection of orchard house fruit Mr. Hunter was the only exhibitor, and had first prize awarded for an extra fine display, Pitmaston Duchess and Souvenir du Congrès Pears and Cox's Pomona and Golden Winter Pearmain Apples being the best dishes. For a collection of hardy fruit the prizes were secured by Mr. Dow, Newbyth, Prestonkirk; Mr. Day, Galloway House, Dumfries; and Mr. John McIntyre, Darlington.

Grapes.—Six lots of six bunches in three sorts were staged for the handsome prizes offered in this class. The splendid examples of Black Alicante, Madresfield Court, and Black Hamburg staged by Mr. Boyd secured for him the premier award; Mr. Murray, Park Hall, Polmont, coming in a very good second with extra Cooper's Black, Alicante, Madresfield Court, and a good Muscat of Alexandria. Mr. Kirk, Norwood House, Alloa, was third with good bunches. With four bunches, distinct varieties, Mr. Leslie, Pitcullen House, Perth, was first, the sorts being Black Hamburg, Alicante, Muscat of Alexandria, and good Gros Maroc. Second, Mr. Murray, Polmont; and equal third, Mr. Kirk and Mr. Green, Yester, Haddington. For two Muscat of Alexandria Mr. McKelvie secured the first place with medium thoroughly ripened clusters. Second, Mr. J. Mattison, Currie, with large bunches; and third, Mr. Day. Mr. Murray, Polmont, was first with two very fine examples of Black Hamburg in a very largely filled class of extra good Grapes

Mr. McKinnon, Melville Castle, Lasswade, was second; and Mr. Boyd third. In the one bunch class Mr. Kirk had the finest Black Hamburg; Mr. Caldwell, Langholm, Muscat of Alexandria. Mr. Green the finest Alicante in a good class. Mr. Boyd second. The latter was first for extra Lady Downe's; Mr. Murray, Culzean Castle, for Alnwick Seedling; Mr. Kirk for Gros Colman; and Mr. Day for fine Gros Maroc in the class for any other black sort than those named. Mr. Murray was first with Foster's Seedling for any other kind of white.

Other Fruits.—Mr. McKelvie, in a small class, had the best Smooth Cayenne Pine Apple; Mr. McIntyre, The Glen, was first for two Pine Apples, Mr. McKelvie second, and Mr. Boyd third. The best Figs were staged by Mr. D. Murray, and the finest twelve Peaches and also twelve Nectarines by Mr. Lunt, Ardgowan. Both of these were notable dishes in very largely filled classes. The best six varieties of dessert Plums were those of Mr. Bowman, Lasswade, and the best kitchen sorts those of Mr. Day. There were also single dishes of these. Of Apples and of Pears there were very large quantities, but nearly all were green and very few anything like ripe. The best collection of Apples in twelve varieties was that of Mr. D. Murray, who also had the best collection of Pears. In the class for single dishes of Apples were some good Ecklinville Seedling and Lord Suffield. Good single dishes of Strawberries, Cherries, Gooseberries, and Currants in variety were staged in large numbers.

Plants.—One of the best features in the Exhibition was the arrangement of plants with which Mr. John McIntyre of Darlington secured the first prize for a table of plants 20 feet by 5 feet. This was very well done indeed, while the plants were varied and well grown. The second prize was secured by Mr. Wood, Oswald House, Edinburgh. The specimen flowering and foliage plants were not in large numbers, and were of medium size. Mr. McIntyre was first for six flowering stove or greenhouse plants, Mr. Geo. Wood having the corresponding position for three. Mr. McIntyre was also first for four foliage plants and for Dracenas and Crotons. Orchids were only a small exhibit, Mr. Sharp, Forgandenny, being first for four and one, and Mr. Currie, Eskbank, first for two species. Ferns were of fair size and beautifully fresh, Mr. James Napier, Murrayfield, securing the chief prizes—*e.g.*, for six exotic, three exotic, four Adiantums, three Filmies, and six British Ferns. There was also a fair display of Fuchsias, Tuberous Begonias, Chrysanthemums, Lilliums, Zonal Pelargoniums, Cockscombs, &c.

Vegetables.—These were very plentifully represented, several collections of twelve sorts being set up in most excellent condition. In this class Mr. Low was first, and had, among other seasonable sorts good Tomatoes, Cucumbers, Cauliflowers, Onions, Leeks, and Celery. Mr. W. Harper was a good second, and Mr. Rae, Sunlaws, Kelso, third. In the single dishes Mr. Sime, Prestonkirk, was first in a good competition with twelve extra fine Tomatoes. Mr. Wilkins, Hensbridge, Blandford, and Mr. Bowerman, Hackwood Park, Hants, with Onions, were respectively first and second for these useful esculent with enormous bulbs. Mr. P. Robertson, Jedburgh, had first place for twelve sorts of Potatoes, and Mr. J. Riddell, Chapelton the first prize in the corresponding class for six sorts.

Cut Flowers.—These were rather sparsely represented. The feature among them was undoubtedly the stand of thirty-six lovely Roses with which Messrs. Cocker & Sons, of Aberdeen, secured the first prize; every bloom was in perfect condition, and was characterised by extreme freshness. Messrs. D. & W. Croll, Dundee, were a good second. Good Carnations and Picotees were staged in both the nurserymen's and gardeners' section; in the former Mr. M. Campbell, Blantyre, taking the first prize, and in the latter Mr. R. Cossar, Musselburgh. Messrs. Stuart & Mein, Kelso, were first for thirty Gladioli, good spikes of Formosa, Aurore de Feu, Opale, Bicolore, Pasteur, Enchanteresse, Horace Vernet, and Dr. Bailly being prominent. Mr. Whitelaw, Brechin, had the best twelve spikes. Messrs. Kerr & Sons, Kalemouth, staged some fine Hollyhock spikes, securing first prize for these. Dahlias in the several classes were well represented, Mr. Campbell being a good first for twenty-four blooms, Show, Messrs. Cocker & Sons first for eighteen and twelve Show sorts, and Mr. H. Dickson, Belfast, first for twelve Fancies. Mr. M. Forrest, Mr. J. Aitken, and Mr. Pearson were the chief prize-winners in the smaller classes devoted to gardeners. Good Pansies, Chrysanthemums, stove and greenhouse plants, and Orchid blooms were also staged.

Miscellaneous Exhibits.—As already indicated, these formed a very interesting addition to the competitive produce. In one corner Messrs. Cocker of Aberdeen had a most attractive display of cut hardy herbaceous, and other flowers, and round these a constantly changing group of notetakers congregated. Next to it a more modest if not less interesting exhibit was equally attractive and as difficult of access. This comprised a collection of thirty-six sorts of the newest and best of Mr. Eckford's Sweet Peas, presided over by the genius who evolved them. In close proximity to these Mr. T. S. Ware, Hale Farm, Tottenham, had a group of well-grown double Begonias of the best sorts, with a few singles intermixed. Close to these, again, a selection of many kinds of florists' flowers from Mr. J. Forbes, Buccleuch Nurseries, Hawick, filled a large table. In another part of the building Carnations set up among Maidenhair Ferns were a speciality which Messrs. Laing & Mather of Kelso, illustrated with examples of such popular sorts as Mrs. Muir, Germania, Duchess of Fife, and others. Messrs. Storie & Storie, Dundee, had a group of plants with cut flowers of Carnations, and so on.

In another corner Mr. D. W. Thomson had a semicircular group arranged on the floor and consisting of a varied collection of stove and greenhouse decorative plants. Messrs. Birkenhead had a table of their

Ferns from Sale, while Messrs. Methven, of Edinburgh, had on one table a mass of Begonias and on another a group of excellent plants for effect. Messrs. Dicksons, Waterloo Place, among a number of plants of the same character had many examples of cut flowers and Apples from their fruit nursery at Liberton, Midlothian. Messrs. R. B. Laws and Sons produced a light and effective arrangement of foliage and flowering plants, and Mr. Glass, Florist, George Street, another composed of the plants employed in the floral decoration business.

At one end of the building a honey show with bees at work, and illustrations of subjects connected with apiculture, formed the centre of much attention.

INTERNATIONAL HORTICULTURAL EXHIBITION.

SEPTEMBER 9TH AND 10TH.

THE list of special fixtures at the International Horticultural Exhibition was continued with a show of autumn flowers on Friday and Saturday of last week. As usual, an extensive display was got together, largely composed, as was to be expected, of Dahlias, Gladioli, and miscellaneous hardy flowers. The class for a collection of the former arranged for effect, similar to that at the Crystal Palace a year or two ago, proved to be a great success, and was undoubtedly the most attractive portion of the Exhibition, the competing displays forming a grand floral spectacle along one side of a large annexe. Gladioli were of splendid quality, but there was nothing noteworthy amongst the Chrysanthemums. The different non-competing exhibits referred to at the end of the report contributed greatly to the beauty of the Exhibition.

The collections of stove and greenhouse flowers in bunches, not less than twelve varieties, were extremely beautiful. Mr. A. Gibson, gardener to T. Burnaby Atkins, Esq., Sevenoaks, won with delightful clusters of bloom, but they would have been all the better if they had been arranged a little more loosely. He had *Pancratium fragrans*, *Dipladenia Brearleyana*, *D. insignis*, *D. amabilis*, *D. boliviensis*, *Allamanda magnifica*, *A. Hendersoni*, *Ixora Dixiana*, *I. Fraseri*, *I. Williamsi*, *I. Prince of Orange*, *Eucharis amazonica*, *Lapageria rosea*, *L. alba*, *Bougainvillea glabra*, *Clerodendron fallax*, *C. Balfourianum*, *Statice profusa*, *Anthurium Schertzerianum*, *Stephanotis floribunda*, *Rondeletia speciosa*, seedling *Gloxinias*, *Plumbago capensis*, white *Petunias*, and *Franciscea calycina major*. Mr. J. Prewett, Hammersmith, was second with a charming collection; although the material was hardly so good as in the other stand the flowers were better displayed. An extra prize was awarded to Mr. J. T. Hoare, Twickenham.

Gladioli in collections formed a magnificent display. Messrs. Burrell and Co. had an exhibit as remarkable for the quality of the spikes as for its extent, and were deservedly placed first. Some of the varieties were superb, and although too numerous for all to be named, *Dalila*, *Grand Rouge*, *Pasteur*, *Flambeau*, *Baroness Burdett Coutts*, *Cygnets*, *Carnation*, *Abricote*, *Florence*, *Amitié*, *Crêpuscule*, *Gladys*, *Irene*, *Mr. Fowler*, *Mrs. Peter Blair*, *John Wills*, and *Hetty Dean* may be noted as particularly beautiful. There were also many fine seedlings. Messrs. Harkness and Sons, Bedale, had a smaller but very fine collection. Some of their spikes were quite remarkable, notably *Baroness Burdett Coutts*, *Enchanteresse*, and *Dalila*, while others were excellent. They received the second prize. Mr. E. B. Lindsell, Bearton, Hitchin, who bids fair to grow Gladioli equally as well as Roses, was the only exhibitor in the amateurs' class, but he had a very good collection, and merited the first prize which was awarded. But why not have named the varieties?

Dahlias were freely shown, and added largely to the attractiveness of the Exhibition. Four competed with sixty Show and Fancy varieties, Messrs. Keynes, Williams & Co., Salisbury, following up their brilliant successes at the Crystal Palace and Royal Aquarium by scoring another highly meritorious victory. As at other exhibitions, their flowers were more noteworthy for freshness, build, and colour than great size. The present must be ranked as a year of somewhat small flowers. The best blooms in the first prize stand were *Alice Emily*, a sport from T. W. Girdlestone; *Buttercup*, *Peacock*, *Harry Keith*, *John Hickling*, a sport from Rebecca (dark self), and *William Rawlings*. Mr. Chas. Turner, Slough, followed somewhat closely, but on the whole his flowers were somewhat smaller than those in the first prize stand. In freshness and colour they were unexceptionable. Perhaps *John Standish*, *Maud Fellowes*, *T. W. Girdlestone*, *Harry Keith*, *John Bennett*, and *Constancy* were the best blooms. Mr. G. Humphries, Chippenham, was third. There was a very close struggle with twenty-four blooms, and it was only after a very careful scrutiny that the award was given in favour of Mr. Mortimer, Farnham. He had an excellent stand, the flowers being noteworthy for freshness and fine colour; *Burgundy*, *Jas. Cocker*, *John Hickling*, *Clara*, and *Mrs. David Saunders* were very fine examples. Mr. J. Walker, Thame, was second with a very even and good stand, the best blooms being *Harry Keith*, *Jas. Cocker*, *Majestic*, and *R. T. Rawlings*. Messrs. Saltmarsh & Son, Chelmsford, were third with smaller but fresh neat flowers. Messrs. Harkness & Son had very large albeit somewhat coarse flowers, and were awarded fourth prize.

The amateurs showed well also. Mr. Thos. Hobbs, Easton, Bristol, fairly defeated Mr. J. T. West, gardener to W. Keith, Esq., Cornwalls, Brentwood, in the class for twenty-four, having decidedly heavier blooms. Both were good stands, although the flowers ran rather small. Mr. Hobbs showed *John Hickling*, *Mr. Glasscock*, *Hope*, *A. Ocock*, and *Dorothy well*, while Mr. West's best flowers were *Queen of the Belgians*, *Maud Fellowes*, and *Ethel Britton*. Mr. A. Ocock, gardener to Mrs. McIntosh, Havering Park, Romford, was third; and Mr. Sidney Cooper, Chippenham, fourth. The last named was first with twelve, having a

beautiful stand, the other prizes going to Messrs. West, Vagg, gardener to J. Theobald, Esq., M.P., and Hobbs.

A splendid feature was introduced through the inclusion of a class for a collection of Dahlias (any types) arranged for effect. This brought out abundance of beautiful material, and the effect produced by the various unconventional methods of arranging it was very fine. Messrs. Keynes, Williams & Co. received the premier award, their group being composed of a large columnar centrepiece furnished with Cactus varieties set in moss, two small end columns, and six shields chiefly furnished with Pompons. In front were stands of Show, Fancy, and Cactus varieties. There was quality of bloom as well as tasteful arrangement to be noticed. The second prize went to Messrs. J. Cheal and Sons, whose arrangement was essentially different. It consisted of a central sloping bank surmounted by a large basket and two small end banks, between these being bunches of Pompons, and towards the front boxes of Show and Fancy blooms, with Cactus and single varieties dotted about on a groundwork of Fern. Mr. T. S. Ware, Tottenham, was third, with a somewhat similar arrangement, but no boxes were introduced. All were beautiful displays.

Cactus Dahlias, eighteen varieties, in bunches of six, were best shown by Mr. C. Turner, who had a splendid stand, in which Sir Hugo, Panthea, Beauty of Arundel, Honoria, and Blushing Bride were very fine. Messrs. Keynes, Williams & Co. were a very close second with Bertha Mawley, Kynerith, Kaiserin, and Countess of Pembroke, extremely beautiful. Messrs. J. Cheal & Son were third. Mr. Turner won again with twenty-four varieties of Pompons, a model stand, the flowers being very fresh, neat, and refined. Messrs. Keynes, Williams & Co. were second, and Mr. M. V. Seale, Sevenoaks, third, both showing creditably.

There were two classes for Asters, and these flowers were charmingly shown. Messrs. Saltmarsh & Son were first, Mr. Sidney Cooper second, and Mr. J. Walker third with quilled flowers, while in the class for French Mr. Walker was first, Messrs. Saltmarsh & Son second, and Mr. Cooper third.

Chrysanthemums were not a very prominent feature of the Show. There were two groups of plants, and the awards were the same as at the Aquarium—namely, Mr. Vince, Highgate, first; and Mr. N. Davis, second. A second prize was awarded to Mr. Peter Blair for cut blooms. Mr. G. H. Sage received the first prize for Sunflowers, Messrs. Burrell and Co. the second, and Messrs. Paul & Son, Cheshunt, the third. Mr. Sage received a second prize for Michaelmas Daisies. Mr. J. R. Chard won for a funeral design, having a beautiful white anchor; Miss Baines was second, and Mr. Larke third. Mr. Chard was also first for a hand bouquet and for a vase of flowers and foliage, other prizes going to Mrs. Seale, Miss Baines, and Mr. Hudson.

Plums were well shown by private growers. Mr. W. Carr, gardener to Mrs. Clarke, Croydon Lodge, won with three dishes of dessert varieties, having good dishes of Kirke's, Jefferson, and Bryanstone Gage. Mr. P. Blair, Trentham Gardens, was second; and Mr. McIndoe, gardener to Sir J. W. Pease, Bart., Hutton Hall, Guisborough, third. The last-named won with cooking varieties, having splendid dishes of Magnum Bonum and Monarch, with Pond's Seedling fair. Mr. Carr was second, and Mr. Sage, gardener to Earl Dysart, Ham House, Richmond, third. The nurserymen's classes did not fill. There appeared to be only one competitor with Apricots, Mr. McIndoe, and he received the first prize for good dishes of Moor Park, Large Early, and Peach.

The miscellaneous exhibits were numerous and varied. Messrs. Lane and Son, Berkhamsted, sent a collection of Vines in pots. They were trained on a bamboo framework 18 inches in diameter at the base and 3 feet at the top, and carried about ten neat bunches each, the varieties being Alicante, Buckland Sweetwater, Black Hamburgh, Foster's Seedling, and Gros Maroc. They also had branches of Plums, together with dishes of Apples, Plums, and Nuts, and received a silver-gilt medal. Messrs. Cheal & Sons, Crawley, contributed a stand of Dahlias, single, Cactus, and Pompon, hardy flowers and fruit (silver medal). Messrs. Reid & Bornemann, Sydenham, were represented by a handsome group of Chrysanthemums and other plants similar to that arranged by them at the Crystal Palace (silver medal). Messrs. J. Laing & Son, Forest Hill, had a large bank of herbaceous flowers comprising a considerable diversity of good material admirably set up, also double Tuberous Begonias, Roses, and Apples, with a few orchard-house trees (silver-gilt medal). Messrs. Chas. Lee & Son, Hammersmith, had a large and interesting bank of hardy foliage plants, also a beautiful collection of herbaceous plants and Dahlias. They had excellent material admirably arranged. It is a pity the foliage plants were not clearly named; they would have proved instructive to many. A silver-gilt medal was awarded. Messrs. Jarman & Co., Chard, had a bank of Dahlias, Phloxes, Gladioli, and other flowers set up in moss and interspersed with Ferns. It was very attractive (silver medal). Mr. H. Wrede, Lüneberg, Germany, sent a collection of Pansy blooms (silver medal). Mr. Chas. Turner had some fine stands of Dahlias (silver medal), as had Mr. G. Humphries (bronze medal).

Messrs. B. S. Williams & Son, Upper Holloway, were represented by a large and handsome group of Crotons, Dracænas, and other foliage plants—clean, healthy, and well coloured (silver-gilt medal). Mr. C. Williams showed shell table decorations. Messrs. Cannell & Sons, Swanley, had a beautiful collection of Cactus and Pompon Dahlias. They were arranged in bunches with Asparagus, and rose above a cool groundwork of Fern, which brought the colours out splendidly. Juarezzi, Ernest Cannell, Beauty of Arundel, Robert Cannell, Yellow A. W. Tait, Sir Roger, and Cannell's Favourite were very noteworthy. They also had a stand of double Begonias (silver-gilt medal). Mr. E. F. Such,

Maidenhead, sent a bright collection of hardy flowers, Dahlias, and Roses (silver medal). Messrs. E. D. Shuttleworth & Co., Peckham Rye, contributed a splendid bank of Palms, foliage plants, and large groups of Lilioms, occupying the whole of one end of the largest annexe. A fine plant of *Blechnum splendens* was noticeable, also two good specimens of *Rhaphis humilis* (gold medal). Messrs. Wills & Segar also had some huge Palms. Messrs. Cutbush & Son, Highgate, had a bright and varied display of hardy flowers, but they had hardly enough room at their disposal for arranging them effectively (silver medal). Mr. G. Garner, gardener to Mrs. Braddyll, Amberwood, Christchurch, contributed a collection of fruit, which included some splendid clusters of Alnwick Seedling and Madresfield Court Grapes (silver medal). Mr. McIndoe, gardener to Sir J. W. Pease, Hutton Hall, Guisborough, sent four splendid dishes of Peaches. Golden Eagle and Exquisite were superb (bronze medal). Mr. R. Nicholas, South Molton, exhibited a very fine collection of Pine Apples (silver medal).

Mr. A. Rawlings, Romford, had several stands of Show and Fancy Dahlias, comprising numerous excellent blooms (silver medal). Mr. J. Walker, Thame, also exhibited Dahlias. Mr. J. T. West, gardener to W. Keith, Esq., contributed some beautiful stands of Show, Fancy, Cactus, and Pompon Dahlias. He was awarded a silver medal, and another went to Mr. Mortimer for a similar exhibit. Messrs. Pitcher and Manda, Swanley, set up a charming group of hardy flowers, in which there were several interesting things (silver medal). Mr. Carr had some good Peaches and Nectarines.

Messrs. Paul & Son, The Old Nurseries, Cheshunt, had a very large and beautiful display, comprising Roses, Dahlias, Phloxes, Michaelmas Daisies, Carnations, and numerous other flowers (silver-gilt medal). Mr. R. Dean, Ealing, received a bronze medal for a collection of French Beans. Mr. W. Salmon, a working West Norwood amateur, exhibited a good collection of Asters, Dahlias, Zinnias, and various other flowers, and well deserved the bronze medal awarded. Mr. W. Welsford, South Lambeth, received a bronze medal for a collection of flowers grown in a town garden. Mr. W. Wells, Earlswood, Red Hill, received a bronze medal for a collection of Chrysanthemums. Mr. Chard was awarded a silver medal for some beautiful table decorations, and Mr. Seale a bronze medal.

LEICESTER AND MIDLAND CHRYSANTHEMUM SOCIETY.—

FIRST ANNUAL SHOW OF EARLY FLOWERING CHRYSANTHEMUMS, DAHLIAS, AND ASTERS.—SEPTEMBER 10TH.

THE Committee of the above named Society determined this season to follow the example set by the National Chrysanthemum Society and initiate a Show as above. A suitable room was found for the purpose in the lecture hall of the Young Men's Christian Association, a well lighted, centrally situated, and convenient room, which, when furnished, the tables with cut flowers, plants, and vegetables, and a portion of the floor space with groups of specimen plants and Ferns, had a very pleasing effect.

Chrysanthemums were not numerous shown, but there were some very meritorious exhibits both in plants and cut flowers. First to be noticed on entering the room was a group of fifteen bunches of early flowering Pompons exhibited by Mr. Robt. Owen, Castle Hill, Maidenhead, not for competition. In the open class competition Mr. W. K. Woodcock, Barkby Road Nurseries, Syston, was placed first in each of the two classes for six blooms of early flowering Chrysanthemums, distinct, and for six bunches, not more than six flowers in a bunch. Messrs. H. & J. Hickling were second for six blooms, and Mr. H. Jordan for six bunches. In the amateurs' class for six blooms Mr. H. Yeomans was first and Mr. H. Jordan second.

In the open class for twelve Show or Fancy Dahlias the exhibits were very fine and competition close. Messrs. Hickling were placed first, their varieties being James Cocker, Perfection, Colonist, Mrs. W. Slack, Mrs. Peter McKenzie, Majestic, Rev. J. B. M. Camm, Mrs. G. R. Jefford, Eclipse, Mrs. Langtry, Duke of Fife, and Peacock. The second prize stand was shown by Mr. James Wright, 49, Granby Street, Leicester. Adjoining these were thirty blooms of seedling Cactus Dahlias raised by Mr. J. Lansdell, Barkby Hall Gardens, Leicester. Two of these were singled out by the Judges for awards of merit; one especially is likely to come to the front as a popular and useful variety. The colour and marking are similar to W. T. Abernethy, but it is far superior to that well known variety in form. In the amateurs' class for six Show or Fancy Dahlias Mr. T. Faulkner, Myrtle Road, was first with neat, medium sized blooms, and Mr. E. Neale, Clarendon Park, second. For twelve Pompons Mr. H. Yeomans was first, Mr. E. Neale second. For six Pompons Mr. H. Yeomans was first and Mr. J. Bowles second. For six blooms of Cactus Dahlias Mr. H. Yeomans was first, Mr. E. Neale second, and Mr. T. Faulkner third. For twelve Asters grown by amateurs, first, Mr. H. Yeomans. Second, Mr. J. Bowles. Third, Mr. T. Faulkner. Extra prize, Mr. J. Bowles. These were all of high quality, being large, clean blooms, brightly coloured and so exceedingly close in order of merit that the Judges were a long time in making their awards.

For collections of vegetables Mr. E. Neale was first, Mr. H. Yeomans second, Mr. T. Faulkner third, and Mr. W. Henson, Flax Road, fourth.

Exhibits not for competition comprised a fine collection of vegetables and bunches of annuals, cut flowers, by Messrs. Harrison & Sons, Royal Midland Seed Stores, Leicester; a fine group of Chrysanthemums and Ferns by Mr. J. Smith, gardener to S. Bennet, Esq., Holmfirth, Leicester;

a group of early flowering Chrysanthemums, Asters, and foliage plants by Mr. W. K. Woodcock; a group of large specimen Zonal Pelargoniums and Coleus by Mr. H. Rogers, Gipsy Lane Nurseries, Leicester; a group of Palms, foliage plants, cut Delphiniums, Phloxes, and a tray of vegetables by Mr. H. Bell, the Hon. Sec.; Dahlias by Mr. G. Perkins, Birstall Lane Nurseries, and Mr. Jas. Wright, Granby Street; also a fine box of Comet Asters by Mr. H. Rogers.

The Show was formally opened at 2 P.M. by Mr. Alderman Kempson in the unavoidable absence of the Mayor, who had undertaken the duty. During the afternoon papers were read on the "History and Culture of the Dahlia" by Mr. W. Bell, F.R.H.S., and on the "Early Flowering Chrysanthemum" by Mr. W. K. Woodcock, F.R.H.S. Chairman, Mr. Councillor Collins.

HARDY FRUIT GARDEN.

Preparing Ground for Planting.—The importance of making a good start when fruit culture is contemplated ought to be impressed on everyone at the present time of the year. The actual work of planting fruit trees is not laborious when every preparatory detail has been carefully worked out beforehand at the proper time. The first object for careful consideration is the selection of a proper site. Most fruit trees like a sunny, open, breezy position, and if such a site can be secured with adequate shelter from strong winds, they will succeed, provided the soil is suitable.

Draining Soil.—If situated where the natural drainage is defective the land will not grow satisfactory fruit, except perhaps Black Currants; and, therefore, after the selection of a site, the proper draining of the soil is the next important matter to be dealt with in the preliminary preparations. If a sure test of its condition is needed, dig a hole 3 feet deep in some part of the land selected, allowing it to remain open for some time. If, in the course of a short period water collects in the hole from the surrounding subsoil, then draining will be absolutely necessary, but if little or none finds its way there the artificial draining will not be needed.

Deep Cultivation and Manuring.—Trenching is of great advantage to the generality of soils if performed in the right manner. This consists of not bringing to the surface a large bulk of inert hungry subsoil and disposing the better surface soil below, but rather in moving it to the depth of 2 feet without materially altering the position of the surface, which is generally considered to be the best. If very poor indeed it may be desirable to add well decayed manure during the process of trenching, but ordinarily fertile soil that will grow good vegetables will also grow good fruit without adding manure during digging operations, and too much of this forces rank, sappy growth. Manure is best applied to fruit trees from the surface.

Soil.—The most generally useful soil for fruit trees is a strong loam, slightly approaching to marl or clay. Stone fruit trees require it more of a calcareous nature, or made so by the addition of lime. A somewhat firm soil being an essential in fruit culture early preparation affords time for a deeply moved plot of ground to become consolidated by the time the planting period arrives. Land laying rather low, not absolutely waterlogged, yet sufficiently damp to militate against satisfactory results being attained, may be improved by being laid up in wide ridges, so as to raise it above the original level. In damp situations stations are also formed in a similar manner for each tree, 6 or 8 feet in diameter usually proving sufficient. The advantage of early preparation of the ground affords the opportunity of doing the work well, when the weather is finer and the soil drier than is sometimes the case in late autumn. It also gives the planter the means of selecting the time for placing in the trees at an earlier period when the weather is favourable for the work. Hurried preparation of the ground and hasty planting in probably damp weather, when the soil impedes the free use of the tools and attaches itself to the boots, is never satisfactory. It is even more important that the borders in front of walls intended for fruit trees should be prepared early, because of the sinking of the ground which follows deep stirring.

Lifting and Root-pruning.—Irregularity in crops of fruit is often followed by superabundant growth, and consequently further unfruitfulness. This can often be remedied by careful lifting and replanting, or if not root-pruning is often a remedy and always a check to strong growth. The present is a very favourable time to note the trees, observing the tendencies they have in the way of wood growth. Restricted trees disposed to make much secondary growth after being duly stopped since the summer pruning or pushing strong growths from latent buds in various parts of the trees would be benefited by lifting and replanting if small in size, and by root-pruning if of large proportions. The operation, however, need not, in fact should not, be done at present, unless very carefully or only partially operated upon.

Strawberries.—The season being favourable for the abundant rooting of Strawberry runners, which have been left between the plants, these, if carefully lifted and planted now on good ground, will grow vigorously, and almost certainly produce a good crop of fruit next year.

The ground between earlier planted runners may be kept freely hoed in intervals of dry weather to destroy seedling weeds. In many cases Strawberry beds containing established plants are much neglected from the time the fruit is gathered until late in autumn, when a wholesale clearance of runners and weeds is effected. This is a great disadvantage, because the main crowns are deprived of support as well as light and air by the rank growth of runners. All such should be cleared away forthwith, so that the crowns of the main stools may become plump and strong before growth ceases. By this means severe winters have less effect upon the plants, and they start strongly again in the spring, although the old foliage may have been severely crippled by the winter's frosts.

FRUIT FORCING.

Vines.—*Young Vines.*—These should have every encouragement essential to the perfecting of their growths, keeping the foliage clean, removing all laterals, as growth produced after this time is of no value, and maintain a warm well ventilated atmosphere until the canes are thoroughly ripened. Any supernumeraries intended to fruit heavily next season should have the laterals cut away to the principal buds, leaving, however, an outlet for any excess of sap by a few joints of the laterals beyond the length of cane to which they are to be shortened, and be careful not to injure the principal leaves. If the wood does not ripen well it may be accelerated by keeping the house rather close in the daytime, so as to get a temperature of 85° to 90° from sun heat, opening the ventilators at night. Afford sufficient water at the roots to prevent the foliage becoming limp.

Midseason Houses.—When the Grapes have been cleared from the Vines divest the shoots of their laterals down to the principal buds which are to be retained for next year's fruiting, but be careful to avoid injuring the old leaves, for upon their preservation in health depends the maturation and plumping of the buds, also the storing of food in the adjacent wood, as well as the ripening of the wood, which is essential to a good break and a proper development of the bunches in their early stages next season. Allow a free circulation of air, and in the case of young or luxuriant Vines, or where there is the least doubt about the thorough maturity of the wood, maintain a gentle warmth in the hot-water pipes. After the removal of the laterals clear off the remains of mulchings or remove the loose surface soil, particularly near the collar of the Vines, picking the old soil from amongst the roots, and supply fresh lumpy loam in its place. Avoid burying the roots deeply, a couple of inches is deep enough. They will push adventitious roots into the new material, and these can be encouraged to any extent by timely surface dressings or light mulchings when the Vines are in need of support another season. If a handful of steamed bonemeal is sprinkled on each square yard of border, and double the quantity near the stems, it will aid the Vines wonderfully in the early stages of growth another year. Inside borders will need watering so as to keep the soil healthfully moist. Outside borders should have the benefit of October rains, and may be covered with 3 or 4 inches of dry leaves in November, with a little litter over them. In the case of borders that are only partly made a breadth of about 2 feet may be added to the front, choosing dry weather for the operation, and compressing the materials moderately. If inside afford a good watering, if outside it will not be necessary unless the compost is dry; cover up in due time as before advised.

Late Muscats.—These require fire heat until they are thoroughly ripe, with a free circulation of air in the daytime, and enough at night, with gentle warmth in the pipes, to insure a circulation of air and to prevent the deposition of moisture on the berries, being careful to admit air rather freely on fine mornings. Continue this until the Grapes are thoroughly finished, when a gradual reduction of temperature may be made to about 50° at night, but there must not be any hurry in this, as the Grapes put on colour long after they appear finished, and improve in quality so long as there are any leaves on the Vines. Keep the border moist by watering as necessary in the early part of a fine day, for though the leaves become yellow at the edges they have green parts more or less that are useful in assimilating and storing food. Moisture must be kept down by free ventilation; it is pent-up air with a sudden increase of temperature from sun in the early part of the day, or at any time, which causes moisture to condense on the berries and produce spot, when the berries speedily decay.

Late Grapes.—The thick-skinned Grapes are not so fastidious as regards moisture as the thin-skinned Muscats (Canon Hall and Muscat of Alexandria), for Mrs. Pince Muscat will shrivel in a house where there is sufficient moisture to cause Muscat of Alexandria to rot. They are also liable to give evidence of finish that will not bear close examination, therefore make sure that the berries are well finished quite up to the shank before ceasing the needful aid from fire heat. Mrs. Pince's is perhaps the worst to finish of all Grapes, and unless it is thoroughly ripened it is sure to shrivel. Alicante and Lady Downe's finish better and in less time than Gros Guillaume and Gros Colman, therefore the latter should be given more time; also the white varieties, Syrian and Trebbiano, and after they are apparently finished a temperature of 55° should be assured, with a rise of 5° to 10° by day and a circulation of air until the foliage is giving indications of falling, when a temperature of 50° is sufficient. The inside borders should be watered in the early part of a fine day and air be freely admitted, for it is not so much the moisture as its confinement that causes berries to crack. Outside borders will be quite damp enough, and should be covered later on with spare lights to throw off heavy rains.

Late Hamburgs.—Houses of these that were allowed to start

naturally will perhaps need a little fire heat to colour and finish the Grapes satisfactorily, as they will when it is hopeless to do anything more with the thick-skinned varieties. They should have a temperature of 60° to 65° at night and 70° to 75° in the daytime, with a circulation of air constantly and free ventilation when favourable. Water the inside border if necessary, and the Grapes are only partially advanced in ripening. Only restrict the laterals to prevent overcrowding, as a good spread of foliage over thin-skinned black Grapes is the best safeguard against the sun taking colour out of them when ripe. When the Grapes are ripe gradually reduce the temperature, maintaining it at about 50° by artificial means by day and 5° less at night, with a little air constantly.

Cucumbers.—*Autumn Fruiterers.*—These must have every attention as regards affording copious supplies of liquid manure, removing superfluous laterals so as to guard against an overcrowded condition of the growths, taking off surplus fruits, male flowers, and tendrils, avoiding overcropping, and not allowing the fruit to remain on the plants after it becomes fit for use. It will keep several days in a cool place with the neck end stood in a saucer of water. Secure a genial atmosphere by damping available surfaces other than the plants in the morning, afternoon, and evening, syringing the plants lightly early in the afternoon of fine days. Train and regulate the growths about twice a week, pinching the laterals or shoots one or two joints beyond the show of fruit, and retain no more foliage than can have full exposure to light. Supply water as required, that and liquid manure being of the same temperature as the house. To encourage growth earth up the roots as they show at the sides of the hillocks or ridges, only just covering up the roots each time of their showing, the soil having been placed in the house so as to become warmed through before use.

Winter Fruiterers.—If these have not been planted out no time should be lost in effecting it, or if the house is not ready shift the plants into large pots and keep them growing near the glass in a temperature of 70° at night and 75° by day, with an advance of 10° to 15° from sun heat. If fermenting material is used for bottom heat it should be in preparation by throwing it into a heap, damping and turning the heap over to induce fermentation and the dissipation of noxious gases before making up the beds. Bottom heat, however, is better supplied by hot-water pipes surrounded and covered with rubble or placed in a chamber under the bed.

Pits and Frames.—The temperature should be maintained at about 65° at night by renovating the linings as necessary and placing night coverings over the lights to prevent too great a reduction of the heat. Keep the foliage thin by removing bad leaves and exhausted growths, and close early in the afternoon so as to husband as much of the sun's heat as possible. Afford water only at the roots to keep the foliage from flagging, and sprinkle the plants overhead only on fine days and soon after noon.

PLANT HOUSES.

Camellias.—These will bear stronger insecticides without injury now than at any other period of their growth. If scale or other insects exist upon them they should be thoroughly washed with a solution of petroleum and water at the rate of 1 oz. of the former to each gallon of the latter. Every portion of the tree should be well soaked and the trees shaded from bright sunshine for two or three days afterwards. If any traces of insects are left the application should be repeated in about a fortnight. After the trees are thoroughly cleaned expose them to full light and sunshine to harden and ripen their wood. This is necessary if the flower buds are to remain on and develop satisfactorily at the proper time. Abundance of air should be given both day and night, and the syringe should be used freely. Keep the plants moist, and if confined at their roots, or growing in poor soil, weak stimulants should be given every time they need water. When the flower buds are swelling the plants are rooting freely and need feeding more than is necessary during any other period of their growth. Occasional doses of soot water in a clear state are very beneficial and impart a fine dark hue to the foliage.

Azaleas.—Plants that are to flower early and have been standing outside should be housed at once. Before doing so, however, clean the house in which they are to be arranged thoroughly. If any thrips exist upon the plants they should be well washed over a tank with a solution of tobacco water, using 1 oz. of softsoap to four gallons, and adding a piece of common washing soda the size of a cob nut. The old stock, in whatever stage of growth the plants may be, should also be washed if infested with insects. Every effort should be made to stamp out thrips at this season of the year; if any are left upon the plants they increase rapidly after they are introduced into the forcing house. Those plants that have not been repotted may have their last application of Standen's or other favourite manure applied to the surface of the soil. When the plants are housed, arrange them, if possible, on a moisture-holding base, do not allow the plants to become dry, and syringe them freely. Any plants that are trained and need tying should be attended to as opportunity offers, so that the foliage will have ample time to turn to the light before the approach of winter. It is a mistake to leave this operation until the dark short days arrive.

Greenhouse Rhododendrons.—These useful plants are very subject to thrips, and if any exist upon them the insects should be eradicated at once, or the bold fine foliage will soon be destroyed. The solution advised for Azaleas will do very well. Where the plants have been grown fully exposed to the sun their wood will be firm, and the flower buds swelling rapidly. Keep the plants moist at the roots and syringe them freely. This treatment will not induce them to start into growth again after the flower buds have formed. One of the most

useful of this class is Princess Royal, which will yield its choice pink flowers over a period of six months.

Epacris.—Expose these to full sunshine, and protect them, if grown in frames, from heavy autumn rains. The lights should be thrown off whenever the weather is favourable. When the plants are housed stand them on ashes, give plenty of air, and syringe freely.

Heaths.—Softwooded kinds will be forming their flower buds, and on no account should they be allowed to become dry at their roots. If this takes place the flower buds may fail to come forward. Unless abundance of air is given *Erica autumnalis* is very liable to be attacked by mildew. During dull, damp weather watch for mildew on the different hardwooded varieties. At this season it need not be feared if abundance of air is given, except during spells of dull, damp weather. Those that have finished their growth may be tied and restaked if they need it, while those that are still growing must be left until later in the season.

Mignonette.—The last sowing should be made in 5-inch pots for spring flowering. Those sown some time ago and large enough should be liberally thinned. Too many plants should not be left in each pot, or they will grow weakly during the winter. Keep the blooms removed from those that are to flower when outside supplies fail. Do not allow the plants to become dry, and give them abundance of air.

Cyclamens.—These may still be repotted if they have not already been placed in the flowering size. If the plants to be repotted are throwing up flowers they should be removed. Sow seed in heat for next season's supply of plants. Late-sown plants established in thumbs may be placed into 3-inch pots. Grow the plants fully exposed to the sun. Give air liberally to insure sturdy growth.

THE BEE-KEEPER.

APIARIAN NOTES.

THE PUNIC BEE CONTROVERSY.

MR. T. W. COWAN threatens us with an action for libel because his name has appeared in articles on Punic bees, which bees he has publicly condemned both in this country and America. On requesting Mr. Cowan to specify the articles to which he objects, he refers us to "those from 'A Hallamshire Bee-keeper' and 'A Lanarkshire Bee-keeper' since the beginning of this year," so that, from his point of view, the whole of those articles are libellous. That is not our opinion, or they would not have been published. Both those writers have had experience with the so-called Punic bees. We have had no such experience, and have therefore neither condemned nor recommended them; and it is obviously requisite that the experience of persons should be published who have found the bees valuable or the reverse, with the grounds on which such experience is based, in order that the public may be able to form their conclusions on the subject. We have not suppressed any matter that has been sent to us in which these bees have been adversely referred to. Mr. Cowan thinks it right to condemn the bees, and to that we have not the slightest objection, but it surely follows that others who keep these bees have an equal right to defend them if they feel justified in doing so. We are ready to publish further experience on these bees, whether it is in their favour or not.

BEES AT THE HEATHER.

WE have reached the 9th of September, and for a month past one fine day is all our bees have had. For two days we have experienced a calm, the first time for several months. The Heather being late is still in good bloom; but sunshine is so rare, and the moisture in the earth and the atmosphere is so great, that with the low temperature little or no honey is secreted in the flowers. If fine weather would continue for a few days the bees might still, although out of season, gather a fair quantity of honey.

A BRIEF REVIEW OF THE SEASON.

The early spring was extremely ungenial. The first week in April was quite spring-like, but after that the weather was of an arctic character, being bitterly cold but dry. The first week in May was a slight improvement, giving promise of better times; but on the 7th of that month a change for the worse took place, and from then till now there have been only three genuine bee days for full working. Young queens hatched early in June did not show young bees till the 7th day of September.

The greatest flood in the memory of man fell on the evening and morning of the 28th and 29th of August respectively, and this was followed by a frost of 15° on the first mentioned day. On the 2nd of September snow and hail lay to a depth of 3 inches several miles above my bees, and on the following day the hills were white. My bees suffered little or no damage

from the flood, but a quarter of an inch more rain would have swept them off with the torrent. The stands were nearly a foot in water, all the moveable pieces were swept away, a wire fence close to them was forced out, coils of hay that stood more than a third of a mile distant were washed against them, and the mountain torrents blocked the roads in many places with heavy *débris*. I should like to ask our meteorologists to favour us with proper data on which the published decision is founded that this has been "the mildest season since 1876." I hope their instruments are not all kept near their bedrooms as some I know are. Scientific instruments should be isolated at least six miles from any town. I fail to see that there can be at thirty miles apart 10° difference of the temperature with accurate instruments; but we all want information. I do not expect to be much longer at the Heather, as we rarely see the sun.—A LANARKSHIRE BEE-KEEPER.

APICULTURAL ITEMS.

As an instance of how people may be led away by reading what has been said against me, I will give the following occurrence:—During the past season I sent Mr. John G. Kirsten, of Southborough, near Tunbridge Wells, eighteen virgin Punics, thirteen being all in one week. I supplied him with virgin queens in 1891 and 1890, so it may fairly be assumed that we ought to know each other. On August 7th he wrote to say that only five queens were laying, five more had left brood and disappeared, six more had neither queen nor brood, and two had gone, bees and queen, being a loss of thirteen queens out of eighteen. He described the transaction as "most unsatisfactory," and hoped I would "show by deeds" that I would bear out the contents of my statements and make good the loss, and much more in the same tone. Of course, I resented the tone of such a letter, and told him plainly and distinctly that it would be time to write such a letter when I had refused to make the loss good, as per my advertised guarantees, and not before; that I was ready to accept his word without question, that the five with brood and no queens would be found all right, and probably the six also, if he would test them. This he did, and then wrote me on August 11th saying, "To my great surprise you are quite right in what you said on the 8th of August. My loss really now amounts to four queens;" and then he asks the favour of letting them stand over to 1893. I enclose you, Sir, the two letters just to see the difference between them. [Received.—ED.] I mention this case, because it is an illustration of my twenty-five years' experience of average Britons. In my business dealings with them I find they are liable to make mistakes, but show them their error and they frankly admit it at once.

The other day I received a post card from Dr. C. C. Millar, Marengo, Ill., U.S.A., to say that two virgin Punics I sent him had arrived safely, only one worker being dead, were safely introduced, and were laying well, having duly mated. These two queens were seven days old when sent off, the package containing the two when ready to post was only 1½ oz. and it would be about twelve days on its journey. I mention this, because it is now four years since I claimed to have solved the problem of being able to introduce aged virgin queens safely, and thus open up a cheap and ready means of spreading "new blood;" also that I had solved the wintering problem, claiming that what is called "winter dysentery," was solely the result of breeding the queens in an imperfect manner. It was solely to demonstrate in a convincing manner that I began breeding and selling virgin queens, with what success all know who read this *Journal*, but in another quarter it has been insinuated that my queens are no better than others and that the winter problem still remains unsolved, in fact the greatest care is taken to prevent the public learning that what they had clamoured for as a most desirable thing for a generation, is at last within their reach. How far I have succeeded may be judged by the following: Up to the present no case of winter dysentery has been reported or claim made on my guarantee, and not more than six cases of unexplained failure to introduce the queens; there is not one failure of any kind reported this season, although the majority were novices, and none had ever introduced virgins. The losses have been in the mating, but this has been light, four from Kent and one from Ireland this season, so that my system of rearing and introducing virgin queens is an unqualified success and no longer theory. I have been able to make an equally valuable discovery in rearing and mating fertile queens, and next season I hope to let the public have the chance of benefiting by it.

Speaking from memory I have sent lots of queens to Lockerbie, but cannot say without referring. I do not think they would be pure Punics "A. L. B. K." mentions, but the result of a hybrid queen mating to pure Punic drone, being three-quarter Punic and quarter native.—A HALLAMSHIRE BEE-KEEPER.

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Pink Bedding Zonal Pelargonium (*J. L.*).—We do not remember seeing the variety you name; but if you write to Mr. Coppin, the Superintendent at Battersea Park, he may be able to give you some information. We have seen Mrs. Turner effectively employed in the parks, and Beckwith's Pink is highly recommended by Mr. Cannell.

Notching Vine Roots (*W. J.*).—If Vine roots are notched now, and a gritty compost, consisting of turfy loam and a large admixture of wood ashes, be placed round them they will form fresh roots this season; at least that is what we found in the case of some Vines that were improved by that process. Old Vines, such as you describe, and which cannot be lifted, usually bear better by training young rods very thinly in the summer, and not cutting them back closely at the winter's pruning.

The Keswick Codlin Apple (*Keswick*).—This useful Apple was not raised at Keswick, but was first discovered growing among a quantity of rubbish behind a wall at Glacston Castle, near Ulverstone, and was first brought into notice by one John Sander, a nurseryman at Keswick, who, having propagated it, sent it out under the name of Keswick Codlin. In the *Memoirs of the Caledonian Horticultural Society*, 1813, Sir John Sinclair, says:—"The Keswick Codlin tree has never failed to bear a crop since it was planted in the episcopal garden at Rose Castle, Carlisle, twenty years ago. It is an Apple of fine tartness and flavour, and may be used early in autumn. The tree is a very copious bearer, and the fruit is of good size, considerably larger than the Carlisle Codlin. It flourishes best in a strong soil."

Green Gage Plums Gummed (*S. C.*).—It is generally the result of a deficiency of calcareous matter in the soil, but not always, as we have seen it occur when there has been a very vigorous growth followed by a large reduction of foliage. We think, however, in your case that it is caused by a deficiency of calcareous matter. In the autumn we should give a dressing of quicklime at the rate of a bushel per rod (30½ square yards), and point it in with a fork as deeply as can be done without injury to the roots, mixing it with the top 9 inches or a foot of the soil. A better plan would be to get some old mortar rubbish, breaking it small, and picking out any pieces of lath or wood; and removing the soil down to the roots, picking some from amongst them and giving fresh to which has been added a sixth of the mortar rubbish. If the roots are deep they should be raised, bringing them up so that the topmost are not deeper than 3 or 4 inches when covered with soil, which also should contain the lime rubbish. Make the soil firm about the roots, and mulch the surface with short littery manure.

Orchids Spotted (*T. F.*).—The spot of which you complain is often brought about by the soil at the roots of the plants having become sour. It is also due to too much water at the roots of the plants and in the atmosphere. Nothing will cause the plants to become spotted sooner than a close saturated atmosphere. The temperature appears to have been high enough. A low temperature when the house is too moist would very soon bring about this state of things. We advise you to keep a drier atmosphere, and the plants slightly drier at their roots, also provide a circulation of air daily when the weather is genial; at the same time you must avoid cold draughts, for they are detrimental. If the soil is not sour at the roots, and you follow the directions given, the plants may be grown out of the spot another year. If the soil is sour repot the plants at once, remove carefully the old material and wash the roots in tepid water, then place them amongst fresh soil. Water must be applied with great care after potting until they commence growing and rooting in spring. When the air in the house holds the greatest possible amount of aqueous vapour in suspension, or, in other words, when it is fully charged with moisture, the two thermometers on the hygrometer will stand at the same level; but as the amount of moisture decreases the wet bulb thermometer will sink, and the greater the dryness of the atmosphere the greater will be the difference between the two thermometers. During the day, if the dry-bulb thermometer

stands at say 76°, the wet-bulb thermometer should be about 69°, and at night if the dry thermometer registers 70°, the wet one should be about 66°. These figures are given as examples, but they will be found to vary considerably with the different changes of temperature and seasons.

Forcing Choice Fruit, Flowers, and Tomatoes for Profit (Inquirer).—Many kinds of fruits, flowers, and vegetables are forced profitably by those having a thorough knowledge of the business, gained from experience in establishments where the produce is disposed of in the markets. Some persons, however, are very successful who have little cultural knowledge but good business aptitude, by engaging a competent working foreman, well skilled in the economy of labour and the production of goods that meet a ready sale and bring the best prices, by their excellence and the manner in which they are packed or presented. Then the capitalist has merely to superintend the strictly business side, and avoid speculations that are often disastrous. With a knowledge gained by paying a premium, as you suggest, you may or may not acquire sufficient insight to grow the crops determined upon so as to be fairly remunerative. We have not much faith in premiums, however, though they are sometimes useful, and in some cases essential, in gaining access to places where opportunities of becoming acquainted with special modes of culture are afforded. By all means acquire such knowledge by serving a time in not one only, but in two or three establishments, say a year or more in each, before commencing on your own account, and then we advise very thoughtful action, as profits are becoming less through increased and increasing home and foreign competition. If, after three years' experience in large establishments, you find you have sufficient aptitude and business capacity to engage with confidence in the undertaking, and can clearly see your way to make it fairly remunerative, we do not see why you should not succeed well with a capital of £1000. There is another expedient—namely, become a partner with a person who has everything but capital essential to enlarging a business and making it a success.

Pear Tree Leaves Blistered (Subscriber).—The leaves are severely infested with the Pear-leaf gall mite (*Phytoptus pyrinum*), which is invisible to the naked eye, and only just made visible by a good pocket lens. Under a powerful microscope the mite is a very interesting creature, with a long, slender, white body, two pairs of very short legs near the head, which is pale flesh in colour, and ends in a kind of conical projection containing the fine sword-shaped jaws, fitting on each other like scissor-blades, and with these and other very small mouth-apparatus the mite feeds on the tissues of the Pear leaves. The effect is that these leaves are very much injured, blistered spots resulting; these spots become brown or black, and are then very conspicuous, as in your case, by the depressed tufts, which were formerly believed to be caused by fungi (*Erineum*), but this has proved to be only hairs caused by the irritation of the mites. If the under side of the leaf is carefully examined a small hole will be found about the middle of each discoloured spot, giving passage to the mites to and from the interior of the leaf. By closely examining the blisters we found some excessively small white eggs with the mites emerging, also many shells of irregular shape from which the mites had hatched out. There were many dead mites in the blisters, and several alive near the blisters on the under side of the leaves; these mites are less than 1-200 inch in length and 1-800 inch in breadth at the widest part. They were very active for a few minutes, moving about on the green parts of the leaves, but soon died, evidently perishing in the endeavour to bore or cut into the green parts of the leaves, and so find the food they were deprived of in the blisters by the drying of the tissues. We advise syringing the trees infested with a sulphur solution made by slaking 3 lbs. of quicklime in an iron copper, adding 2 lbs. of flowers of sulphur and 3 gallons of water, besides that used in slaking the lime. Mix and boil for a quarter of an hour, keeping stirred all the time. Allow the mixture to settle, and when cool pour off the clear liquid, place in stone bottles, and keep well corked in a dark place. Use a pint of the bi-sulphide of calcium, as the liquor is called, to 4 gallons of water, applying with a syringe or garden engine, wetting every part of the leaves, particularly the under side. The application should be made without delay, and it may be repeated before the leaves are all down. Collect all the leaves as they fall and burn them, and when all are down remove the surface soil—the slightest skimming, with any leaves that remain, and burn it, supplying fresh soil in its place. As a preventive the trees may be syringed in spring, when the first leaves are about full-sized, with the following solution:—Dissolve 8 ozs. of softsoap in 4 gallons of boiling water, pour the soap solution on 1 lb. of sulphate of lime, keeping well stirred whilst the solution is slowly poured on, and when mixed and cooled to 90° apply to the trees so as to wet them in every part. Repeat early in June.

Names of Fruits.—*Notice.*—Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*G. M. Gerahty*).—Worcester Pearmain, one of the most handsome and useful autumn dessert Apples for market. (*T. D.*).—1, Kerry Pippin; 2, Grenadier; 3, Irish Peach; 4, Duchess of Oldenburg. (*J. J. C.*).—On a first glance we thought the Plum was the Red Magnum

Bonum, but on more closely examining the fruit we find the variety is a clingstone, and therefore conclude it is Pond's Seedling. (*W. M. B.*).—1, Bedfordshire Foundling; 2, Greenup's Pippin; 3, Herefordshire Beeding.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*W. W.*).—*Leycesteria formosa*. (*R. J.*).—1, Is a *Rudbeckia*, perhaps *laevigata*, but you do not mention the height; 2, *Agrostemma coronaria*; 3, *Sidalcea candida*; 4, *Achillea Ptarmica* fl. pl.; 5, *Episcia* (formerly *Cyrtodeira*) *fulgida*.

SHELTER.

AUTUMN comes on swiftly now, the nights are colder, with heavy dew, there is a suspicion of frost in the raw morning air, the valleys are shut in by mists which vanish slowly before the rising sun, and gusty winds sweep before them the sere and yellow leaves of the Elms, which this year began falling before

the end of August. These are some of the signs which tell us quite as plainly as bare stubbles do that autumn is at hand. There are others, too, of equal significance and of greater importance demanding heedful and prompt attention. A turn among the live stock after darkness has fallen shows us that however calm the night may be cattle and horses have gone to the warm side of any available hedge, tree clump, or building for shelter, and sheep are clustering upon some knoll or upon the hard dry surface of a drive. The sheep are lying down, but if the land is wet and cold the cattle and horses are standing about, thus plainly showing a want which we do well to supply.

That very much harm is done to live stock by a want of proper shelter in early autumn there can be no doubt. It is then that colds and rheumatism so frequently lay hold of valuable animals, hoose becomes rampant among calves, there is much coughing among sheep, fluke appears if the flock is kept on low damp ground, and horses and cattle fall off in condition—all of which tend to show the importance of preventive measures, of giving the provision of shelter that position in our practice which is so clearly to our advantage. Depend upon it not half enough attention is paid to the maintenance of health in animals of the farm. It is not a mere question of feeding. However nourishing may be the food it alone will not serve our purpose; shelter from wind and rain must always be accessible to the stock. A common mistake at this season of the year is the leaving of horses and cows out at night as long as they can bear it with apparent impunity. It is far better to turn them into yards with an ample provision of deep open lodges or hovels at night after the end of August. With full crops of second growth of Clover and of green Maize there is plenty of rack food for consumption in the yards, stress upon pastures is lessened, the animals are better for the mixed diet as well as for the shelter, and they are under much closer observation than is possible when they are left entirely in the open.

The sight of sleek, marsh f d beasts, just now at their best, may very naturally give rise to a question if after all yards and hovels are required so early in the season. Such beasts, be it remembered, have been summered on marsh or other good grazing land to come off ripe for the butcher in autumn. Even with them it is found dangerous to continue grazing late into October, many a fine beast being lost outright from exposure then on an open marsh devoid of hedges or shelter of any sort. They are withdrawn early; so, too, are marsh-bred lambs. Big sturdy animals as they are, they cannot bear the cold damp situation in winter, but are all driven to uplands, often a long distance off, till the following Ladyday.

Ewes folded now with the tups on Mustard or early Turnips have precisely the firm hard surface to lie down upon of which they are so fond, and the daily allowance of corn or cake which they have in the tup folds is conducive to high condition and health. November and December are regarded as dangerous months for them, because serious losses of ewes and abortion so frequently occur then, simply because they are folded upon Turnips, and are kept constantly standing in mud, often so deep that they move about in it with much difficulty. The cold watery diet lowers the temperature of the body to a serious—often fatal—degree, and the strain of walking in mud, out of which the legs are only withdrawn with much difficulty, is very trying. Clearly the ewes ought not to be exposed to it at any time, still less so when they are heavy with lamb.

It is probably owing to the inclement climate of Scotland that the provision of shelter at Scotch farms is so superior to that of many English farms. Yet one of the first requirements of North British farmers when they come south is for more buildings, which they evidently regard as indispensable for shelter apart from any question of mere temperature. They are right; and he is a wise landlord who affords his tenants an ample provision of means of shelter, both at the homestead

and out upon the different pasture enclosures. In dealing with this matter we treat every case upon the broad basis of general utility, paying very little heed to individual fancies. That is the only safe way to avoid annoyance and waste. Each farm must be treated upon its merits, and sufficient provision of shelter made for the head of stock it is calculated to carry, the buildings being so placed as to be accessible and convenient for use. Beyond this it is unwise to go, and we make a point of never asking a landlord to spend a penny more than is absolutely necessary. On the other hand, all possible pains must be taken to show cause for the due provision of enough shelter buildings, and to insist upon the point in the mutual interests of landlord and tenant.

Tenants are wont to ask too much, landlords to concede too little. It is for the agent to point out the happy mean which shall improve the value of the property for the one, and render the holding more useful for the other.

WORK ON THE HOME FARM.

Since writing our last note we have travelled some hundreds of miles through land set thick with corn in sheaves, but the weather was not at all favourable for carting it to the stacks, and September came in with very few cleared stubbles except along the south coast. During the first three days of the month the weather was very unsettled, yet the rain did no harm to Wheat in well built shocks, while it improved the Barley wonderfully, plumping the grain without staining it, for most of the straw is erect. With fine weather now much good work will be done, and the bulk of the corn in East Anglia and the midlands should be got together quickly.

We saw a field of Oats on a heavy land farm sadly mismanaged. The corn was foul with a thick strong growth of weeds. It was being reaped and tied up in sheaves with such a mass of weeds that severe heating in the stack and musty Oats were inevitable. In such a case the only safe plan was to mow into swathes and to turn and harvest like Clover hay. Even then, with fair weather, we should prefer threshing the Oats as they were carted, making straw and weeds into a stack of litter, for it could not be wholesome food, and was quite unfit for cutting up into chaff. Strongly as we approve of binding corn up in sheaves, in this instance it was decidedly wrong. But then the whole thing was a mistake, and it was quite clear that neither autumn tillage nor spring hoeing had any attention at that farm.

Northern farmers, groaning under the difficulties of another wet season, may be surprised to hear that the few days' rain in the midst of harvest were most welcome to midland and southern farmers; the soil on some farms having become so hard from drought that using anything like a skim-coulter was out of the question, and even ploughing was difficult. Implements now work freely in the moistened soil, and the weed seeds germinate quickly, very shallow stirring, just sufficient in fact to mix the fallen seeds with the surface soil being followed by speedy growth, which will destroy a host of annual weeds that otherwise would require hand-hoeing among the corn next spring.

Winter Vetches should now be sown, and it is a good plan to make other sowings early in October, and again late in that month, for this is a most useful green crop, either for mowing for cattle and horses, or for folding with sheep. Winter Oats may be mixed with it if cared for; but we prefer the Vetches alone. Drill in the same manure as for winter corn to obtain a full crop, which is most profitable, and may be turned to account in a variety of ways.

REMARKS.

- 4th.—Fine and sunny throughout.
5th.—Fine sunny day; misty evening.
6th.—Misty early; sunny morning, with occasional cloud; overcast after noon.
7th.—Generally overcast in morning, wet after noon.
8th.—Bright and sunny throughout.
9th.—Cloudy morning; overcast afternoon and evening.
10th.—Overcast all day; rain in evening.

A pleasant, seasonable week, but temperature a little below the average.—
G. J. SYMONS.

WE have received a carefully prepared and, we believe, thoroughly accurate record of experiments in the prevention of the Potato disease, which can scarcely fail to be of wide interest, and our readers can draw their own deductions from the facts set forth. As will be seen, the varieties of Potatoes are those in general cultivation, and are not restricted to Messrs. Carter's specialities. They embrace early, midseason, and late sorts, the object in view being to have a trial as fair as a trial could be, conducted entirely by Mr. H. F. Moore, Editor of the "Mark Lane Express" and "Bell's Weekly Messenger." Mr. Moore, having had experience in France in combating the Potato disease, determined to follow with precision the practice of his friend M. Aimé Girard. Though a drenching rain occurred three days after the dressing was applied it did not wash off the mixture, as it was apparent enough when we examined the plots ten days subsequently. At that time there was no disease, and the dressing appeared to have appreciably arrested the growth of the plants, therefore the non-dressed plots looked rather the better of the two.

It began to be feared that labour and material had been wasted, but the heavy rain on August 27th and 28th was followed by a decided outbreak of the murrain. The tops on the undressed plots speedily collapsed, while on the dressed plots they continued growing. This prolonged growth had the happy result of both increasing the total yield of the produce and diminishing the extent of the disease. This is clearly shown by the figure on page 263, and the difference was even more striking when the crops were examined on the ground. On the undressed plots they were in large unsightly heaps; on the dressed plots, a mere handful in comparison, or to be exact, 11 lbs. against 6 cwt. 3 qrs. 11 lbs. The total gain in sound produce is at the rate of nearly or quite 2 tons per acre, the actual gain on less than half an acre being 18 cwt. 19 qrs. 18 lbs. The cost of the dressing, including material and labour, was at the rate of £1 an acre, therefore the investment proved decidedly profitable.

RECORD OF EXPERIMENTS.

For six years past the French Government have been making experiments, under the direction of Dr. Aimé Girard, in order to test the value of the Bouillie Bordelaise as a preventive of the dreaded Potato disease (*Phytophthora infestans*), and in the early part of last year that distinguished chemist was able to report that the results year after year had been so satisfactory that the mixture might with confidence be recommended as a preventive of the disease. Since then a number of experiments have been made not only in other countries of Continental Europe, but also in the United Kingdom, with varied results, and this year Messrs. James Carter & Co., the well-known seed firm, of 237 and 238, High Holborn, London, W.C., decided to devote an acre of land on one of their seed farms at Bromley, in Kent, to an experiment, and further, that it should be conducted on identically the same lines as those on the French Government Farm at Joinville-le-Pont. The direction was put in the hands of Mr. Henry F. Moore, the well-known agricultural writer, who consulted M. Girard, in order that the chemicals used might be of the same strength and quality as those used in France.

The experiment was made on a field of a little less than an acre of Potatoes, which were planted in ten long double rows on April 8th, the drills being 36 inches apart, a distance which Messrs. Carter believe will be found more remunerative than if planted more thickly, as it permits the rays of the sun to penetrate the bed,

an important factor in the development of this crop. The varieties plan'd were as follows:—

- Row No. 1.—Myatt's Ashleaf.
 " " 2.—Snowdrop.
 " " 3.—Beauty of Hebron.
 " " 4.—White Elephant.
 " " 5.—Carter's King of the Russets.
 " " 6.—Carter's Cosmopolitan.
 " " 7.—Carter's Improved Magnum Bonum.
 " " 8.—Bruce.
 " " 9.—Carter's Surprise.
 " " 10.—Imperator.

The whole piece was divided into four equal parts, of which the first and third were dressed with the Bouillie Bordelaise, and the second and fourth left undressed. The strength of the mixture was as follows:—

22 lb. of sulphate of copper,
 22 lb. of unslaked lime, and
 100 gallons of water;

this being the quantity necessary for an acre of Potatoes. The sulphate of copper is of 98 per cent. purity, and is the Macclesfield patent sulphate of copper, this being the same as that used by M. Aimé Girard in his experiments. For the purposes of the experiment the first and third quarter were dressed with the Bouillie Bordelaise on July 11th and August 2nd, and the second and fourth left undressed. The mixture was applied by the Antipest, the new knapsack distributor, invented by Mr. G. F. Strawson, which did the work admirably. On the second occasion, a German machine was also tried, this also doing good work.

During the period of the experiment the weather has been as follows:—

APRIL 8TH TO 30TH.—Rainfall: 1.50 inch (on ten days). The rain fell on continuous days from 24-25th to 28-29th (0.55 inch).

Frost was registered on thirteen occasions from April 10th to 30th, in intensity ranging from 1° to 7°.

Severe snowstorm 1 A.M. to 8 A.M. April 16th.

MAY.—Rainfall 1.46 inch (on ten days). Very little rain (0.21 inch on eight days) until after the 24-25th; and on the 25-26th there was registered 0.97 inch.

Frost registered on May 1st (5°), May 7th (4°).

JUNE.—Rainfall 2.64 inches (on fourteen days). Thunderstorm 28th 8.30 P.M. to 11 P.M. Thermometer, lowest, 35°; highest, 98°.

JULY.—Rainfall 2.53 inches (on eight days). Very severe thunderstorm on the 14th, 10.15 A.M. and 12.30 midday, when 0.90 inch of rain fell. Thermometer, lowest, 39°; highest 90°.

AUGUST.—Rainfall 3.35 inches (on sixteen days); the heaviest fall was 27-28th, 0.98 inch. Thermometer, lowest, 38°; highest, 98°.

SEPTEMBER 1ST TO 14TH.—Rainfall 0.57 inch (on seven days). Thermometer, lowest, 35°; highest, 83°.

Early in this month (September) it was clear that disease had appeared in the undressed portions, and on September 6th one root was dug from the centre of one row of each variety in the first three sections. In the dressed sections only two diseased tubers were found in the twenty roots dug, and those were in the one root of Myatt's Ashleaf. On the other hand, of the ten roots dug in the section not dressed, in four cases all the produce was found to be diseased, in two cases slightly diseased, in one case very slightly diseased, and in only three cases—The Bruce, Carter's Surprise, and Imperator (vigorous growers)—was the produce found to be all sound. In other words, 90 per cent. in one of the dressed sections and 100 per cent. in the other dressed section were found to be all sound and good produce, and in the case of the undressed section only 30 per cent. were sound.

On Thursday and Friday last the crops were dug, when the following were found to be the condition and weights of the different varieties of Potatoes on the four quarter plots:—

FIRST QUARTER PLOT.—DRESSED.

Row and variety.	Weight of sound tubers			Weight of diseased tubers.			Total.		
	cwt.	qr.	lb.	cwt.	qr.	lb.	cwt.	qr.	lb.
1. Myatt's	3	1	5	—	—	1½	3	1	6½

7. Magnum Bonum	3 0 21	— — 5	3 0 26
8. The Bruce.....	3 2 0	— — 7	3 2 7
9. Carters' Surprise	2 1 10	— — 25	2 2 7
10. Emperor	3 2 23	— — 16	3 3 11
Totals	26 0 9	3 2 11	29 2 10

THIRD QUARTER PLOT.—DRESSED.

Row and Variety.	Weight of sound tubers.	Weight of diseased tubers.	Total.
	cwt. qr. lb.	cwt. qr. lb.	
1. Myatt's	1 1 13	— — 0 $\frac{1}{4}$	1 1 13 $\frac{1}{4}$
2. Snowdrop	1 1 21	— — 0 $\frac{1}{2}$	1 1 21 $\frac{1}{2}$
3. Beauty of Hebron ...	1 3 12	— — 1 $\frac{3}{4}$	1 3 13 $\frac{3}{4}$
4. White Elephant	2 3 17	— — 0	2 3 17
5. King of the Russets...	2 2 9	— — 0	2 2 9
6. Cosmopolitan	1 2 7	— — 0	1 2 7
7. Magnum Bonum	2 3 0	— — 0	2 3 0
8. The Bruce.....	3 0 23	— — 0	3 0 23
9. Carters' Surprise	2 2 0	— — 0	2 2 0
10. Emperor	2 3 8	— — 0 $\frac{1}{4}$	2 3 8 $\frac{1}{4}$
Totals	22 3 26	— — 2 $\frac{3}{4}$	23 0 0 $\frac{3}{4}$

FOURTH QUARTER PLOT.—UNDRESSED.

Row and Variety.	Weight of sound tubers.	Weight of diseased tubers.	Total.
	cwt. qr. lb.	cwt. qr. lb.	
1. Myatt's	0 3 14	— 1 14	1 1 0
2. Snowdrop	0 2 26	— 2 14	1 1 12
3. Beauty of Hebron ...	0 3 16	— 2 23	1 2 11
4. White Elephant	1 0 14	— 3 7	1 3 21
5. King of the Russets...	1 2 0	— 1 0	1 3 0
6. Cosmopolitan	0 3 5	— 1 0	1 0 5
7. Magnum Bonum	1 0 20	— 0 1	1 0 21
8. The Bruce.....	3 1 11	— 0 2	3 1 13
9. Carters' Surprise	1 1 0	— 0 14	1 1 14
10. Emperor	2 1 7	— 0 20	2 1 27
Totals	14 0 1	3 1 11	17 1 12

The following table gives the totals of the two duplicate experiments:—

	Dressed plots.	Undressed plots.	In favour of dressed plots.
	cwt. qr. lb.	cwt. qr. lb.	cwt. qr. lb.
Weight of sound tubers...	58 0 0	40 0 10	17 3 18
Weight of unsound tubers	— — 11	6 3 22	6 3 11
Total yield	58 0 11	47 0 4	11 0 7

It will thus be seen that in whatever aspect the experiment is looked at it is in favour of the dressing by the Bouillie Bordelaise. So far as sound tubers are concerned, the yield is over two tons per acre more than in the undressed portion (the two plots being less than half an acre), while the quality of the tubers is better.

On Friday last a large number of persons interested in the subject carefully examined the crops on the ground immediately the work of lifting and weighing was completed, and there was an unanimity of opinion that the trials were well planned, well carried out, and conclusively in favour of *Bouillie Bordelaise*, when properly prepared and applied, as an antidote of the Potato disease. Its effect on the plants is shown in the illustration from a photograph taken across the ground where the ends of the dressed and

undressed rows meet at the line of sticks. The difference is so striking, that—to cite the words of an old Potato grower who was prejudiced against the “doctoring”—“there is no getting away from it.” Messrs. Carter & Co. will presumably dress the whole of their Potatoes next year, except perhaps a few patches here and there for “taking the disease,” as they like making experiments for public enlightenment.

NOTES ON HYACINTHS.

At our spring exhibitions the Hyacinth is the chief source of attraction amongst bulbous plants. When staged in the best possible condition few plants can equal it for compactness and beauty.

Bulbs that are imported vary from three to five years of age. The very best should be the latter. Quantities that are annually sent to this country as fully developed bulbs would probably be better if grown for another season or two. Be this as it may, good bulbs are of the first importance if large spikes of fine flowers are to be produced. It must be remembered that the condition of the bulb at potting time has much to do with the success of any exhibitor. If a start is made with bulbs that are poorly grown, badly developed, and imperfectly ripened, however well they may be grown, the exhibitor has but a poor chance in competition with another who starts with roots of the first quality—that is, bulbs which have been grown to their full size and have been thoroughly developed and properly ripened.

How are we to distinguish good from inferior bulbs for this purpose? By what must we be guided in making a selection? Large bulbs are not always the best, therefore size is no criterion of development and solidity. Bulbs that are capable of producing fine spikes should be firm and solid; they should scarcely yield to the pressure of the thumb close to the crown, and should be heavy for their size. They can almost be judged by their weight. Bulbs secured from a reliable source, solidity, and weight are the points desirable. A small bulb is often heavier than a large one of the same variety. In the selection of bulbs some knowledge of the size they naturally attain should be possessed by those to whom the selection is left.

Intending exhibitors must not, however, be misled by supposing that the secret of gaining the post of honour in competition with others depends solely upon having first-class bulbs to commence with. This is not the case; however good the bulbs may be they need growing, and the most careful treatment during the season of growth. I am certain that a person with second-rate bulbs well grown would easily beat first quality bulbs grown in an inferior manner. Although large spikes and bells, combined with colour and freshness, go a long way, they do not always carry the exhibitor to a successful issue. They need all these qualities, and in addition should display at a glance that they have been grown well and staged at the exact time they are at their best. Some judges place considerable importance on the condition of the spike alone, but my contention is that the spike is only part of the plant to be judged. A well grown plant with a slightly inferior spike, as regards size, must of necessity often be placed before a poorly grown plant with a large spike. Those familiar with the culture of Hyacinths can detect almost at a glance whether an inferior spike is due to cultivation or to the condition of the bulb before it was potted.

What constitutes a well grown Hyacinth plant? It should be dwarf according to the variety; the flower spike should be stiff almost capable of supporting itself without a stake; the spike should be large, well lengthened out, with bold bells that furnish it without crowding. As the varieties differ widely in this respect, each should be judged according to its individual merits. The foliage should also be stiff with a dark healthy green appearance. It should reach to the base of the spike, or an inch or two above it, and the tips in many cases should bend out slightly. Every Hyacinth does not assume this habit, but the foliage is upright and inclined to arch towards the spike. When the point of every leaf is slightly turned outwards throughout a collection it may be safely inferred that they are not natural, but have been turned out by the exhibitor. In some cases the tips of two leaves only will turn outwards, in others four, and so on, while the remainder invariably stand upright. A good spike should be even all round from top to bottom, the base should be even, and the top of the spike well filled with well developed bells, which should be as even as possible throughout.

What concerns cultivators most is the methods of culture that should be followed throughout, in order to produce examples as near perfection as it is possible to grow them. In detailing these

I shall begin at the beginning, and dispose of each item of culture in rotation as far as is practicable. Some may think the potting of the bulbs is the first matter, but it is not. The intending grower should have on hand previous to potting a good stack of loam, which has been stacked for four or six months, and a heap of cow manure that has been stored sufficiently long in a shed to allow of its being rubbed through a fine sieve without the least trace of stickiness about it. I do not care for stacking the manure with the loam unless the latter is dry when it is stacked; if it is moist the manure adds to the evil, and the heap when cut into is the reverse of being as sweet as it should be. A good heap of refuse soil from the potting shed should also be reserved in readiness. This would consist of sandy soil from plants that had been grown for a limited period only in a rich compost. I am not in favour of using loam in a fresh state for Hyacinths; it must be remembered that their life is but a short one, and the fibre of the loam has not time to decay sufficiently to be of much use to the plant before the work for which it is grown has been accomplished. For years we found that Hyacinths did as well if not better in soil that had grown plants or a crop of fruit as in fresh loam; in fact we prefer the rich compost from various sources that accumulates, or can be accumulated in all gardens. This is passed through a sieve, and portions of crock or other rubbish removed. To this is added one-fourth of fresh loam, such as I have described, and one-seventh of cow manure as finely divided as possible. Hyacinths dislike manure in a practically fresh state. Sand should be added according to the texture of the loam and the amount of gritty material that may have been used in the old compost. Hyacinths like a rich and sandy soil, which is certain to remain sweet and is thoroughly porous. The compost when mixed up should be in an intermediate state for moisture, so that no water will be needed until the bulbs have grown and rooted sufficiently to be removed from the plunging material.

Five-inch pots are most suitable for single specimens; one good crock at the base is ample. Over this a thin layer of cow manure should be placed, the same as that advised to be mixed with the soil. I have said a thin layer, for too much would do more harm than good. The soil should be pressed moderately firm into the pots, and the crown of the bulb should be just level with the soil, which should be half an inch below the rim of the pot. Whether a pinch of sand should be placed just below the bulb is an open question. I have done it, and for years looked upon this time-honoured practice as a necessity. But of late years I have come to the conclusion that it is only a waste of time and of sand. I found no good to result from this practice, and consequently discontinued it.

When should the bulbs be potted? is a natural question to ask, and one that can only be answered in a general way. Much depends upon the time they are wanted for exhibiting. It is a mistake to keep them out of the soil until they display signs of growing, for then injury results. They should not be left in the bags in which they may be received if sawdust or buckwheat chaff has been used as a medium for packing; the slightest damp will induce them to commence root activity. For most of our shows the beginning of October is a good time to pot the bulbs, and on no account should potting be delayed after the end of the month.—W. BARDNEY.

(To be continued.)

EULOPHIELLA ELISABETHÆ.

THE courtesy of M. Lucien Linden enables us to present an engraving (fig. 35) of the beautiful novelty *Eulophiella Elisabethæ*, introduced by L'Horticulture Internationale, which proved so distinct that Mr. Rolfe could find no place for it in any existing genus, and therefore made it a genus of itself. It formed plate 325 of the May number of *Lindenia*, in which it is fully described. It has the habit of a *Catasetum* or *Eulophia*. "It produces a long horizontal stem, furnished with a score or so of most beautiful

flowers. The sepals and petals, which are stout in substance and distinctly rounded, are white tinted with rose; the broad, three-lobed lip is of the same shade, and bears at its base a bright orange callus; the back of the segments is coloured with a beautiful reddish brown, as well as the floral stem itself. The engraving gives a good idea of this fine novelty. The flowers have the dimensions of those of *Odontoglossum crispum*, or of a large *O. citrosimum*, a species of which they somewhat recall the elegant rounded form. They exhale a delicious perfume.

FIG. 35.—EULOPHIELLA ELISABETHÆ.

Eulophiella Elisabethæ, which is dedicated to the Queen of Roumania, was exhibited at a meeting of L'Orchidée in spring, and was unanimously awarded a first-class "diplôme d'honneur."—"Le Journal des Orchidées". It is recommended that the plant be grown in a warm house, and it is stated to succeed under the treatment required for *Phajus*, *Eulophia*, and *Cyrtopodium*.

HABENARIA MILITARIS.

THOSE readers who paid a visit to the meeting of the Royal Horticultural Society at Westminster on Tuesday, September 6th, no doubt noticed the very fine basket of this lovely *Habenaria* exhibited from the collection of Sir Trevor Lawrence, Bart., Burford Lodge, Dorking. Although *H. militaris* has been exhibited on several occasions during the past few years, very few people seem to possess it. It is easy of cultivation, but failures occur because the plants do not receive the attention they require during their resting period. The specific name implies a military appearance, doubtless given on account of the erect spikes and bright coloured flowers. I believe the plant was first introduced by M. Godefroy Lebœuf from Cochin China in 1886. The leaves are linear, acute, 8 inches long, and half an inch broad. The plants when flowering vary from 6 to 12 inches in height, in fact there seem to be two varieties, one half as tall again as the other. The spikes are erect, and carry twelve to eighteen flowers; the sepals and petals are greenish and form a kind

of helmet; the lip is large and spreading, very bright scarlet; the spur and the bracts on the stem are very curious. When growth has commenced the tubers should be potted into small pots (60's) in chopped peat and sphagnum mixed with sand. A stove temperature and plenty of moisture with a position near the glass will suit them. The plants commence to flower at the end of August and last in beauty about a month. Soon after the flowers have faded the plants commence to die down, and as they are entirely deciduous water must be withheld; to keep them through the resting period is the hardest part of their cultivation. With the two or three plants I have had to do I find that they require resting in a stove temperature on a shelf. It is a good plan to place the pots containing the plant in a pot a size larger, and fill the space between with sand. The moisture in the house prevents the sand from becoming quite dry, and it in turn prevents the tubers from being shrivelled up, obviating the necessity of watering, and so preventing damping off.—C. K.

HABENARIA CARNEA.

By the side of a plant of *H. militaris* and in contrast to it a plant of *H. carnea* is flowering in the warm Orchid house at Kew. Its requirements are the same as the above, but it does not need to be dried off. The leaves, which are 2 inches long by 1 broad, are dark green, plentifully marked with white spots. The spike is about 8 inches high, carrying six or eight large flowers, white with the faintest tinge of pink. The spur attached to each flower is about 3 inches long. This plant flowered at Kew for the first time last year, and was sent to that establishment by Mr. Curtis of the Penang Botanic Gardens, who, I believe, found it in the Langkawi Island. If *H. carnea* could be successfully introduced in quantity we should have a splendid companion to *H. militaris*, but at present it is new and rare.—C. K.

CÆLOGYNE FLEXUOSA.

THIS species is a member of Lindley's group *Flexuosæ*, and is allied to *C. simplex*, *Lindl.* and *C. suaveolens*, *Hook. f.* From the former, however, it is readily distinguished by its sharply hexangular ovary, broader petals, and the more slender keels of the lip; from the latter by the narrower petals and the straight, not very undulate, keels of the lip; and from both by its habit of producing the scapes from the summit of the nearly mature pseudo-bulbs between the leaves, not from the young growths. It is a native of Java, and was presented by the Botanic Garden at Leyden to the Kew collection, where it flowered in April of the present year. It was also received from Mr. F. W. Moore, Glasnevin Botanic Garden, Dublin, as a Javan species, as long ago as May 1889, when it could not be determined. The flowers are white with a light yellow stain across the middle of the lip, which is extended as a narrow line on either side of the disc to near the base, at which point the lip is very sharply constricted, producing a narrow transverse channel underneath.—("Kew Bulletin.")

ONCIDIUM CRISTATUM.

A distinct and pretty species introduced from Brazil by Messrs. Linden, L'Horticulture Internationale, Brussels, which flowered in April of the present year, and was sent to Kew for determination. It is allied to *O. Schillerianum*, *Rehb. f.*, and *O. Volvox*, *Rehb. f.*, with which it agrees in its somewhat twining scape. The sepals and petals are reflexed, undulate, and of a clear bright yellow, the lip a little deeper yellow with a row of suffused red-brown dots on either side of the crest, and the column-wings deep yellow. The crest consists of five parallel cristate-crenulate keels, the two outer ones being longer, and the two next considerably shorter than the middle one.—("Kew Bulletin.")

CYPRIPEDIUM PUSILLUM.

This is a curious little species, closely allied to *Cypripedium fasciculatum*, *Kellogg*, a native of California and Oregon, being in fact the only other member of the section *Diphyllæ* with racemose flowers. The present species, however, is a much smaller plant in every respect, barely exceeding 4 inches high. The flowers are light yellow, longitudinally veined with dull brownish-purple, with a light yellow lip; they become more purple as they fade. The infolded margin of the lip, which is strongly infolded round the mouth, is at the base suddenly turned out and reflexed. A plant was purchased for the Kew collection in May last, without any record of its origin, but shortly afterwards it was sent for determination by H. J. Elwes, Esq., of Cirencester, who had received it with the information that it came from Florida. It has also flowered with Messrs. F. Sander & Co., of St. Albans.—("Kew Bulletin.")

INSECTS OF THE FLOWER GARDEN.

(Continued from page 96.)

SPACE did not allow me, in the preceding article, to complete the history of those lively little visitants or dwellers in our gardens, the gall-gnats, otherwise *Cecidomyiæ*, and I now append a few more facts about them. I have called them lively, and so they are when winged, but as larvæ they are very slow in their movements; as a rule, indeed, those that live within galls only quit them to descend to the earth, then they are said to move rapidly. Some of the tiny larvæ, however, turn to pupæ without quitting the gall, in which they spin a slight silken cocoon. Obviously, the galls made by these insects on leaves are more frequently noticed than the enlargements they produce on the stems of plants, or in unexpanded buds, which are apt to be passed by as natural peculiarities of the plant. Some deformed buds, such as those sometimes seen on *Fraxinus* species, contain several *Cecidomyiæ* living in a sort of "happy family" condition. What is more singular still, some galls serve as abodes for two larvæ of different species, the egg producing the second larva being deposited when the first is partially grown. How the couple arrange matters is doubtful; some entomologists think one of the two dies eventually, a single fly emerging from the larva which has been stronger, and has possibly devoured the other or else starved it out. Some wonder has been expressed how these slender, seemingly feeble, flies can release themselves from the galls if it has happened the pupæ have remained in them. It appears they are helped in getting out by their antennæ, which are horn-like at the base, also they obtain leverage from spines situate on the abdomen.

One remarkable fact is stated about a few species of this group; they are, like the aphides, viviparous, and false eggs form in the bodies of some of them, which increase till the larvæ become distended with young larvæ resembling themselves. Such *Cecidomyiæ* have occurred under the bark of trees, in the cones of Pines, and in fungi. Though, as a rule, the larvæ of this group prefer living plants, gall gnats have been reared from decaying bulbs of Tulips and Hyacinths. Then there are other species, which some have placed in a genus by themselves and named *Diplois*, and which live upon, not in, leaves; they are presumed to feed upon plant lice, possibly also upon mites. These are colourless, usually, and transparent, or nearly so; the last ring of the body is spiny, and by the help of the spines occasional leaps are made by the larvæ in pursuit of their prey. These must be considered useful. Some of the flies haunt flowers, and, small as they are, it is supposed they assist the impregnation in some instances, because they can enter blossoms, from which their own size excludes bees and larger flies. In leaving these, I should add that the former has a terrible enemy amongst them, the Wheat midge, or *C. tritici*, and to the same group belongs the Hessian fly, so-called.

We pass now to flies of somewhat different form, rather stouter, though allied to the gnats and midges. Several of these in their larval state occur amongst manure, especially vegetable, but one of them is notably a pest wherever it turns up, because it makes the roots of plants the object of its attack. From some odd reason, this fly has received the name of St. Mark's fly, or *Bibio Marci*, but I do not think gardeners generally recognise the insect by this or any other particular name, as the larva is seldom distinguished from similar root-feeders, such as those of the crane fly tribe. In the fly, which is small, the males and females have heads very unlike. The former have eyes so large and prominent that they seem to occupy almost the whole front of the head. The larva or grub of *B. Marci* is slender, brown in colour, muscular, and clothed with short, stiff hairs, which serve instead of legs. It sometimes infests the Strawberry, and in the flower garden burrows at the roots of the Larkspur, *Ranunculus*, and other favourite flowers. Not unfrequently these larvæ run tracks for a long distance underground, perhaps for the sake of meeting sociably, since they have now and then been found in parties of from ten to a hundred packed closely together. This pest may be destroyed by the application of petroleum, suitably diluted; it is also killed by hellebore tea.

Passing by the great host of gnats and midges which are, in their larval state, of aquatic habit, yet which come to our gardens either to visit the flowers or to act as bloodsuckers if they have opportunity, I mention one little creature which we frequently see on the windows of our plant houses in autumn and winter. It rejoices in the Latin name of *Psychoda phalænoides*, because it is supposed to look rather moth-like, with sloping, broadish wings, which have tiny hairs and black bands. It runs and hops briskly if alarmed, and comes from a larva which lives upon manure. The Tipulidæ, or crane flies, are long-legged and long-bodied. Their lankiness makes them also share with a species of spider the name

of "Daddy Long-legs," and the easy, indifferent way in which they throw off or drop their limbs apparently for slight causes is a matter of common remark. But when we see one moving amongst blades of grass we perceive at once the advantage they derive from these legs, which are prehensile as the fly moves, and enable it to glide along rapidly, while it maintains an upright position. This is particularly advantageous to the female fly, as this frequently resorts to lawns and fields of grass. She has a sharp egg-placer or ovipositor, and sits on the stem of some grass, then steadily works this instrument into the soil, depositing eggs in the holes made. Extensive patches of ground are sometimes laid bare by the larvæ of Tipulæ, though it may happen that the grass is improved where they are few in number through the removal of superfluous roots. Clover and cornfields are also visited by this insect as well as the kitchen garden, and in our beds and borders there are often to be noticed signs of its presence at the root of some choice flowers. It has been observed to single out for attack the Carnation and the Dahlia. There are numerous species, but of these only four seem to be injurious—viz., the abundant and familiar Tipula oleracea; the giant crane fly, T. gigantea; the spotted crane fly, T. maculosa; and the marsh crane fly, T. paludosa.

Some gardeners have suffered so much from the crane fly larvæ that they have given to the insect the name of *the grub* emphatically, and it has been called "leather jacket" from the toughness of its skin. The head is blunt, having two powerful jaws; the sides of the body are lithe and wrinkled; in colour it is usually greyish or brown. It would appear that the eggs are not hatched till the new year, generally about February. The greatest mischief is done by these larvæ during May and June; in July they have entered the pupal state. The pupa, or "fly-case," has spines by which the insect pushes itself through the soil to the surface. It has been said that the male flies emerge first and assist the females to extricate themselves from the case. Rolling, which is a successful means of reducing the numbers of the crane fly larvæ in fields, cannot be tried in the flower garden, and many applications tried, such as carbolic acid in solution, or one of sulphate of iron, if strong enough to kill them, are likely to damage the plants. A judicious application of manure to the roots has been proved to be serviceable, lessening the mischief done by these grubs, and where they have been caught attacking the stems just below the surface, a little lime put in a ring round them keeps the insects away. Some writers upon horticulture have expressed the opinion that now-a-days it is the fashion to water plants too freely; for one thing it is certain, as Miss Ormerod has pointed out, that the moister the soil is, the more do the Tipulæ thrive. It is in damp, low lying districts that they occur abundantly, and water has so little effect upon them that immersion in it for hours does not drown them.—ENTOMOLOGIST.

DISCUSSION ON APPLES.

VARIETIES of Apples change so much under the conditions in which they are grown, and several of them are so well marked by innate peculiarities, that information contained in notes from correspondents could scarcely fail to be interesting and useful. Mr. Bunyard gives a timely hint on the method of pruning that should be avoided for obtaining the best crops of the beautiful Lady Sudeley, and Mr. Molyneux warns against planting Keswick Codlin in strong soil. He also alludes to Frogmore Prolific, certainly one of the very best in growth and fruit at Chiswick this year, but it fails in some places. What is the cause? Is it the soil or the stock? A wide field is open for discussion about Apples, and the time is opportune.

LADY SUDELEY.

IN the *Journal* of September 8th, page 211, is a short note on Lady Sudeley Apple, which appears to me rather misleading; as Irish Peach has been past its season here for ten days, and Lady Sudeley is still good, they can scarcely be compared to each other. We gathered Lady Sudeley first about September 1st, and I send you six pulled to-day. We expect them to remain on the tree for ten days more. You can test their quality. They are most striking on the trees, being quite scarlet. I may add that they have a habit of growth like Golden Noble of fruiting at the tips, and giving often a foot of growth with no spurs, so that they require no pruning, so to speak, only a little regulating after a tree is once formed.—GEO. BUNYARD.

[The fruits received are much superior to those placed on the Committee table, and the quality distinctly better, which appears to show that it is best when gathered and eaten at once. They are the best Lady Sudeleys we have ever seen. The hint as to pruning should be noted.]

KESWICK CODLIN.

ON page 250 Sir John Sinclair is quoted as saying, "It flourishes best in a strong soil." That is exactly what this Apple will not do here, and our soil is strong enough without being actually clay. This variety is one of the worst we have among many; it bears any amount of fruit, but it is of poor quality, numbers not being larger than full-sized Walnuts even now. Young trees planted in November, 1890, have made but little growth; they have borne a quantity of fruit, but it is very much specked. In August the same year the fruit foreman of a large nursery remarked, "You ought to plant Keswick Codlin freely." I replied, "It is of no use here." He evidently thought it was, for he sent a couple of trees (those referred to above), with the result recorded.—E. M.

WARNER'S KING AND D. T. FISH.

AT one time I was inclined to think a trace of distinctness could be found in the fruit from trees named as above. A similar tree of each was growing not far from the other, and fruit from the latter exhibited more colour than that from the first, though little difference could be discerned in the position of the two trees. This year trees of Warner's King have fruited in an open field which have exactly the same characteristic features about them as had the fruit of D. T. Fish, which is enough to convince me that they are one and the same. With these also must be classed Nelson's Glory, which is identical with the original Warner's King, although our tree was received as distinct.—E. M.

FROGMORE PROLIFIC.

My experience with this variety coincides with that of the note on Apples at Chiswick by "P." (page 238), although I know of one instance where many trees of it have been cut over and grafted with another sort. With us the fruit is ripe now (September 15th). I like its appearance very much; it seems to possess all the characteristics of a good Apple.—E. MOLYNEUX, *Hants.*

ATTRACTIVE ARRANGEMENTS IN BEDS AND BORDERS.

DURING the autumn of last year notes from several gardeners were published of arrangements of flowers which they considered striking. As an instalment to any such notes that may be sent this year, the following may be of some interest:—

One set of beds has been devoted to Tuberous Begonias, a central bed being yellow, four outer groups crimson, and four others rose. They are in each case planted among a groundwork of *Königa variegata*. The strain of Begonia is called erect-flowering. Nothing could be more brilliant than these. They have been blooming since the end of June, and are now one sheet of large open blossoms. The yellow is less effective than the other colours.

Another group of beds which are very pretty are planted with *Calceolaria Kayi* and *Veronica Andersoniana variegata*, alternate plants. The flowers of the Veronica have a charming effect, and soften the rather gaudy hue of the Calceolaria. These are in juxtaposition to other beds of Henry Jacoby Pelargonium, and are, in each case, edged with a broad band of close-cut *Cerastium tomentosum*. I like these very much.

A set of borders, backed with large bush Apple trees, and having a broad grass walk between, running some 90 yards in length, is every season planted in a different manner. The present season there is an edge of white Lobelia next the grass, then a broad carpet composed of alternate plants of light blue Lobelia and Harrison's Musk. This is backed with a line of the best Pentstemons, and behind these among the trees is mainly Salpiglossis, a line of Phloxes forming the extreme back of the border.

All over the border, in the space between the white Lobelia and Pentstemons, are dotted a large number of plants which are now flowering. These consist of 250 Hyacinthus candicans planted singly, 600 Gladiolus brenchleyensis planted in tens, 200 Montbretias in tens, these being to the front, where there are also a few of the Dracæna-leaved Beet. There are also a few single plants of Prince's Feather and of Love-lies-bleeding, groups of Tiger Lilies at the back of the border, and some Acacia lophantha, variegated Maize, Liliun auratum, and Madame Desgranges Chrysanthemums, with here and there an Iceland Poppy. Notwithstanding some blanks among the Lilies, these borders have been, and will be for some time, very effective and interesting.

Many more plants might have been utilised, but there was a danger of overdoing the "dots." *Chamæpeuce diacantha*, Castor Oils, Lobelia cardinalis, Campanula pyramidalis alba, large plants

of *Veronica Andersoni variegata*, and 5-inch pots of *Marguerites* were some others I had in view. If too many are planted at first it is impossible to effect any alteration; but should there be any lack of plants it is a very simple thing to put more out as soon as a blank spot is noticed.—R. P. BROTHERSTON.

CELERY NOTES.

THERE is no disputing the fact that more Celery is spoilt during what may be termed a favourable season than during a hot and dry summer. This at first sight may appear incredible, but it is by no means so difficult to account for as may be imagined. Celery is a very moisture-loving hungry plant, and when once the trenches are well filled with roots there is little likelihood of too much water being supplied during the growing season. Showery weather and comparatively heavy rains are most misleading. Either the one or the other very frequently has the effect of stopping all watering operations, whereas nothing short of a thorough soaking rain, extending say over several hours, is sufficient to moisten the soil and manure about the Celery roots, and that only for a short time. When, however, the weather is hot and dry the watering pot is freely and frequently used by those who are anxious to grow good Celery, the consequence being that the latter gets all it requires.

The summer of 1892 cannot be said to have been favourable to the growth of good Celery, yet I can truthfully assert I never saw so many superior samples of it during one season in my life. It was not merely at one or two isolated shows that it was good, but I saw and tested exhibition Celery in various parts of the country, at cottagers' shows, as well as some of the most pretentious exhibitions, and it was the same everywhere. At the great Co-operative Festival at the Crystal Palace it was part of my duty to assist in adjudicating on the merits of two classes of Celery—one for white and the other for red forms. There were twenty-five entries in each, and out of the whole lot there were only two bad samples, bolting in all other cases being conspicuously absent, while the quality generally was good. In this instance, and also at several other shows, the Celery was exceptionally fine, and it is equally worthy of note that this remark does not apply to any particular variety or varieties, quite a number of so-called distinct forms being equally well represented.

The foregoing only goes to corroborate assertions that I have previously made in these pages—viz., that much Celery is spoilt or caused to bolt prematurely on account of dryness at the roots, and this not so much during the hottest part of the summer, but rather during September and October. When once the first moulding up has been given few think of watering Celery, yet it requires it as much then probably as at any period of its growth. This assertion can be easily proved or disproved. All that is necessary is to probe deeply and somewhat roughly, some of the soil and roots to a good depth being brought to the surface. If it is found to be in a thoroughly moist state all well and good, no harm being done either way; but if, as is more likely, it proves to be very dry, a good soaking of soft water, soot water, or liquid manure ought to be given at once, even if it is raining at the time, this being repeated once or twice before more mould is banked up around the stems.

Those who follow the good old practice of laying a pipe drain along the trench are the least likely to neglect to give autumn waterings, pouring large quantities in at the highest end being a simple and, I might say, a tempting proceeding. In very many soils and positions Celery roots are found to be very dry when dug at midwinter or later, and it is questionable if a soaking ever takes place after once moulding up is well advanced. The other extreme would most probably be even more injurious, frost proving destructive or more penetrating when it can act upon moist soil; but there is no likelihood of any moisture applied during September or the succeeding month long remaining unappropriated by the abundant and absorbing Celery roots in trenches.

Sites of old Celery trenches are supposed to be very suitable for rows of Peas during the following season, but, as far as the manure is concerned, there is not much left of that after the Celery has done with it. If my advice then is taken the Celery rows will not be neglected, but should receive occasional moistenings at the roots for some time longer, the last being given, if need be, just prior to the final moulding-up. Much of what would otherwise have been good Celery is also spoilt in the moulding-up. Not only must the stems and hearts be well blanched, but it is of equal importance that these be kept as intact and clean as possible. The grower for exhibition, if he is wise, effects perfect and cleanly blanching by means of several folds of brown paper, or even ordinary newspapers, the latest Celery also having an additional bandage of canvas or sacking to preserve the paper and keep out frosts. Any not so carefully blanched stands but a poor chance of winning a prize, the contrast in favour of that not moulded-up being most marked. In the case of the bulk grown for ordinary purposes there is less need for resorting to extraordinary blanching processes, good presentable Celery being the most simply produced in the ordinary way—that is to say, by gradually moulding-up.

In heavy soils, more especially, slugs are very troublesome, greatly disfiguring the outer stalks, and not unfrequently the hearts, after the soiling-up has been completed. A free use of fine ballast, charred clay or other burnt soil, and ashes, the stalks being surrounded by either of these, effectually excludes slugs, and the Celery keeps well in it. It is not so very much of this that is needed, the way to use it being to place

boards on either of the rows, filling-in with the slug-preventing material, and drawing out the boards after some of the ordinary soil has been well banked up to them. A little fine soil added is also of good service when the garden soil is hard and lumpy, the method of proceeding being exactly the same as that just described. Our ground being in fairly good order, and slugs fewer in number than usual, all that is being done by way of keeping away the latter consists of using soot very freely about the Celery each time more soil is added. Cooks and butlers sometimes object to the sooty Celery, but the soot washes off readily enough if only a little trouble is taken, and soot and Celery certainly agree well together.

It is possible to be either too early or too late in moulding up Celery. If the soil is placed around the stems much in advance of heart growth, the latter is liable to be pinched for room, bulging and splitting as a consequence taking place at the base. If left too long before soiling up commences the outer stalks open out badly and cannot be brought up together neatly without many of them splitting. It is also possible to be too late in completing the moulding up, sharp frosts catching a good length of unprotected tops, early decay resulting. If well banked up before severe frosts are anticipated only a little more than the tips of the leaves being left out, no further protection is often needed, the Celery keeping well without it. At the outset the smaller lower leaves, suckers, and weeds should be cleared away from the plants, the outer leaves being then drawn well and neatly up together, and either temporarily tied or held by a pair of hands while one or two other assistants break down the soil and place about 3 inches in the trench. Then as the centre fills up take the same precautions as to holding or tying the outer stalks well up together, so as to effectually exclude soil from the hearts, and add another 3 inches or rather more of soil, avoiding unduly pressing against the stalks.

After an interval of three weeks or so the final moulding up may take place, and this time it should terminate in a neat ridge, so as to throw off heavy rains and snow water, as it is not about the stalks that moisture is needed, and it is also advisable to pack the soil somewhat firmly about the leaves.—W. IGGULDEN.

POTTING WINTER-FLOWERING PLANTS.

No time should be lost in potting the various kinds of winter-flowering plants which were planted out in prepared holes or trenches towards the end of May or early in June last, lest they should get nipped by frost, which they would run a risk of doing if left in the open for a week or two longer.

The first to require attention in the direction indicated is the *Bonvardia*, which is one of the most useful as well as the most easily cultivated winter-flowering plants we have. Having decided on the size of pots into which the plants are to be placed, and which, in a general way, range from 9 inches in diameter to 6 inches, place in from 2 to 3 inches of potsherds, putting a large piece over the hole, and making up the depth indicated with two or three smaller sizes, putting the smallest on the top and over them a handful of half-decayed leaves, a layer of moss, or coarse loam. This done, ring round the plants with a spade at from $4\frac{1}{2}$ to 3 inches from the stems, according to the size of the plants and the pots into which they are to be placed. Before potting cut off all straggling and damaged roots.

Use a compost of four parts light friable loam and one of leaf mould and peat, with sufficient sharp sand to render the whole porous, working it well in between the ball and the pot with a flat rammer, making the soil moderately firm at the top and sides, and leaving a space of an inch at the top for water. Then stand the plants on sifted coal ashes in a cold pit or some other suitable place where they should be shaded from sunshine for a few days, and protected from frost. Give water at the roots to settle the soil about them, and afterwards repeat the application as occasion may arise. Syringe the plants lightly on bright afternoons for about a week, until they have quite re-established themselves. After this the shading should be discontinued and a free circulation of fresh air be admitted to the plants during bright days, drawing up the sashes in the evening and covering them with mats until the time for putting the plants into a forcing house arrives. This must be determined by the time they are required to be in full flower. If at Christmas it would be advisable to put a portion, if not all, of the plants into heat towards the end of October. From that date until the flowering period arrives weak applications of tepid liquid manure should be given, together with occasional surface dressings of Thomson's or some other approved plant manure immediately before applying clear tepid water. Plants thus treated, assuming that they had been well attended to in the way of stopping and giving water at the roots during the past three months, will yield a profusion of deliciously scented flowers in due time. When put into the forcing house a minimum temperature of 55° to 60°, according as the weather is cold or mild, should be observed, afterwards increasing it four or five degrees if necessary to hasten the plants into flower.

Richardia (Calla) aethiopica should next receive attention in the manner described above. The compost in this case should consist of four parts sound fibry loam (where obtainable) and one of horse droppings, with a dash of coarse sand. The large fleshy roots will soon push into this mixture, and, being a gross feeding plant, liberal supplies of tepid liquid manure should be given at the roots during the forcing and flowering period in order to obtain a good succession of large well-developed flower-spathes. Occasional fumigations on calm evenings with tobacco paper will be necessary to rid the plants of aphids, to the

attacks of which they are liable when subjected to the somewhat close warm temperature of a forcing house.

Marguerites, Eupatoriums, Salvias, *Schizostylis coccinea*, and *Deutzia gracilis*, where planted out during the summer months, should also be potted in the manner indicated, putting tufts of the *Schizostylis* into 4½-inch and 6-inch pots, as these are the most convenient sizes for decorative purposes. The *Schizostylis* is an excellent decorative plant, the small spikes of Gladiolus-like scarlet flowers thrown up well above the grass-like foliage show off to great advantage when associated with flowering plants of *Bouvardia Humboldtii corymbiflora* (white), and such plants. By potting the *Deutzias* at once the plants have time to thoroughly re-establish themselves in the pots before they have shed their leaves; this is preferable to potting them immediately after the fall of the leaf for putting into the forcing house shortly after.

In conclusion, it is very advantageous to all the plants named that they should have a good interval of rest before being introduced to the forcing house, as better results are obtained. I may also add that the cultural remarks given above as to shading and watering at the roots are applicable to all the plants mentioned.—H. W. WARD.

CABBAGES, SPRING VERSUS AUTUMN PLANTING.

THE severe winters we have recently experienced have brought forcibly to the minds of gardeners the necessity of paying special attention to the production of spring Cabbages, and considering the probability there is of having another trying winter it behoves us to review the methods of procedure practised in the past, and to try if possible to improve upon them. One of the surest ways of doing this during such exceptional winters as the last two is to get the plants thoroughly established before severe weather sets in. Then, if they have been grown sturdily, they seem to be proof against any amount of frost. Should the weather, on the other hand, continue mild, a large percentage of such early plants will sometimes bolt. Careful cultivators, therefore, put themselves on a safe footing by making two or three sowings.

Plants raised from the later sowings are usually put into their final quarters as soon as they are large enough, which is often during October, and during a severe winter two-thirds of these late plants are killed. The practice of putting the early raised plants into their permanent quarters as soon as they are large enough is undoubtedly the best one to adopt in their case; but I hold the opinion that later plants should be treated in a different way, so that we may ensure their safety in winter, and yet have them quite as early in spring—in fact, earlier than they would be if treated in the ordinary way. A good breadth of our earliest plants have already been planted out, and the remainder will be completed in the course of a few days. Plants from the next sowing are just large enough for pricking-out, and the latest batch are now showing their first rough leaf. None of these will be planted in the open ground till spring. They will be pricked out on a warm sunny border, from 4 to 6 inches apart, according to their size, and, judging from my experience on a small scale last year, almost every plant will survive if a similar winter is experienced. These if lifted carefully with a trowel and put into their permanent quarters next February or March, as soon as the weather is favourable, will grow away unchecked till ready for use, and will follow the earliest-sown plants closely.—H. DUNKIN.

THE WEATHER OF 1892.

THE weather provides some interesting facts from time to time, as all will agree. The present year stands out as an exceptionally dry one, so far; whereas in 1891 we had, up to the present date—September 16th—ninety wet days, and consequently 168 dry days, or less than a record—viz., 0.01 of rain, this year we have registered but sixty-six days on which rain fell; the number of dry days has consequently been much greater than last year. The total quantity of rain registered last year up to the date quoted was 19.10, while this year we can reckon but 13.05. Curiously enough the month of August is noteworthy as being productive of more rain than any other month up to the present date in both years—viz., 6.69 in 1891, and 3.31 for this year. Last year this total was only topped once in any month—October—when 8.28 inch was recorded. There is but a short time left now for the average rainfall of this part to be made up, and we are considerably behind at present. Now that harvesting is all but completed, a continuous rain for forty-eight hours would do good by moistening the soil to a good depth and rendering planting of trees a much easier and safer operation for those who are about to engage in the work.

May has this year proved to be the driest month as yet; only 0.72 inch was recorded, this falling on two days only, which left us with twenty-nine dry days; and as the three last weeks were exceptionally hot vegetation was impeded, especially the planting of flower beds. The greatest amount of rain which fell in one day was 1.07 inch on August 27th; the nearest approach to this was 0.71 inch on July 16th. It will thus be seen that rain here has been scarce, but when we were experiencing such drought in May farmers in some parts of England—for instance, Lincolnshire—could scarcely get on some of their land for days together owing to its wet state; they were envying the tropical heat here, and we lamenting the surplus rain they were experiencing. The month of February in both years was very far from fulfilling the old saw of "fill dyke." Last year not a drop of rain was registered during the month; this year but 0.99 was the total.

Although we may not have had any day during the whole of the present year so hot as that registered on June 19th, 1891, when the maximum heat was 91° in the shade, we have certainly had many hot days and perhaps more regularity in the registering of hot days than in 1891. Our greatest maximum record this year was 89° on June 28th.

Taken altogether we have had warm nights, although the thermometer fell unpleasantly near freezing point on four occasions. This month on the morning of the 8th it registered but 4° above freezing on a hill 395 feet above sea level. I should think in the near valleys it was but little short of actual frost. The 15th of June and the 18th of that month this year will long be remembered by some, the thermometer falling to 28°, working sad havoc with many crops, Potatoes especially.—E. MOLYNEUX, *Bishop's Waltham*.

PENTAS CARNEA.

WHEN visiting the gardens at Parkside, Huyton, the residence of J. A. Wilcox, Esq., M.P., some well-flowered plants of this most useful and free-flowering stove plant interested me very much, and led me to wonder why it was not oftener met with in places where there is room to grow it, for it is scarcely ever out of flower, and its beautiful lilac heads will vie with many plants taking up far more room, and far harder to cultivate. Although preferring early spring for the propagation of this plant, still if cuttings of the half ripened wood can be secured now, there is no reason why a commencement should not be made. Either insert the cuttings separately in small pots in a mixture of leaf mould and sand, or place five or six in a 5-inch pot. Remove the pots to a propagating case, keeping them fairly moist but not too much so, or the cuttings will damp to a great extent. In a few weeks they will be rooted, when they may be transferred to small pots, using a mixture of loam, leaf mould, and sand. If they are kept steadily growing throughout the winter, and the points pinched out, they will by the turn of the year have grown into useful little plants, and may be removed into pots a size or two larger. In these pots a portion may be allowed to flower, and others may be kept pinched until about the end of June or beginning of July. By that time they will be ready for a shift into 8-inch pots, using for a compost three parts loam to one of leaf mould and sand, with a little charcoal added. As the plants grow and the roots begin to fill the pots, a little liquid manure will help to strengthen them, and if they can be kept in a warm frame for a month or so during the summer so much the better, as it will harden the shoots. They should be taken into the stove for the autumn and winter, by which time the grower will be rewarded with abundance of charming flowers.—R. P. R.

MALSHANGER PARK.

THIS really beautiful place is the residence of W. S. Portal, Esq., and through the kindness of Mr. Kneller, the gardener, I had the pleasure of going round the garden a few days ago. Good things are always to be found there well grown, but just now some are extra good.

In a span-roof house is the finest crop of the best-shaped Tomato I have ever seen. The variety is Sharpe's Plentiful, a greatly improved variety of Perfection. The fruit is hanging all over the house like ropes of Onions, of the most beautiful shape and colour. This house is alone worth a journey to see. Next comes a vinery, and as only one house can be devoted to Grapes, to keep up a supply as long as possible early and late varieties are grown in the same structure. Though not usually seen good together, I was surprised to see all finished and finishing well. Plenty of air and water are, I think, the secret. The next house is devoted to plants, and is just now full of really well grown Zonal Pelargoniums, which appear to be another of Mr. Kneller's specialities. Grand trusses of such varieties as Norah, Aurora Borealis, Kate Farmer, Mrs. Pearson, Queen of the Belgians, Plutarch, and Queen Matilda make a splendid display. Another small house is devoted to Cucumbers, planted with a variety of Mr. Kneller's own raising, the result of a cross between Al and Model. The plants are now a little past their best, but there is still plenty of fruit to show the excellence of the variety, which is very free, with a short neck and as straight as a gun-barrel. It will make a first-class exhibition variety. Mr. Kneller is to be congratulated on securing such an acquisition.

As these notes were only intended to be short, time will not permit of a description of everything that is well done at Malshanger. Passing to the kitchen garden we came to the exhibition Onions, and wonderfully well they looked. Mr. Kneller is a well-known expert at Onion growing, and it may not be out of place to mention that twelve Onions grown by him turned the scale at 30 lbs. His best varieties are Deverill's Ailsa Craig, Anglo-Spanish, and Rousham Park. All kinds of vegetables are well grown, annually taking first prizes at the leading shows. Last year Mr. Kneller was successful in securing a valuable gold medal for a collection of vegetables at Reading. A very fine row of Scarlet Runner Beans attracted my attention. I found that the variety was another of Mr. Kneller's careful selections, this time from Ne Plus Ultra. The young pods average nearly a foot in length. I believe the stock is likely to be distributed by Messrs. Sharpe & Co.

Beautifully kept turf walks run through the centre of the kitchen garden, on each side of which is a fine collection of herbaceous plants and annuals for cutting purposes. Very conspicuous are large plants of the Globe Thistles, *Echinops Ritro* and *ruthenicus*, *Achillea*, *Eupatorium*, and Golden Rods. A description of the charming flower garden surrounding the mansion, with the many fine views, must be left over for a future occasion.—G. TRINDER, *Dogmersfield*.

EVENTS OF THE WEEK.—The ensuing week will be one of the quietest of the year. There are no shows of any importance announced. A meeting of the Floral Committee of the National Chrysanthemum Society takes place on September 28th. Auction sales of bulbs and Orchids will be conducted during the week; for particulars see advertisements on the second page.

— **THE WEATHER IN LONDON.**—A fine week has to be recorded, the weather having been uniformly dry, warm, and fine during the past seven days. Harvesting, fruit gathering, Potato lifting, and other operations have proceeded with little or no check, in which there is cause for thankfulness. Circumstances now indicate a change. The barometer shows a little depression, and the wind, which is south-westerly to westerly, is light and variable. At the time of going to press the weather is showery, warm, and close.

— **UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.**—Mr. John Fraser of Lea Bridge will preside at the annual dinner of this Society, which takes place at the Cannon Street Hotel on Wednesday, October 6th, at 6 P.M.

— **FRENCH HORTICULTURE AT THE WORLD'S FAIR.**—The French Commission will send to the World's Fair to superintend the horticultural and floricultural work in the French section M. Le Fevre, the Superintendent and head gardener for the City of Paris, who has charge of the gardens in the Bois de Boulogne. M. Le Fevre was in charge of the gardens around the Trocadero at the Paris Exhibition in 1889. M. André will prepare the plans.

— **VERONICA LONGIFOLIA SUBSESSILIS.**—This is perhaps the finest of all the Veronicas. Flowering late as it does in the summer it is very valuable, prolonging the display when the bulk of the family have faded. The colour is a rich purple blue. The flower stalks grow from 2 feet to 3 feet high, and are freely clothed with large dark green leaves, which enhances its appearance considerably. No collection of herbaceous plants is complete without this Veronica.—E. M.

— **PEACH GROSSE MIGNONNE.**—This is one of the best varieties for outdoor culture. It is of free growth, not subject to insects, mildew, or any ills which yearly befall some open air grown Peaches. On a south wall the fruit assumes an exceptionally high colour when the leaves are put on one side to admit of the sun shining full on the fruit. The flavour is good, perhaps the best of any variety out of doors. We have a tree covering an 8 feet high wall for 30 feet, which is bearing 260 fruits, very even in size. The tree is in a most promising condition for next year also, the buds appearing to be plumping up quite full.—E. M.

— **EXHIBITION OF POTATOES AT EARL'S COURT.**—A schedule has been forwarded to us of a great Potato Show, to be held in connection with the display of hardy fruit at the International Horticultural Exhibition, Earl's Court, on Wednesday, Thursday, and Friday, October 5th, 6th, and 7th. Seventeen classes are provided, thirteen of which are restricted to varieties in commerce, and four to seedling varieties not yet sent out. Many of the prizes are special contributions; for instance, in the first, which is for twelve dishes, nine tubers of each variety, Messrs. Sutton & Sons offer prizes of £6, £4 10s., £3 3s., £2 2s., and £1 1s. They also offer prizes of £5, £4, £3, £2, and £1 for nine dishes; and a set of the same value for six dishes. The Lord Mayor offers prizes of £2, £1 10s., £1, and 10s. 6d. for three dishes of white rounds; and there are many others, while the Executive also give many prizes. Besides the money prizes, a silver medal will be given for the best dish of Potatoes in the whole of the classes, and a gold medal for the most meritorious collection of Potatoes. Schedules are now ready, and can be had from the Secretary of the International Horticultural Exhibition, or from Mr. P. McKinlay, 24, Upper Thames Street, London, E.C. The latter has long taken a deep interest in the noble tuber, and it is pleasing to hear that he will manage the Exhibition. In so good a Potato year as this we may reasonably expect a very fine display.

— **TREE OF LIFE.**—Can any of your correspondents tell me the botanical name of the Tree of Life from Nova Scotia, and what treatment it requires?—W. J. J.

— **A CHANGE OF CHARGE.**—Mr. Henry Purser, who has had charge of the gardens at Ravenhill, Rugeley, Lord Zouche's Staffordshire residence, will in future superintend those at Parham Park, Pulborough, the same nobleman's Sussex seat.

— **SHOW SCHEDULES.**—The schedules of the Chrysanthemum Exhibition and Floral Fête, and of the spring Show of the Ancient Society of York Florists, have come to hand. The former will be held on November 16th, 17th, and 18th, the latter on April 26th and 27th, 1893. Spalding Chrysanthemum Show is fixed for November 10th and 11th; schedules are now ready.

— **THE FIRST FROST.**—There was sufficient frost in this part of Suffolk on the morning of September 18th to cut off the Vegetable Marrows and to touch Dahlias and Heliotropes. As more than half of our Vegetable Marrows were cut off on June 15th the summer of 1892 has been indeed a short one. The Dahlias were first touched last year on October 29th.—W. R. RAILLEM.

— **FROST AT BOURNEMOUTH.**—This locality was visited by a very severe frost on Saturday night, which has cut down Dahlias, Vegetable Marrows, and Scarlet Runners; but happily we in the centre of Bournemouth have escaped with only a slight touch of it. We have been having beautiful weather, and flowers were looking up after the late heavy rains and wind; it seems a pity to have them cut down suddenly.—J. B. STEVENSON.

— **SALE OF A SEEDLING ROSE.**—Messrs. Alex. Dickson & Sons of Newtownards have sold their gold medal seedling Rose, Mrs. W. J. Grant, to an American gentleman, who, upon seeing it, would not be said "Nay." I compliment him upon his good taste, as this Rose, which is a seedling from La France, is a magnificent one, perfect in shape, delightful in colour, deliciously perfumed, and one of the freest bloomers I ever saw.—M.

— **RETINOSPORA PLUMOSA.**—At the Swiss Nursery, Farnham, there are two very fine specimens of this refined-looking and very handsome Conifer, which are so good that, to quote Mr. Mortimer's words, "they have sold hundreds of young ones." The soil is essentially what may be called common land, not very deep, and originally a barren heath. Draining and trenching, however, have done wonders for it, with the result that what a few years ago seemed incapable of growing a common weed well now grows even show Dahlias in remarkably fine condition. These Retinosporas are each about 12 feet in height, and some 25 feet in circumference. They are of perfect form, and without a flaw, not a single rusty branch being found on them. This is probably the result of congenial soil. In any case it suits all kinds of Conifers well, especially Retinosporas.—D.

— **THE HOP CROP.**—A very distressing sight indeed was the general appearance of the Hop plants about Farnham last week. The work of picking should, under ordinary conditions, have been in full swing, but in extensive gardens in all directions there were seen immense quantities of the plants still standing untouched because so blackened by cold or winds or blight, or from all causes combined. No words can fully convey what the eye could thus see. In some places one-half the poles had been pulled, in others not more than one-third, these having been taken out here and there. In some gardens the crop was so clean a complete clearance had been made, but these were few. In others there did not seem to be one pole worth gathering from. In only one garden, and that a low-lying and well-sheltered one, did I see a really fair, clean crop, and that was of a late variety. It is all very well to talk about the uncertainty of fruit culture, but it is a bad season that gives no produce, whilst fruit cannot be of such costly culture as Hops are. Still further, even if the trees are fruitless, it is rare that they are not benefiting by the rest from production thus afforded. A bad season for the Hop crop is equally a bad one for the plants. I should prefer to see a sparse crop of Apples, Pears, or Plums at any time than such a one of Hops as this year affords. Having regard to the amount of filthy manure, all sorts of disgusting compounds, which Hops are dressed with, it is no matter for wonder that sometimes the plants suffer from epidemics. It is a wonder that humanity does not suffer also in the same way. Happily, not only is fruit culture exempt from those abominations, but the trees would hardly appreciate such treatment.—A. D.

— **TIGRIDIAS.**—Tigridias are a most gorgeous class of bulbous plants, and are of exceptional beauty. They are the most attractive when they unfold in the morning, but as the sun sets the flowers wither. As new blooms are produced almost daily a continuance is maintained for a considerable time. For the front of the herbaceous border there are few plants that can excel them in consequence of their peculiar shape and remarkable beauty.—GEO. PARRANT.

— **LYSIMACHIA CLETHROIDES.**—This Loosestrife is rather an uncommon plant in the herbaceous border, though not very rare. The peculiar manner in which the extreme point of its flower droops while expanding renders it interesting. As expansion takes place the flower spike assumes an erect habit. The flower is of the same form as a Clethra, hence its name. The plant blooms during August. The height altogether is a yard under good cultivation. We have it growing at the back of the rockery, the heavy soil suiting it well. It is of a creeping habit under the surface, where its roots run freely, therefore no trouble to propagate it is experienced.—E. M.

— **TOMATOES GREEN WHEN RIPE.**—I send a tin box containing three fruits of a Tomato, a sport from Sutton's Golden Nugget, in every way the same, but green when ripe. As I have neither seen nor heard of a green-fruited Tomato I thought you might be interested. I sent a specimen to Messrs. Sutton & Sons. They thought it interesting, but that the public generally would not appreciate it on account of its colour. I lost a few of the first fruits owing to their colour. Although ripe they were still green, and no doubt the public being used to bright fruited Tomatoes would think them unripe.—A. DUNCAN. [The fruits are as you say ripe but quite green. Probably there are some local conditions accounting for the greenness. We agree with Messrs. Sutton that the fruit would not be generally appreciated, although the flavour is good.]

— **POLYGONUM BRUNONIS.**—I have never seen this hardy perennial grow or flower better than it has done this season, and it would seem as if it could scarcely have too much moisture when well established. We have at the present time a grand clump of it in flower; there are hundreds of spikes, the older being of a pleasing deep rose colour, whilst the younger are many shades lighter, and they give the plant a very quaint appearance. For decorative purposes it is most useful, the slender spikes being well adapted for relieving heavy masses of flower. With us it is of the easiest culture. Planted in a border having an east aspect, in fairly good garden soil, 15 inches from the solid clay, and receiving a good top-dressing of decayed manure during the winter time, it has grown and flowered remarkably well for a number of years, and is now in excellent health.—R. P. R.

— **NEMESIA STRUMOSA SUTTONI.**—It will be remembered that this strikingly beautiful new annual, a native of South Africa, recently received a first-class certificate from the Royal Horticultural Society, when exhibited by Messrs. Sutton & Sons, Reading. Nearly the whole stock of seed they had was placed in the hands of Mr. Mortimer of Farnham to grow, and on his healthy soil it has done admirably, and is producing a fine crop of seed. Treated as a tender annual, the seed being sown under glass in March, and the seedlings transplanted to the open ground at the end of May, they soon bloom profusely, and continue to do so up to the end of September. The habit of the plant is not unlike that of the yellow Erysimum, but the flowers are much larger, the colours are extremely beautiful, and very varied. This annual must soon become extremely popular, for it is easily grown, and for the size of its blooms has no rival in beauty as well as in variety of colouring.—D.

— **CARNATIONS AS ANNUALS—A NEW RACE.**—Mr. Herbert, of Messrs. Thomson & Co., last autumn crossed one plant of a Marguerite Carnation with pollen from Robert Houlgrave, scarlet bizarre, and sowed the seed in February of this year. Eight plants, the result, are now flowering. One, a self scarlet, of which I enclose petals, is a very great improvement, the flower covering the accompanying card without dressing. I look for a new race of Carnations from this strain, charming well-shaped pot plants, easily grown in 48-pots from seed sown in February, and now in bloom. The Marguerites are not tall growers, and have an erect habit, bearing the flowers on stiff stems. I will send you fuller notes shortly, as two or three very promising seedlings are only just opening their buds.—W. D. [The petals are of great size and substance. We shall hope to hear more of this series of crosses, as they are likely to give us a very useful class of plants for treatment as annuals.]

— **DEATH OF A NORTHUMBRIAN GARDENER.**—It is with regret that we announce the death of Mr. James T. Pringle, of Benton Hall, Northumberland, which took place suddenly on the 8th inst., at the early age of forty-two. The deceased had filled the position of head gardener at Benton for the past thirteen years with every credit and success. He was a devoted gardener in every branch, but his favourite flower was the Chrysanthemum, which he cultivated with skill, and gained many prizes. He has left a collection of fine healthy plants, and had he lived they would have done him credit at the forthcoming shows. He was a very kind hearted and genial man. His untimely end will be read of with regret by a large circle of gardening friends, by whom he was much respected.

— **STATICE LIMONIUM VAR. SMITHI.**—Although the Sea Lavender, *S. Limonium*, is common enough on some parts of the English and Scotch coast lines, and is extremely pretty, yet its cultivated varieties far exceed it as ornamental garden plants. The variety *Smithi* has stout radical leaves, often a foot long, narrowed into a stalk at the base; very dark green. The small purplish flowers are produced on much-branched spreading corymbose panicles, growing 2 to 3 feet high. A plant 18 inches across will produce twelve to eighteen spikes of flowers, and these if lightly staked out will form a fine head of flower 3 to 4 feet through, making a splendid plant for a large rockery. Amongst cut flowers few last so long as *S. L. Smithi*. A large plant is flowering on the rockery at Chiswick, and some may be seen at Kew.—C. K.

— **BOURNEMOUTH AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.**—There was a good attendance of members of this Society at the last meeting to hear a paper on Vegetables for Exhibition, which was read by Mr. G. Garner, gardener, Amberwood, Christchurch. Mr. Garner dealt principally with the varieties found on the exhibition table, and gave many practical hints on how to grow and show them. He was accorded a hearty vote of thanks for his excellent paper, which was rendered more interesting by an exhibition of six varieties of vegetables, a good display being made, and first and second class certificates awarded. Mr. G. Shave, Higham, occupied the chair, and a hearty vote of thanks was given to him at the close of the meeting.

— **PINE APPLES FOR PROFIT.**—English-grown Pine Apples have been in demand this season, and the prices, for the first time during many years, have proved remunerative to the grower; in fact, this fruit has been the most profitable of any other grown for sale in a large establishment from which the produce is disposed of in the markets. The supply has been inadequate to the demand, several tempting offers at fancy prices having to be refused in consequence of six large houses, formerly devoted to Pine Apple culture, being converted into vineries and Peach houses, the produce of which has not been half as profitable as that from the six structures still employed for growing Pines. It is pleasing to record a change in public taste for home-grown fruit, which is not only more taking in appearance, but vastly superior in flavour to that imported—G. A.

— **FRUIT CULTIVATION IN THE BAHAMAS.**—In his latest report to the Colonial Office, the Governor, Sir Ambrose Shea, states that the Bahamas offer great inducements for fruit growing. Pine Apples are at present the principal crop, but the particular description of land required for their culture is a limited quantity. Of late years the growth has been much improved by the use of fertilisers, with a considerable increase of quantity. The crop yields large profits. At 2d. each an acre of Pine Apples returns £40 to £45, and though precarious from its perishable nature, while such results are possible, it will continue to be an attractive pursuit. The Governor does not, however, desire to see it extended, as the sole means of the cultivators, beyond its present limits; for the increasing competition of Cuba and Jamaica is a further element of insecurity in the future of this industry. In Oranges a good business might be done if the accounts of Florida enterprise in this fruit are a fair criterion. At present the Oranges of the Bahamas are roughly handled, being generally shipped in bulk in vessels' holds, and often without compartments. The fruit is equal to any in the world, and when for the most part it receives no attention the result of careful cultivation could not fail to be remunerative. The facilities for production are fully up to those in Florida, and the colony is entirely free from all risks of frost, which so often blights the Florida crop. The success of the industry in this colony would be partial, however, until the proper system of packing were adopted to insure delivery at market in good condition. With this point secured and the advantage of steam

communication, which is fast becoming available, Orange-growing should be a profitable source of employment. Tomatoes are grown to a moderate extent, but the production might be largely increased, and when more intelligent enterprise from abroad, of which the prospect is now encouraging, is brought to bear on the various opportunities for steady money-making in the colony, its history will become distinguished for more than the transformation its famous fibre is effecting. It is to be regretted, the Governor remarks, that of the many young Englishmen who embarked in Orange-growing in Florida, with chequered results, and of those also who sought their fortunes in South America, some at least had not found their way to this colony, where energy and thrift, applied to the varied resources, can hardly fail to be rewarded, and where personal rights and property are under the protection of British laws and administration, a consideration to which the history of the southern republics during the past two or three years has given striking significance.

— **DATURAS.**—It is almost surprising that these plants are not more largely grown, considering how easy they are to cultivate and how useful they are for general decorative purposes when well managed. They thrive well against pillars or planted out in beds or borders of large conservatories, and may be grown either as large bushes or dwarf trees. If they are desired to be grown in moderate sized houses the best plan to adopt is to grow them as standards. Cuttings taken from the old wood, when they have grown 5 or 6 inches in length, in the spring root freely; these should be grown till they have attained a height of from 4 to 5 feet, when the main stem should be stopped, the object being to encourage branches to break out for the purpose of forming a head, which they will very quickly do. Three or more of the strongest shoots should be selected, and should be pruned back annually to where the leading branches originate. The best time to prune is in the autumn, when the plants are at rest.—G. P.

— **HELIANTHUS SOLEIL D'OR.**—This is undoubtedly an improvement upon *H. communis* fl.-pl., of which it is a variety. The flowers are more freely produced, the florets more erect, and there are not so many of them in each flower as in the type. The colour is brighter, too, which renders it more conspicuous in the border. This variety forms a good contrast to *Dahlia Glare* of the Garden when planted with it; indeed, it can be employed in a variety of ways in flower garden arrangements. We have it in a mass in the centre of a bed, and for hiding a low brick wall on the northern side it succeeds capitally. Mixed with single and Cactus Dahlias at the back of a border in front of a Holly hedge, it is a good feature; in fact, it is amenable to any reasonable treatment. The best way to secure a stock of plants for summer use is to lift the roots in the autumn, laying them in in some sheltered place, say at the foot of a south wall, in light sandy soil, dividing them in the spring, planting them in a temporary turf pit in good soil. By this means the crowns escape the attacks of slugs, which they are subjected to if they remain in the border all the winter.—E. M.

— **THE IMPURITIES OF TOWN AIR.**—This subject is one in which town and suburban horticulturists cannot fail to take considerable interest. Dr. G. H. Bailey, of Manchester, is reported in Symons's "Meteorological Magazine" to have said that during the past twelve months the Air Analysis Committee of Manchester, in conjunction with the Royal Horticultural Society, had been engaged on the analysis of the air of large towns. Much information as to the carbonic acid in the air having been collected by previous observers it had been thought desirable to devote especial attention to sulphurous acid and organic matter. Since the object was not merely to collect data, but to lay the foundations of what may be termed chemical meteorology, the atmospheric conditions prevailing at the time of the observation had been noted. From the results of several hundreds of analyses carefully conducted in London, Manchester, and Liverpool, the following conclusions had been drawn:—(1) That in clear breezy weather the amount of sulphurous acid is less than 1 milligramme per 100 cubic feet of air; (2) that in anticyclonic periods it rises very considerably, and in times of fogs, maxima of 34 and 50 milligrammes have been recorded for the worst districts of Manchester and London respectively; (3) that wherever an open space or a less densely populated area occurs, there is a very marked diminution of the amount of impurities in the air; (4) that an increase in the amount of sulphurous acid is accompanied by at least as large an increase in the amount of organic impurities in the air; and (5) that smoke, promoting as it does the formation of fog, and preventing free diffusion into the upper stratum of air, must be regarded as the principal cause of the impure state of the atmosphere in large towns.

— **THE CAUSE OF APRICOT BRANCHES DYING.**—I do not always look over the *Journal* directly it comes in (though I feel I ought to do so), and it happens that I have not noted till to-day the report of the Conference on Apricots and Plums, published in the issue of September 1st. Some conversation took place relative to the dying off of Apricot branches, and explanations were given with regard to this. I may remind you that we had sent on some years ago specimens of the Apricot, the wood of which had been mined by the caterpillars of *Sesia myopæformis*, well known as a foe of the Apple and Pear, specially the latter, and living both in the trunk and boughs. Previous to that the insect had not been noticed on the Apricot. I expect it does occasionally infest it, and the instance recorded was not a solitary one. This, then, would be another possible cause for the dying off of the branches of Apricots: the signs of the presence of the larvæ might be overlooked. I should not think, however, the insect would be found on Apricots under glass.—ENTOMOLOGIST.

— **DURHAM FLORAL SOCIETY.**—The twentieth annual Exhibition of the above Society was held in the New Markets and Town Hall of the ancient city on September 13th and 14th. The Show was a good one all round, competition being keen, and the entries numerous. This Society is making steady progress. It is under the patronage of the principal gentry of the district, and has a good working Committee. Unfortunately the Secretary was indisposed during the Show time, but a good substitute was found in G. H. Procter, Esq. Plants in pots, open to all, brought forth some good competition in the various classes. Some fine specimen *Ericas* were exhibited. The table decorations were superb; the bouquets and sprays were grand. The same may be said generally of the principal classes for cut flowers. Fruit was excellent; so close were those entered for the principal prizes that the judges were compelled to award equal firsts. Grapes were good and well coloured, while Peaches, Nectarines, Apples, Pears, and other fruits were fully up to the standard. Certainly they can grow good vegetables in the district, for those sent both by cottagers, amateurs, and professional gardeners in the district were superb, and they were also well staged, reflecting great credit upon the numerous competitors. The Show was well attended, and we are able to record a satisfactory meeting of this Society for 1892.

— **ONIONS AT BANBURY.**—The annual Exhibition of Onions at Mr. Deverill's Royal Seed Stores, Banbury, in competition for the handsome prizes offered by him, was held on the 15th and 16th inst., and a remarkable show it was, all the stocks being well represented by exceptionally fine bulbs. Over ninety dishes were staged, which comprised considerably over 1000 bulbs, twenty specimens being required in two classes. Very many dishes that did not gain a prize would have been an easy first at many of our leading shows. Class 1 was for the best dish of twelve bulbs of the following varieties:—Rousham Park, Anglo-Spanish, Royal Jubilee, Lord Keeper or Advancer. The first prize was easily won by Mr. Kneller, gardener to W. S. Portal, Esq., Malshanger Park, Basingstoke, with a very fine lot of Anglo-Spanish, weighing 22 lbs.—an unusual weight for this variety; several of the bulbs measured more than 18 inches in circumference. This dish also secured the gold medal offered for the best dish of Onions in Classes 1 and 2, beating Mr. Bowerman's larger and heavier dish of Ailsa Craig in Class 2, which weighed 4 lbs. heavier, but were not so good in quality, needing more time. Mr. Wilkins, gardener to Lady Theodore Guest, was second with Rousham Park, weighing 18 lbs. Third, Mr. Copp, gardener to J. S. W. S. Drax, Esq., Holnest Park, Sherborne, Dorset, with Lord Keeper, weighing 18 lbs. Mr. Pope, Highclere Castle Gardens, Newbury, was fourth with the same variety, weighing 17½ lbs. Class 2 included Deverill's Ailsa Craig, Deverill's Cocoa Nut or Original Excelsior. Mr. Bowerman, gardener to C. Hoare, Esq., Hackwood Park, Basingstoke, was an easy first, showing Ailsa Craig, weighing 26 lbs. Mr. Wilkins was second with the same variety, weighing 23½ lbs., and Mr. Pope third, also showing Ailsa Craig. Mr. Lye was awarded a special for a very pretty dish of Original Excelsior, weighing 20 lbs., a very clean, bright-looking Onion. Class 3 was for twenty specimens of that good-keeping Onion Deverill's Improved Wroxton. Mr. Wilkins was first with a good even dish, weighing 26½ lbs., Mr. Pope second, his exhibits weighing 23 lbs., and Mr. Lye third. Class 4 was provided for cottagers, allotment holders, and mechanics, the Onions to be selected from Deverill's Main Crop, Deverill's Improved Wroxton, or Improved White Spanish. Mr. Moss of Hackwood was first with Main Crop, Mr. Winfield of Shutford second with White Spanish, and Mr. Bliss, Church Lane, Banbury third with the same variety.—VISITOR.

JOTTINGS ABOUT LONDON PARKS.

REGENT'S PARK.

It has been said that the bedding in Regent's Park is hardly up to its reputation this year, but my experience hardly corroborates this assertion. The second week in September is not, as a rule, the time of year to see summer flower gardening at its best, but if the bedding in this Park has been better than it is now, the display must have been wonderful. Some delightful arrangements are to be seen there. The plants in the whole of the beds seem to have grown too with greater vigour than in many other parks, and the majority of them at the time of my visit were flowering profusely. Tuberous Begonias are a decided success; in none of the parks are they so good this year as there. Several beds and narrow borders are filled with them, and the plants have not only made remarkable growth, but are flowering exceedingly well. In several beds they are associated with *Alyssum variegatum*, the light foliage of the

shape, about 12 feet in diameter. There is a vase filled with drooping pink Ivy-leaved Pelargoniums in the centre. Around the vase and over the whole surface of the bed small Palms and Golden Treasure Fuchsias are dotted, the groundwork being filled in with *Lobelia pumila magnifica*. The latter is a mass of bloom and blends beautifully with the other plants. An edging of *Echeverias* completes the arrangement, which in every respect is unique.

The beds of Cockscombs and *Celosia plumosa* are also excellent, indeed it is seldom that these plants are seen to such advantage in the open air. Many of them are not only fine specimens as regards size, but most brilliant in colour. For producing an effect in the flower garden during the autumn they are obviously admirably adapted, and might with advantage be similarly used in private establishments. Besides being used in beds there are some bold masses of Cockscombs in prominent positions on the borders, where they produce a remarkably fine display. It would seem that an effort to produce an autumn

FIG. 36.—MESSRS. CARTERS' POTATO DISEASE EXPERIMENTS.

RIGHT SIDE, DRESSED WITH *BOUILLIE BORDELAISE*, UNINJURED; LEFT SIDE, NOT DRESSED, DESTROYED BY THE DISEASE.

latter making a charming combination with the brilliant flowers of the Begonias.

In addition to the large beds of Pelargoniums there are some charming arrangements of a less vivid nature. Heliotrope is used with good effect, some beds of it being very fine, and the majority of these are edged with *Cineraria maritima*. The white foliage of the latter harmonises well with the dark green leaves and purplish flowers of the Heliotrope. A few similar beds would have a good effect in a private garden. Carnations, too, are a pleasing feature here, a bed of Raby Castle making a charming effect. This is a lovely pink Carnation, and even at this late period the plants are laden with bloom. Notice of this fact should be taken, inasmuch as it may help to remove the impression that Carnations are unsuited for bedding purposes owing to their comparatively short period of flowering. The plants alluded to have apparently been in bloom since July, and appear as if they will continue flowering long after the tender things are blackened by frost. Many other hardy plants are also used here for bedding purposes. Several beds are planted with *Campanula carpatia*, Palms and *Anthericum variegatum* being dotted amidst the Campanula, and edged with *Mesembryanthemum cordifolium variegatum*. The result is a delightful effect. Another pretty arrangement is deserving of notice. In this case the bed is circular in

show of bloom is made in Regent's Park, and not without success. A bed filled with yellow Chrysanthemums, edged with Mrs. Pollock Pelargonium and *Gazania splendens*, is very showy, and the same may be said of another planted with orange and crimson Celosias and *Dactylis glomerata marginata*. A noticeable feature is that many of these beds are edged with London Pride (*Saxifraga umbrosa*). Zinnias and Stocks are also employed in the beds with good effect.

Fuchsias are very fine. There are many large beds planted with them, and large specimens are dotted on the grass. In each case the plants are laden with bloom, and make a grand display. Vases filled with foliage and flowering plants are also deserving of notice. The borders are also exceedingly showy just now, there being some grand masses of Asters, Helianthus, Gladioli, *Sedum spectabile* early flowering Chrysanthemums, Dahlias, and other autumn-blooming plants. The results of planting in large groups may be seen to advantage, and the system is well worth imitating in private gardens.

DULWICH PARK.

Notwithstanding the new appearance which must necessarily be a prominent characteristic of a recently laid out open space, Dulwich Park can justly claim to be one of the most beautiful lungs

of South London. There is a charm about the whole place quite its own. Bedding in the generally accepted term is not a strong feature so far as quantity is concerned, but what there is is well done. Many of the beds, moreover, are models of judicious contrasts and pleasing harmonies.

Mixed beds are particularly good. Near the entrance from Dulwich village there is a singularly effective bed. This is planted with crimson tuberous Begonias and white Violas, amongst which are fine specimens of the variegated Maize. A ring of *Iresine Lindenii* and another of *Mesembryanthemum cordifolium variegatum* complete the arrangement. It is one of the most beautiful beds I have seen this season. Near to the last named a mass of variegated *Abutilons*, with which Fuchsias and blue Violas are mixed, make a fine display. This bed is edged with Golden Treasure Fuchsia, an attractive yellow-leaved dwarf growing variety, admirably adapted for edging purposes, and it seems to be a favourite in the parks. Another bed filled with pink Ivy-leaved Pelargoniums and yellow Violas, around which rows of *Iresine Lindenii* and *Cineraria maritima* are planted, is most effective, and the same may be said of a mixture of Fuchsias, Petunias, and Lilliums. The Fuchsias in the latter instance are full of flower and in harmony with the Petunias. Rows of *Iresine* and Golden Treasure Fuchsia complete the bed.

In addition to those mentioned there are the usual masses of Pelargoniums, and amongst these Violas are planted with good effect. As an example, a bed of white variegated Pelargoniums and blue Violas shows up well, and so do the white Violas with pink and scarlet Pelargoniums. These mixtures are worthy of imitation. The few examples of carpet bedding are also deserving of notice. They are simple in design—a good feature, by the way—and charmingly arranged, the foliage being particularly bright and effective. Clumps of foliage plants, such as *Acacia lophantha*, Cannas, and Eucalyptus planted on the grass are likewise effective and a distinct feature.

The borders in this park are very fine. There are not merely two or three, but a large number of them, such as may generally be found on the margins of newly formed clumps of shrubs, and all of them are now gay with autumn flowers. The huge masses of perennial Sunflowers with their bright yellow flowers are most effective, while scarcely less can be said of the fine clumps of *Nicotiana glauca*. Some groups of *Hyacinthus candicans* planted among dwarf Rhododendrons are particularly effective, as also are colonies of *Gladioli* amidst Roses. In some borders there are many fine China Roses, and the whole of these are at the present time flowering most profusely. They are very effective, and afford ample proof of their adaptability for general decorative purposes. Would that there were many such similar clumps of these beautiful Roses in every private as well as public flower garden. They are among the first to bloom, and certainly the last, often in mild autumns continuing to produce their brilliant crimson, pink, and white flowers until November has set in. It is almost impossible to over-estimate the value of these Roses for garden decoration, and as seen now in Dulwich Park they are worthy of all that can be said in their favour.

Still another feature remains to be noticed—namely, the rockeries. These are numerous, and are well arranged. The second week in September is not, as a rule, the best time to see alpine and other rock plants, inasmuch as the majority of them bloom in spring, but it is refreshing to turn from the glare of the plants in the other beds to the green masses of Sedums and Saxifragas on the rockeries. For developing this feature Mr. Moorman, the able superintendent, deserves the congratulations of all lovers of hardy flowers. It is gratifying to see such onward strides, and it is to be hoped that even greater progress in this phase of flower gardening will be made in public parks and gardens. The eye soon tires of the glare of colour produced by masses of Pelargoniums and similar flowers, as well as of the stereotyped carpet patterns; but as regards the delightful greenery of the ever charming rockery one never grows wearied.—C. C.

BEGONIAS AT FOREST HILL.

DEVOID of all capacity to appreciate beauty must be the man who could gaze, not merely for the first but for the fiftieth time, upon the truly grand show of Begonias now to be seen in full bloom at Forest Hill without admiration. If Messrs. J. Laing & Sons have obtained a world wide reputation for these flowers, at least they have worked hard to deserve it. Where else in the kingdom can be seen a more beautiful sight than is presented in some probably quarter of a million of seedling plants in rich bloom, covering fully 2 acres of ground, and growing just as freely and luxuriantly as Cabbages? Great as is the area of ground, still is it needful to crowd the plants, for they are in rows about 12 inches apart, and are about 7 inches asunder in the rows. Even in mentioning that there are 2 acres of ground planted with Begonias it is hard to convey an adequate conception of the beautiful show made. Really it is one of those sights which should be seen to be realised. From the main road the beds run parallel with the chief pathway for a length of 180 yards. There are twenty-two of these beds, each containing seven rows of plants. The one near the nursery path is a mixture, then comes one of rose tints, then two of orange scarlet, next one of golden bronze, then come two yellows, following are one red and two white, then single beds of crimson, salmon or apricot; yellow, and pink, and seven other beds planted half of one colour lengthwise and half of another. Beyond these run a large number of short cross beds, including myriads of fine doubles.

In several houses there is a splendid show of plants, so gloriously beautiful and of such rich and varied colours, the flowers, too, in many cases of such enormous size, that one realises after all how poorly even may the finest of gold medal groups convey what a visit to Forest Hill displays.

One of the most remarkable features of the myriads of seedlings is found in the high average of constancy to colour they show. Some beds seem hardly to have a diverse colour in them. There is more variety in the golden, bronze, and yellow hues, but still all pertain to the section. In the matter of show the richest or most striking effects are got from the white, pink, or rose, scarlet, and crimson hues, especially the singles; indeed the doubles seem better fitted for house or pot culture than for exposure to rough weather; still, they are beautiful apparently in all weathers. These have this season given a fine lot of yellows. Seedlings of doubles reproduce about 50 per cent. doubles, and all singles are thrown away. In both sections second year tubers make the best bedding plants, and give fine sturdy plants, but are still better the third year.

It must not be concluded that if Messrs. Laing can thus raise hundreds of thousands of seedlings anyone can raise even a few. All may try, but all are wiser if they will also purchase selected tubers, especially if they wish to bed them in colours. Those who wish to see this Forest Hill feast of Begonias should lose no time in carrying out their intention.—A. D.

WE had anticipated the advice given in our correspondent's communication by visiting Forest Hill before it reached us, and agree with him that a more brilliant and wonderful display of floral beauty cannot be found than is now to be seen at Messrs. Laing's nursery, which, it may be mentioned, is best reached from Catford Bridge station, though it is not more than a mile from Forest Hill. In the article, "Progress in Begonias," a few weeks ago, the latest developments in quality of flower and habit of plant were so fully dealt with that it only remains to make a brief study of the plants as turned to bedding purposes, and see how their points of merit tell in the open air. Beyond doubt there is much ground for admiration. Apart from their intrinsic beauty, it cannot but be noted with pleasure how well qualified the plants are to hold their own, and give fine effects, unsupported by companions of any other class. This is not a question of quantity. Were there but a fraction of the 400,000 plants now bedded out in the Stanstead Park nurseries, the quality indicated would be still observable. It is not suggested as desirable that this feature should be pushed to an extreme consummation and flower gardens adorned with Begonias alone, but they may always form a feature in beds to themselves if so desired. There is a luxuriance of growth about them that in most plants would be accompanied by imperfect blooming, but they produce flowers both abundantly and of high-class quality, imparting rich, bold, and satisfying effects.

That it would be unwise to rely on seedling plants altogether for a summer display in the flower garden has been well proved this season, for they have been somewhat late in getting into the best condition. Possibly it has been somewhat too dry for them, and a little more moisture would have insured their coming into full bloom earlier. Now that they are at their best, however, there is no gainsaying their exceptional beauty. Their dwarf growth and abundant foliage prevent any suspicion of gaudiness, even in the brilliant scarlets, glowing crimsons, and bright yellows that abound. The close mantle of green acts as an admirable foil, and they are not so near the eye as to stare one out of countenance. The scarlets are undoubtedly the most effective. "A. D.'s" remarks preclude the necessity of any indication of the range of colour observable, or of the method and scale of planting, but a few varieties may be noticed. Of scarlets two of the best are Lord Hillingdon and J. W. Wilkinson, the former in particular, a light scarlet inclining to orange, being a most vivid and striking variety. As a bedding Begonia it would be very hard to excel it. Of the crimsons H. M. Stanley and Sir Thomas Paine are the best. The former is very conspicuous, the long lines of richly coloured flowers being quite imposing. Mrs. Milner, a carmine with white centre, is also effective. The rose and pink shades hardly tell so well, but they are very beautiful nevertheless, and will bear close individual inspection. Gigantea is very fine indeed. Lady Pigott is of a distinct salmon shade, and Duchess of Leinster a light yellowish orange, both being excellent varieties. Of whites Lady Scott is perhaps the pick, the flowers being substantial, well thrown up, and very pure.

When it is remembered that all the plants bedded out on this enormous scale are seedlings raised in January this year it will be perceived what an invaluable plant we have in the Tuberous Begonia as a bedding plant. It may be treated as annual, and what other annual is there to compare with it? Beautiful as it is there is no doubt whatever that it will be still further improved. Messrs. Laing & Son have men constantly at work amongst the plants marking the best varieties, and if these are examined it will be found that they have stouter flower stems than their fellows, and often larger, smoother, more rounded flowers as well. The latter points are desirable, but the first is the most important. After all that has been done there is still room for improvement in the direction of longer, stiffer, and stronger flower stems. We have no doubt that it will come. Messrs. Laing have so well proved their capacity that the fact of their being alive to a requirement may be taken as a sufficient assurance that sooner or later it will be provided.

AN OLD GROWER ON THE EARLY VARIETIES.

IN our report of the Show of early Chrysanthemums at Leicester last week we referred to the paper on this valuable section read by Mr. W. K. Woodcock of Barkby Road, Syston, an old and experienced grower, and we now have pleasure in publishing it. After a few appropriate introductory remarks the author proceeded as follows:—In a paper read by Mr. W. Piercy before the National Chrysanthemum Society on September 11th, 1889, it is recorded that as far back as 1817 the London Horticultural Society offered a medal for early flowering Chrysanthemums, with what success is not now known, but the fact of such a medal being offered points to the probability that some were even then known and grown. It is also stated that Mr. Broome, then of the Temple Gardens, and one of the foremost cultivators, published in 1858 a little book upon the Chrysanthemum, in which he mentions thirteen sorts, amongst them being two which are still cultivated—viz., Dr. Bois Duval (which has two other names, Little Bob and Scarlet Gem) and Frederick Pélé, the latter still being one of the very best in its colour.

One of the first to take up their cultivation in earnest was the late Mr. Alfred Taylor of Fencote, Bedale, Yorkshire. In the "Gardeners' Magazine" for December 6th, 1873, he gives a report of the trial culture of a number of varieties, more or less early, and states that six varieties proved quite a success—viz., Jardin des Plantes (resembling Little Bob), Little Bob (maroon crimson), Illustration (pink), Scarlet Gem (scarlet), Gold Button (semi-double, white with yellow centre), and Mexico (white). Another of the pioneers in their culture was the Rev. F. Freeman, Vicar of Wickersley, Rotherham, and formerly of Middleton Vicarage, Leeds, who by his writings upon the subject in the paper named, caused much interest to be felt in them, and gave considerable impetus to their culture. I myself first became acquainted with summer flowering Chrysanthemums in 1881. I was then in charge of the Finsbury Park Nurseries, which comprised a small florist's nursery, with a considerable jobbing business attached, and made the acquaintance of George Martin of Stoke Newington, who had a similar nursery and business, and who made somewhat of a speciality of their culture, selling large numbers of them, dwarf sturdy plants in 48-size pots, flowering freely, in August and September. The sorts he then grew were Mammon (still one of the best early whites), Precocité, Jardin des Plantes, Illustration, Fred. Pélé, and Madame Piccol (Mr. W. Piercy is a red sport from the latter.)

In 1882 I returned to Sheffield to take charge of Oakbrook Gardens, and there found, in a neglected condition, stock plants of most of the varieties named above, which I at once set about cultivating in the best manner I could. In 1883 I received from my old friend, John Thorpe, formerly of Leicester, but then of Queens, New York, U.S.A., a large consignment of new American varieties, one portion of these being for Mr. Cannell, another portion for Mr. W. Bull, a third portion for Mr. W. Piercy, and the remainder for myself. The forwarding by me of Mr. Piercy's portion of the consignment led to a correspondence between us, which ended in his adding largely to the collection I then had. Amongst the varieties Mr. Piercy then sent to me were Salter's Early Blush, a very early and excellent dwarf free-flowering pink; Lyon, an excellent early dark Pompon; Fiberta, a charming yellow Pompon; St. Crouts and White St. Crouts, the latter a sport from the former. Mr. Piercy received the first-named in 1878 from a Mr. Kelman of Crouts, Guernsey, and hence it was named by him St. Crouts, but I believe it had previously been found by the Rev. F. Freeman in the gardens of Saddington Rectory, Leicestershire, and grown by him under the name of Saddington, so that it is now occasionally met with under each of these names. I also received Mrs. Cullingford, one of our most useful early whites; La Petite Marie, a very dwarf free-flowering white; Mdlle. Jolivart, an excellent white Pompon, imported from France in 1881; and Flora, which had only that season been sent out by Mr. Ware of Tottenham under the somewhat paradoxical name of "Early Late Flora."

Madame Desgranges I had obtained a year previously from Mr. Cannell. This immensely popular variety, which, more than any other, has caused early flowering varieties to become generally popular and everywhere cultivated, was discovered growing and flowering in a lady's garden in Wales in 1879 by Mr. Robert Parker, then of the Exotic Nursery, Tooting, Surrey, and was sent out by him in 1880. The following year a controversy arose as to whether Mr. Parker had been justified in terming it a new introduction, some stating that it was an old French variety, which had been catalogued by French nurserymen several years previous to his introduction of it, but these statements were, I think, never verified. As is, I suppose, tolerably well known, G. Wermig and Mrs. Burrell are both yellow sports from it, whilst Mrs. Hawkins is a sport from G. Wermig. This sport appeared in four places almost at the same time. More recent valuable introductions are Blushing Bride, imported from France in 1885; Alice Butcher, a very valuable sport from Lyon; and Miss Davis, a pleasing pink sport from Mrs. Cullingford. Mrs. J. R. Pitcher was raised by Mr. J. Thorpe, and

was included in the consignment I received from him in 1883, which I have previously mentioned. Mr. H. Jordan has in past seasons grown this fine variety more successfully than any other cultivator I am acquainted with. Grace Attick, a comparatively new variety, which I believe will yet become very popular, was also raised by Mr. Thorpe, and imported from America by Mr. Cannell in 1887, Mr. Laing receiving a certificate for it in 1889. It is perhaps the earliest of all to commence flowering; cuttings struck in March of this year commenced blooming in June, and will continue opening flowers until October. The flowers are large, pure white, and very graceful. They are most suitable for wreaths, bouquets, table decoration, or any other such purpose, and are produced so profusely as to thoroughly exhaust, and not infrequently kill, the plant. This variety grows freely in summer, but produces weakly cuttings in winter, which are found difficult to root when taken off. Golden Shah is an excellent early yellow Pompon, earlier and a much finer flower than Flora, but the plant is not such a good grower, nor so free in any way. It was raised, I believe, in 1889 at Mr. Ware's Tottenham Nursery from seed saved in England by Mr. Piercy.

During the past two seasons a very large number of early flowering varieties have been raised in France and exported to this country, most of them, however, being what we term October flowering, and therefore scarcely ranking with those I have been commenting upon. Those amongst them which gave me most satisfaction last season were P. Radalli, a white Japanese, very similar to our old friend Madame Desgranges, but purer in colour; Arthur Crepey, pale primrose, otherwise similar to the last; and Madame Foucher de Cariel, a really good and useful decorative variety. The plant is a good and vigorous grower, but very dwarf and bushy; it flowers very freely, and the blooms are of a pleasing and popular shade of colour—orange amber, or, as the ladies term it, terra cotta.

(To be continued.)

GROWING GRAPES FOR PROFIT.

SINCE the publication of Mr. A. F. Barron's book on Vines* in 1883 it has been recognised as the standard work on Grape growing. Its practical and comprehensive character was quickly recognised, and its usefulness to all classes of cultivators was proved by the demand for copies, which subsequently led to the necessity for a second edition. This being exhausted in its turn, a third has had to be prepared, and has recently been issued. In the time that has elapsed since the book first saw the light great changes have taken place. Horticulture in general, and fruit growing in particular, have shared in a marked degree in the general progress of the world. Since 1883 there has been an enormous development in the culture of both indoor and outdoor fruit, and considering that Grape growing is to a very large extent restricted to glass structures of considerable dimensions, necessitating some amount of capital to erect and furnish, its increase is almost phenomenal. Mr. Barron's splendid work has many admirable features, and abounds in practical information on Vines and their management, but there is no chapter in it so full of interest and significance as that in the new edition which deals with the commercial aspect of Grape-growing. It indicates a scale of operations of which the magnitude can hardly be grasped from the statistics supplied, striking though the latter are. To those who have never entered a market establishment it requires a considerable effort of imagination to conjure up the picture of an acre of Grapes, and this represents but a small portion of some of the great establishments to which reference is made. We make a few extracts from the book on this subject as showing the marvellous growth of Grape culture as a business industry, leaving the salient features of this and other branches of culture to be gleaned from a perusal of the book.

GRAPES AND TOMATOES.

The question as to what has led to the rapid growth of Vine culture for profit is one of much interest. Mr. Barron suggests a cause that would not have occurred to many, and supports his view with much force and cogency. "It is important," he says, "to note the causes which have led to this result. Partly, no doubt, it is owing to the introduction into cultivation of good late-keeping varieties of Grapes. Chiefly, however, it is due to the Tomato. Extraordinary as it may at first appear, it is the great popularity and demand for Tomatoes which has rendered the cultivation and the present enormous supply of Grapes possible. Both crops requiring much the same treatment, houses erected for Grapes are at first cropped with Tomatoes, which, producing an immediate return, help the growers to tide over the first two or three years whilst the Vines are getting established; in this way we are provided with a bountiful supply of the most luscious and enjoyable fruit this earth produces."

HOW THE TRADE HAS GROWN.

"The magnitude of the trade in Grapes that has thus arisen is of the utmost importance, and can scarcely be over-estimated. An enormous amount of capital has been called into requisition, and is engaged in the furtherance of this trade. Directly and indirectly many thousands find employment, and are thus benefited by Grape-growing. We do not ourselves know of any industry that can compare, or which has

* *Vines and Vine Culture*. By ARCHIBALD F. BARRON. London: *Journal of Horticulture* office, 171, Fleet Street, E.C.

done so much in so short a time for the welfare of the people. The approximate supply in 1886 of what are termed English-grown Grapes amounted to about 400 tons, one commission agent in Covent Garden (Mr. Monro) disposing of 40,000 baskets, or an equivalent of about 250 tons. During the past year (1891) this quantity has been greatly exceeded. The greatest quantity ever sold in one day was in October, 1891, and amounted to 4 tons = 750 baskets."

WHERE THE GRAPES ARE PRODUCED.

"The chief producing establishments are to be found within a comparatively easy distance of London, so that the fruit may be delivered by van without the intervention of the railway; the Grapes are thus obtained without a blemish in the best possible condition. Several of the vineyards or Grape-growing establishments are of a leviathan character, whole fields being covered with glass, presenting in some parts of the country quite a novel feature in the landscape. Every year these are more and more extended. At the present time the largest growers are probably the Messrs. Rochford, who in their several establishments in the neighbourhood of Cheshunt, Broxbourne, &c., have over 50 acres covered with glass, about one-half of which is planted with Grapes, from which they calculate to produce about 300 tons a year, when the Vines come into full bearing—an acre of ground covered with glass being estimated to produce 15 tons of Grapes annually. Reckoning the value of the crop at 2s. per pound, the gross return per acre thus amounts to £3360. Of other large growers in the London district may be named Mr. Peter Kay, of Finchley; Mr. Ladds, of Bexley and Swanley; Mr. Sweet, of Whetstone; and many others.

"Another great centre for Grape-growing has arisen at Worthing, in Sussex, from whence some 300 tons are sent to Covent Garden every year, and is still extending; the principal growers are Mr. N. Piper, Mr. Bushby, Mr. G. Russell, Mr. Sams, and Mr. Beer. In Scotland also Grapes are largely grown for London markets by Messrs. Thomson and Sons, at Clovenfords, Galashiels; and Mr. D. Beatson, of Kirkcaldy. Of Grapes grown in the Channel Islands, especially Guernsey, the quantity is simply enormous. According to official returns in 1876 the shipments, *via* Southampton, amounted to 50 tons, whilst in 1886, ten years later, the total was over 500 tons, of which one salesman in Covent Garden (Mr. G. Monro) sold on commission over 300 tons, and in 1890-91 about 350 tons. Although the production has very greatly increased, the quantity sent to Covent Garden does not appear so great, increased facilities for transmission having spread the trade in these low-priced Grapes to the provincial towns, Mr. Monro, for example, selling in Manchester, on commission last year, over 80 tons of fruit."

THE MOST PROFITABLE VARIETIES.

In Grape-growing, as in many other branches of commercial horticulture, it is found that success is not to be gained by a multitude of varieties. It is far more profitable to restrict operations to one or two sorts for which a steady demand and fair prices exist. Although the general principles of culture are the same with all, there are certain modifications in treatment which it is only possible to provide in an economical manner by selecting one or two leading varieties and keeping each to itself, then growing it so well and extensively that a small profit per pound on a large bulk of fruit may give a satisfactory aggregate return for the capital and labour invested. "Of varieties grown for market," Mr. Barron says, "the chief for early and summer use, up to the month of December, is the Black Hamburgh; succeeding this, for late use, is the Gros Colman. No other Grapes command the market to any extent. Lady Downe's Seedling, a few years ago, was the favourite late Grape; now it is of comparatively little value. Black Alicante commands a fair price up to a certain period, and Madresfield Court is approved as an early sort. Amongst white Grapes the Muscat of Alexandria is the first favourite, and Buckland Sweetwater second." Probably Gros Colman well grown brings the best prices. When well cultivated this Grape has that rare combination—magnificent appearance and good quality. Medium-sized bunches, with large and perfectly coloured berries, are what dealers require, and market growers turn them out as though from a mould—living pictures of beauty and quality, that invariably command purchasers. The name of Mr. Witherspoon, of Chester-le-Street, is worth adding to those who are named in Mr. Barron's work as having had a large share in the development of commercial Grape-growing. His culture of Gros Colman and Alicante is certainly remarkable.

WILL THE PRICES KEEP UP?

Passing over the information that is supplied on the methods of culture pursued in the great Grape establishments, also on that respecting the important question of keeping fruit, but which must be carefully studied by intending growers, we come to the subject of prices. May they be expected to keep up? will be the question suggesting itself. Mr. Barron gives a negative reply. In the 1887 edition of his work he gave a list of prices for fruit supplied by the well-known Covent Garden agents, Messrs. Webber & Co., which were from 25 to 50 per cent. lower than those in 1876, and predicted that there would be a further decline. The prediction has been fulfilled, "the prices from Messrs. Webber's books of last year (1891) being 25 per cent. lower in every month (excepting October) than in 1886, and the tendency is still downward, although the prices at the present time seem to be as low as it would appear possible for them to pay, even with skill and capital combined.

The chief growers do not, however, trouble themselves much after sensation prices. They base their calculations on the actual costs and gross returns; and argue thus—that to sell a ton of Grapes at 2s. or 3s. per pound is better than, as formerly, to sell a few hundred pounds at 10s. or 20s. per pound—prices which were practically beyond the reach of the consumers. Cheap prices now enable retail fruiterers to maintain a supply on sale at all times, thus increasing the consumption. This fall in prices has a tendency to induce growers to crop too heavily, and in this way the general quality of the Grapes is not maintained."

ENGLISH GRAPES FOR AMERICA.

It would be easy to quote further from this deeply interesting chapter, particularly from what is said on packing Grapes for market, and on the structures in which the great bulk of the fruit now sent to market is grown, but a perusal of the work will afford information on these and other points in procedure that are of prominent importance. We conclude with a gratifying testimony to the quality of British Grapes in the information that an export trade in them to America is growing up. "A great trade in English winter Grapes seems likely to become established with America. During the past two seasons regular consignments of English Grapes have been sent from this country. They have been found to travel well and to arrive in good condition, and prove of superior quality to American produce during the winter season. They are sent by the Cunard steamers, reaching New York about ten days after being cut; some are sold on arrival at New York, whilst others are sent on to Philadelphia, Boston, Pittsburg, Chicago, &c."

It is a little consolation that if home growers of Apples cannot beat the American cultivators, we are able to produce Grapes of the highest quality, and find a market for them in the States.

HARDY FLOWER NOTES.

TANTALISING to the flower grower is the weather of the season. Days of constant rain follow in close succession. Sometimes, fortunately, we have had brighter days, when, as Longfellow says in "Evangeline"—

"Bright rose the sun next day; and all the flowers of the garden
Bathed his shining feet with their tears, and anointed his tresses
With the delicious balm that they bore in their vases of crystal."

All too seldom have these days come. How welcome are they when they appear, both to us and to the flowers, to which they seem to bring fresh beauty! Nothing can quench that beauty, and now it seems enhanced by the past disappointments and by the thought of the coming gloomy winter. There is much to view and to praise.

COLCHICUMS AND SNOWFLAKES.

The Colchicums, or Meadow Saffrons, have begun to open, and in some gardens further inland *Crocus speciosus*, the blue autumn Crocus, has opened its brilliant cups, although with me, where everything is late this autumn, none of the Crocuses are yet above the surface of the soil. The delightful little autumn flowering *Leucoion* or *Leucojum*, *L. autumnale*, is, however, in full flower, and excites much admiration, so delicately beautiful are its tiny pendent Snowdrop-like flowers with their tinge of pink at the base. This is now thoroughly established, and is well worthy of being planted in quantity in mild and favoured localities. A word of warning may not be out of place to those growing this tiny autumn Snowflake for the first time, and that is to take care not to destroy the grass-like foliage when it appears in spring. It is readily mistaken for grass by the careless or hurried weeder. For this chaste little flower a sunny, sheltered position in light soil will be found the most suitable. Mr. Baker, in his "Handbook of the Amaryllideæ," gives its native habitats as "Portugal and Morocco to the Ionian Islands." *L. autumnale* of Linnæus is the *Acis autumnalis* of Salisbury.

LILIUMS.

Several Lilies are now well in bloom, and among the most reliable and satisfactory for the hardy flower garden are still the varieties of *L. tigrinum*, the well known Tiger Lily. The variety *Fortunei* or *splendens* is in many respects superior to the typical form, being taller in stature and having larger flowers. The double Tiger Lily (*L. tigrinum* fl.-pl.) is apparently becoming a greater favourite, and is met with in gardens much more frequently than formerly. It seems of comparatively recent introduction, having been only introduced about the year 1869 from Japan. It appears to me to be the double form of *L. t. Fortunei*, and is later in flowering than the typical *tigrinum*. Its very double blooms are curious and fine, and the ease with which the varieties of the Tiger Lilies may be increased by planting the bulblets which are so freely produced on the flower stems, should enable admirers of the double form to add rapidly to their stock. The price is, however, so low that it seems hardly worth while to wait for these bulblets attaining a flowering size. In some of our works of reference various double Lilies are mentioned, but few of these are seen in general cultivation. I have not as yet met with any of the double forms of the Martagon Lily (*L. Martagon*), or with *L. pomponium* fl.-pl. Several variegated leaved Lilies seem also to be in existence, but these are apparently rare, although the variegated form of *L. candidum* is comparatively cheap.

THE COMPASS PLANT.

Although we seem almost to have a surfeit of yellow flowering composites at this season, one of the most striking for a large garden or the shrubbery is one of the Silphiums or Compass Plants. Longfellow in "Evangeline" speaks of it thus:—

"Look at this delicate plant that lifts its head from the meadow,
See how its leaves all point to the north, as true as the magnet;
It is the Compass Flower, that the finger of God has suspended
Here on its fragile stalk, to direct the traveller's journey
Over the sea-like, pathless, limitless waste of the desert."

It seems strange to think of the poet thus describing any of the Silphiums as a "delicate plant," and speaking of its "fragile stalk." We can only suppose that he had never seen the flower, or that he had another plant in his mind when he wrote. At all events the Silphiums are plants of grand effect in suitable positions. One of these, *S. perfoliatum*, was very fine a few days ago in the garden of Mr. James Davidson of Summerville, Dumfries. It was 7 or 8 feet high, and bore a profusion of flowers. It is, perhaps, a little coarse in habit, but is very suitable for large gardens.

PLATYCODONS.

Very attractive in the same garden was a well-grown plant of *Platycodon Mariesi*, one of the finest, if not the finest, of our autumn-flowering Bellworts. It is rather aptly called the Balloon Flower from the resemblance of the flowers to a balloon, and the fine blue colour, combined with the form of the blooms, will make it an always popular plant. *P. Mariesi* was growing about 1 foot in height. The Platycodons are but seldom met with, even in good gardens, and it is desirable that they should be brought more prominently before the hardy plant grower. The generic name is derived from *platys* (broad), and *kodon* (a bell). There are several species or varieties in cultivation, and two double or semi-double forms of *P. grandiflorum* are still rare, and comparatively expensive. Propagation may be effected by means of seeds or division in spring, and by cuttings of young shoots placed under a handlight in summer. A sandy loam is the most suitable soil.

RANUNCULUSES.

Among the many species of Ranunculuses in cultivation we find a large number of very beautiful plants, and I was much pleased with a beautiful little member of the genus which I saw recently for the first time in the well-tended and interesting garden of Mr. John Burns of Woodside, Giffnock, Renfrewshire. *R. Bertoloni*, as the plant was named, is a very dwarf species, with a beautiful white flower only a few inches above the soil, and it appears to be one of the most desirable alpine species. I have been unable to obtain any particulars regarding *R. Bertoloni*, but I believe it will be found to be of Italian origin. It is perfectly hardy, and was growing well in a good loamy soil. It does not seem to be known to the nursery trade generally, and, so far as I am aware, the stock is in the hands of one or two firms only in this country. In the same garden the tiny little *Arenaria balearica* was grown in a manner I have never seen surpassed, rambling over and covering stones in the most delightful way.

STOKESIA CYANEA.

I spent a few days in the vicinity of Glasgow, and had the pleasure of seeing a considerable number of gardens containing good collections of hardy flowers. In a small greenhouse in the garden of Mr. Watson of Alexandria, N.B., I saw a good plant of *Stokesia cyanea*. It was quite a pleasure to see this pretty flower in bloom again. In Scotland, at least, it cannot be relied upon to flower outside without protection unless pushed on under glass in spring, and then planted out. It is a loss to our gardens that we cannot bloom this *Stokesia* in a natural way; it is so beautiful with its deep coloured Cornflower-like blossoms. *S. cyanea* was introduced from Carolina in 1766, and was named by L'Heritier in honour of Dr. Jonathan Stokes, the coadjutor of Withering in his "Arrangement of British Plants." Doubtless its late blooming habit is the cause of its rarity in gardens.

ROCKETS.

Few things gave me more pleasure than to see the careful way in which the real double white Scotch Rocket is preserved by many of the amateurs around Glasgow. We often have inquiries as to where this is to be obtained, and frequently what is known as the French double white is substituted for the true plant. The Scotch variety is much dwarfer in habit and purer in colour than the other. I had also the pleasure of seeing a still rarer plant, the true double crimson Rocket, a most exquisite flower indeed, but very scarce, and hardly to be obtained anywhere. I need hardly say it is dearly prized by the few who have the happiness to possess it.

But time is flying, and flowers many still brave the breezes. Asters of various shades are now in full display. The bright *Lilium flavum* bedecks the rockery and borders with its brilliant yellow flowers. A number of *Heaths* are very pleasing with their sober beauty. *Gladioli*, slowly opening, stand like gaily uniformed sentinels. The silky leaved *Androsace lanuginosa* still shows its pretty and delicate blossoms on the rockwork. *Campanulas* in variety are still attractive. Showy *Montbretias* and stately *Kniphofias* add their welcome colour to the scene, and many other flowers come to welcome the cool breezes of September, and to close brightly the season of flowers.—S. ARNOTT.

HELENIUM AUTUMNALE STRIATUM.

THE number of yellow Composites flowering in late summer and autumn is so great that there is danger of some gardens being overdone with them. Yellow is a colour that requires to be used with much greater care and judgment than are generally exercised if garishness and vulgarity are to be avoided. If only for this reason a hearty welcome would be extended to the beautiful *Helenium* exhibited by Mr. T. S. Ware at the Chiswick Conference on Begonias. It imparts a very desirable break in colour while retaining the hardiness and floriferous character of its relatives. The flowers are about 2 inches in diameter. The disc is maroon and gold, the florets rich red striped with yellow.

FIG. 37.—HELENIUM AUTUMNALE STRIATUM.

Its distinctness was readily recognised, and a first-class certificate—an honour rarely won by a variety of a hardy plant—was accorded. Fig. 37 represents *Helenium autumnale striatum*, which from its rich and distinct colour will be a desirable acquisition for any flower garden.

THE COMMERCIAL VALUE OF ANIMAL MANURES AS NITROGENOUS DRESSINGS.

AN important investigation was undertaken a short time ago by two well-known French authorities, MM. Müntz and Girard, which had for its object a comparison of the value possessed by different manures composed of animal matters in their relation to nitrogenous dressings. This investigation yielded results which may well be carefully noted by practical men; too often scientific investigations result in much literature, but are barren of anything which the practical agriculturist can make use of.

We have known for some time that these nitrogenous materials

cannot be of any service until the nitrogen which they contain is transformed into that state of chemical combination known as the nitrate. Hence the aptitude of organic manures to undergo the process of nitrification by means of the nitrifying organisms which are present in the soil may be taken as a measure of their activity as manurial dressings.

A great many kinds of animal matter were examined by MM. Müntz and Girard, and their relative value as nitrogenous dressings compared, with the result that all commercial manures are divided by them into three classes—viz.,

- A. Dried blood, dried flesh, bone refuse, and guano.
- B. Burnt leather, woollen waste, dried night soil.
- C. Unburnt leather waste.

These different substances were examined by ascertaining the proportion of nitrate formed during a given time by the method of mixing quantities of each substance under similarly comparable conditions, and containing each an equivalent quantity of nitrogen with soil containing nitrifying organisms.

With regard to the members of Class A, MM. Müntz and Girard find that they all undergo the process of nitrification rapidly. Dried blood, dried flesh, bone refuse, and guano are nearly as active as the manures of mineral origin, and they have almost the same effect on the crops that are treated with them as the mineral manures.

The manures which appear in Class B do not undergo the process of nitrification so rapidly as those in Class A, and the result is that their action is usually extended during more than one season, thus nourishing the crop of the next year, though not to such an extent as in the first year.

The third class, which is occupied by unburnt leather waste, only sustains the nitrification so slowly that during the first year there is no appreciable effect upon the crop that is dressed with it. It is evident that unburnt leather should only be used in compost heaps, for the conversion of its nitrogen into nitrate by the nitrifying organism proceeds far too slowly for it to be directly available in nourishing the crop.

Experiments made upon a practical scale (not in pots—a method which agriculturists often view with suspicion) have yielded the following numerical results for the various manures:—

Amount of nitrogen utilised in two years.	Class A	60 per cent.
	" B	40 "
	" C	20 "

MM. Müntz and Girard conclude that the unit weight of nitrogen often costs more when purchased in the form of organic manure than when purchased as saline manures; and they are of opinion that it would be much more reasonable to pay the higher price at which saline manures are placed upon the market, because in this case the nitrogen they contain can be immediately made use of, and—which is by no means the least important consideration—the quantity of manure applied can be fairly accurately arranged according to the particular requirements of the crops which are to be dressed with it.

A rather humiliating confession is made by these investigators when they say that the ordinary chemical methods used in the laboratory cannot be relied upon to give any useful information respecting the relative value of animal manures; in fact, they say that no practical value can be attached to them.—N. T. J. (in *The Agricultural Economist*).

ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 20TH.

THE meeting at the Drill Hall on Tuesday was one of the best of the ordinary gatherings of the season. Orchids were not, it is true, very largely represented, but there were a few of exceptional beauty, while the general display of plants and flowers was quite above the average. Fruit, too, was splendidly shown, the collections from the Royal Gardens at Windsor and from Sawbridgeworth being very fine. Potatoes from Chiswick were of considerable interest.

FRUIT COMMITTEE.—Present: Philip Crowley, Esq. (in the chair), Messrs. T. Francis Rivers, R. D. Blackmore, W. Wilks, George Taber, T. J. Saltmarsh, A. Dean, J. A. Laing, G. Cliffe, W. Bates, G. Wythes, James Hudson, H. Balderson, G. Norman, W. H. Divers, J. Willard, A. Moss, G. W. Cummins, and Dr. Hogg.

A magnificent contribution came from Mr. Owen Thomas, Royal Gardens, Windsor. It comprised about forty dishes of Peaches and Nectarines, splendid examples gathered out of doors. Barrington, Sea Eagle, Walburton, Princess of Wales, and Prince of Wales Nectarine were particularly fine. There were also excellent dishes of Stone's, Brown's Codlin, Lord Grosvenor, and Frogmore Prolific Apples; Doyenné Boussoch, Autumn Josephine de Malines, and Beurré d'Amanlis Pears; two baskets of *Morus nigra*, a large conical Mulberry; a dish of Quinces, and Nottingham Medlars, twenty dishes of Plums, including one of the Frogmore Damson, a large oval-shaped fruit; fourteen Melons, a dozen grand Smooth Cayenne Pines, fine clusters of Alicante and Raisin de Calabre Grapes, also a basket of Black Hamburgs cut from the Cumberland Lodge Vine, another from the Hampton Court Vine, and a third of the Strawberry Grape, a diminutive fruit. A silver-gilt medal was recommended. Messrs. T. Rivers & Son, Sawbridgeworth, had a very fine contribution, comprising splendid fruit of Sea Eagle, Albatross, Princess of Wales, Nectarine and Gladstone Peaches, also two fine

seedlings, both large and very handsome fruits; Pond's Seedling, Late Transparent, Monarch, and a seedling Plum, Ribston Pippin Apple and a seedling Pear. A silver Banksian medal was recommended for this fine display. Mr. Willard, Holly Lodge, Highgate, was accorded a vote of thanks for a splendid dish of Barrington Peaches grown out of doors; and Mr. Mortimer, Farnham, received a similar recognition for a dish of fruit of *Ribes sanguineum*. The Rt. Hon. Lady Theodore Guest, Inwood House, Henstridge (gardener, Mr. Wilkins), exhibited a dish of Mangoes (*Mangifera indica*), and was awarded a cultural commendation. Mr. Molyneux, Swanmore Park Gardens, Bishop's Waltham, was accorded a vote of thanks for Worcester Pearmain Apples, large and very full of colour. Mr. J. Tegg, Beardwood Gardens, Wokingham, exhibited a good seedling Melon, a round pale yellow evenly netted fruit, orange fleshed, and of excellent flavour (award of merit).

Messrs. Sutton and Sons received a first class certificate for their Prizewinner Runner Bean (see below). Mr. G. T. Bodley, 99, Loughborough Park, London, S.W., sent a collection of Apples grown in a London back yard, some being excellent examples, and a cultural commendation was awarded. Messrs. G. Bunyard & Co. received a first class certificate for Runner Bean, Hill's Prize (see below). Forty varieties of Potatoes came from the Royal Horticultural Society's garden, and four received first class certificates (see below). Awards of merit were made to Crawley Prizetaker (Cheal), a large handsome kidney likely to be good for general use and show; King of the Earlies, a medium sized kidney; Paul's White Round, an excellent round of good size, even and an excellent cropper; and Harris's White Russett. Messrs. Carter and Co. sent growths of the fine Tomato Blenheim Orange, well clothed with fruit (award of merit).

FLORAL COMMITTEE.—Present: J. Fraser, Esq. (in the chair), Messrs. O. Thomas, B. Wynne, R. Dean, R. Owen, G. Phippen, H. B. May, Chas. T. Druery, F. Ross, W. C. Leach, C. F. Bause, J. Walker, W. Bain, C. Jefferies, N. Davis, E. Mawley, T. Baines, C. Noble, H. Turner, G. Paul, W. Watson, H. H. D'Ombain, and T. W. Girdlestone.

Some excellent exhibits were placed before this Committee. Messrs. Dobbie & Co., Rothesay, N., sent a splendid collection of Fancy, Show, Cactus, and Pompon Dahlias, also a number of Fuchsias, Violas, French and African Marigolds, and Antirrhinums (silver-gilt Flora medal). The Dahlias were exceedingly good, and among them were some fine varieties. Two Show sorts, Canary Bird and Conquest, sent out this year by Messrs. Dobbie & Co., were specially good; the first-named is a rich yellow, and the latter a light magenta. An award of merit was adjudged for the strain of French Marigolds shown by Messrs. Dobbie & Co., who also exhibited blooms of a "new" type of single Dahlias, which were passed. Messrs. G. Paul & Son, Cheshunt, had a collection of hardy flowers bright and fresh in appearance (bronze Banksian medal). An effective group of Crotons was staged by Messrs. B. S. Williams & Son (silver Banksian medal). The plants were richly coloured, and made a pleasing contrast to the hardy and other flowers shown. Messrs. J. Laing & Son, Forest Hill, had a group of miscellaneous plants tastefully arranged (silver Banksian medal). They also exhibited blooms of a neat double Begonia named Wm. Allen Richardson made up in sprays. In colour the flowers somewhat resemble the Rose of that name, and are most effective arranged with *Asparagus plumosus* and Fern fronds. Some fine blooms of other double Begonias were likewise shown.

Messrs. F. Ross & Co., Merstham Nurseries, Surrey, staged a plant of *Aristolochia gigas* var. *Sturtevantii*, for which a first-class certificate was awarded. This is referred to elsewhere. Mr. Quarterman, gardener to C. E. Smith, Esq., Silvermere, Cobham, sent a collection of Pine cones, for which a vote of thanks was accorded. Mr. R. Owen, Maidenhead, showed a white Chrysanthemum named Princess May, a seedling from Madame C. Desgranges, and an English seedling designated Harvest Home. Messrs. Perkins & Sons, Coventry, staged several Dahlias, one of which named Matchless was adjudged an award of merit. This is described below. A small group of Ferns came from Mr. H. B. May, Dyson's Lane, Edmonton, and amongst them some choice varieties were noticeable. One named *Pteris nivalis* was awarded a first-class certificate, and is referred to elsewhere. A silver variegated Elder (a sport), shown by Miss Alice de Rothschild, Eythorpe, Bucks (gardener, Mr. Gibbs), was adjudged an award of merit, the foliage being exceedingly pretty. A vote of thanks was accorded to Messrs. Veitch & Sons, Royal Exotic Nursery, Chelsea, for a box of their hybrid *Streptocarpus*.

Dahlias were well represented. Mr. T. S. Ware, Tottenham, staged a few bunches of single varieties. W. Keith, Esq., Cornwalls, Brentwood (gardener, Mr. J. T. West), had a splendid collection of Show, Fancy, Cactus, and Pompon types. Among the latter, two, named Arthur West and Tommy Keith, were adjudged awards of merit. These are described below. Mr. C. Turner, Slough, had a stand of Show Dahlias, and another of Pompons, of sterling merit. One of the Show varieties, named Kathleen, was adjudged an award of merit, and is referred to elsewhere. Mr. A. Rawlings, Romford, staged a fine collection of Show and Fancy varieties, for which a silver Banksian medal was recommended. The flowers were bright in colour, R. T. Rawlings, Queen of the Belgians, George Rawlings, Mrs. Vagg, and Arthur Rawlings being specially good. Mr. S. Mortimer, Swiss Nursery, Rowledge, Farnham, also had a collection of Dahlias, and a bronze medal was recommended. The best of these were Majestic, Maud Fellowes, Lord Salisbury, and John Walker.

Messrs. Reid & Bornemann, Sydenham, showed a white hairy-petalled Chrysanthemum named George Jones, which was apparently passed,

however, by the Committee. Mr. C. Holden, Harwich Road, Ealing, sent a collection of miscellaneous plants, for which a bronze Banksian medal was recommended. A vote of thanks was accorded to Messrs. R. B. Laird & Sons, Edinburgh, for a box of their Keir Prince Carnation, a dark variety. Mr. R. Dean, Ealing, sent a few blooms of *Crocus speciosus*, and Messrs. Pitcher & Manda, Hextable, two plants of *Pteris Wallichiana*.

ORCHID COMMITTEE.—Present: Dr. Masters (in the chair), Messrs. J. O'Brien, S. Courtauld, W. H. White, H. Williams, E. Hill, C. Pilcher, T. W. Bond, F. Sander, J. Douglas, T. B. Haywood, and J. Jaques.

The duties of this Committee were light, not many Orchids being shown. W. Walker, Esq., Brettargh Holt, Kendal, sent two splendid baskets of *Saccolabium Blumei*, each having eight racemes of bloom. A vote of thanks was accorded. Messrs. Hugh Low & Co. sent a collection comprising *Cattleya bicolor* Wrigleyana, *Vanda Kimballiana*, *V. K. delicata*, *Saccolabium Blumei majus*, *Vanda cærulea*, *Cypripedium radiosum superbum*, *C. Parishii*, and *Dendrobium formosum giganteum*. A vote of thanks was given. Messrs. B. S. Williams & Son exhibited *Oncidium incurvum album*, a white variety of *incurvum*. Messrs. Sander & Co. sent the beautiful *Cattleya aurea*, a plant being shown carrying two fine flowers. The creamy yellow sepals and petals and the large broad crimson lip with the deep golden veins are gloriously beautiful. Sterling plants such as this are always a pleasure to see, whether new or old. Messrs. Sander & Co. also contributed a collection of *Cypripediums*, which included *C. picturatum*, *C. hybridum* Maynardi, *C. h. Eyermannianum*, *C. Chamberlainianum*, *C. radiosum*, and *C. Macfarlanei*; also *Odontoglossum aspersum*, *O. Harryanum*, *Masdevallia Measuresiana*, *Angræcum bilobum* Sander's variety, *Dendrobium Phalænopsis Schröderiana*, and others. C. L. N. Ingram, Esq., Elstead House, Godalming (gardener, Mr. Bond), sent *Cypripedium Wendlandianum*. T. Statter, Esq., Stand Hall, Manchester (gardener, Mr. Johnson), sent *Cattleya Statteriana* (first-class certificate, see below); and *C. aurea* Statteriana. The latter was one of the features of the meeting. It was certificated in 1890, but probably many had not seen it, and were very glad of the opportunity to do so. The sepals and petals are of a uniform pale yellow, the side lobes of the lip are of the richest nankeen yellow, the centre of the apical portion is brownish crimson, and lines of crimson radiate into the throat. It is a noble flower. J. Foster Alcock, Esq., North Church, Berkhamstead, sent *Catasetum Bungerothi* with seven flowers (vote of thanks). Messrs. J. Veitch & Sons sent *Cattleya* × *Minucia* (award of merit, see below); and from L'Horticulture Internationale came *Cyrtopodium Alicæ*, *C. macranthum*, and *Odontoglossum præstans*.

CERTIFICATES AND AWARDS.

Potato, Reading Giant (Fidler).—A very large rough kidney, a very heavy cropper, and a pronounced disease resister. It is a promising market variety (first-class certificate). This and the others to be named have given the greatest satisfaction at Chiswick.

Potato, Mary Anderson (Fletcher).—A long, pointed kidney, medium size, smooth and pale; a fine cropper (first-class certificate).

Potato, Quantity and Quality (Johnston).—A round, rough tuber, somewhat resembling Schoolmaster, very even in size, there being few small ones. It is a very heavy cropper, a good disease resister, and cooks well (first-class certificate).

Potato, The Canon (Dean).—A large flattened kidney, somewhat rough skin, an excellent cropper, and likely to prove valuable either for show or general purposes (first-class certificate).

Runner Bean, Hill's Prize (Messrs. Bunyard & Co.).—A very fine Bean with long even pods. It is a good cropper and received three marks at Chiswick (first-class certificate).

Runner Bean, Prizewinner (Messrs. Sutton & Sons).—An excellent Bean of the Ne Plus Ultra type, having large handsome pods and a heavy cropper. It has received three marks at Chiswick (first-class certificate).

Aristolochia gigas var. *Sturtevantii* (Messrs. F. Ross & Co.).—This is a fine variety. The plant shown was in an 8-inch pot and had one bloom about 15 inches in length and a foot or so in diameter, with a tail some 3 feet long. The outside is a creamy white, a portion of the centre being rich velvety maroon (first-class certificate).

Dahlia Matchless (Perkins & Sons).—A Cactus variety, medium in size, and of a rich maroon colour, the centre petals being very dark (award of merit).

Silver Elder (Mr. Gibbs).—A pretty decorative Elder with white and green foliage, the young leaves being particularly effective (award of merit).

Pteris nivalis (H. B. May).—An elegant Fern, resembling in growth *P. Regina*, which was figured in these pages a short time ago, but whiter in appearance (first-class certificate).

Dahlia Tommy Keith (W. Keith, Esq.).—A Pompon variety with neat white and dark crimson flowers (award of merit).

Dahlia Arthur West (W. Keith, Esq.).—A Pompon variety with small dark crimson flowers of perfect symmetry (award of merit).

Dahlia Kathleen (Mr. C. Turner).—A Show variety of perfect symmetry, colour soft lilac, creamy centre (award of merit).

Cattleya Statteriana (T. Statter, Esq.).—This is a magnificent plant, and the wonderful size and exquisite colouring of the lip aroused the greatest admiration. It is an imported plant, and probably the only one in the country. Nothing definite is known about its parentage, but it is, no doubt, a natural hybrid, and many of its characters point to a *C. aurea* and *C. gigas* union. The petals are broad and of a dull ivory white, though we are informed that five or six days ago they were much purer

than they are now, having faded somewhat. They are very broad, but recurve so much that the breadth is lost, and are elegantly crimped or fimbriated. The sepals have a faint yellow tinge. The lip is, however, the most striking feature of the flower. It is very long and broad, rounded near the throat, but curving down towards the apex, which is elevated and fimbriated. The apical area is rich velvety crimson, purplish flakes radiating into the throat. The side lobes have the rich nankeen yellow of *C. aurea*. The outer surface of the tube is deeply suffused with carmine, and the charm of the flower is completed by a beautiful rosy carmine feathering round the edge, almost like a heavy-edged Picotee (first-class certificate).

Cattleya × *Minucia* (Messrs. Veitch & Sons).—This is a garden hybrid between *C. Loddigesi* and *C. labiata* var. It is a delightfully tinted flower, the sepals and petals being a glowing rosy lilac, inclining to mauve. The lip is fimbriated and somewhat narrow, the side lobes each having a conspicuous carmine patch. The entrance to the throat is suffused with pale yellow (award of merit).

THE REV. C. WOLLEY DOD ON THE VARIATION OF HARDY PLANTS.

A paper on the "Variation of Hardy Plants under Cultivation," by the Rev. C. Wolley Dod, was read at the afternoon meeting of the Royal Horticultural Society on the above-mentioned date. There was but a small attendance of Fellows, and in the unavoidable absence of the essayist the paper was read by the Rev. W. Wilks. Mr. G. Paul presided.

In opening his subject Mr. Wolley Dod observed that the chances of variation in plants were multiplied when the latter were under cultivation. In a natural state the plants ripened comparatively few seeds, whereas when cultivated the reverse was generally the case. Common sources of error regarding the variation of plants, he said, occur when observations are made carelessly. After many years' experience he was convinced that the common single Daffodil did not develop into a double bloom; neither did the single Primrose change colour through any system of cultivation. Then as to the stature of plants, he had noticed that many seedlings from wild plants showed an increase in height when cultivated in gardens, as, for instance, *Campanula glomerata*; whilst some, on the other hand, degenerate. As to variation of colour, he had seen no real change unless attributable to some other plant; but many of the flowers in the damp soil in his garden varied much. What was a pale blue Primrose in the garden of a friend became a dull red in his soil in Cheshire. The first change of colour was as likely to take place in a wild plant as in a cultivated one, but it would be less noticeable. In the lanes in Cheshire he had seen *Campanula rotundifolia* vary much, also *Veronica spicata* in other places. Regarding the variation of seedlings, the essayist remarked that the white Foxglove rarely gave him a white flower from home-saved seed, neither did the white Harebell. Twenty years ago he planted a white Musk Mallow in his garden, and for ten years the plant produced white flowers; then he introduced a pink-flowered sort, and ever since had been obliged to weed the latter out.

Concerning the fertility of garden hybrids no rule, he said, could be laid down. Some were barren, others fertile. Among the Columbines it was never known what home-saved seed would produce, according to his experience, and the Dianthus were also very variable. Narcissi seemed to hybridise in almost every way, but he had never seen a hybrid *Crocus*. As to the cause of some plants producing double flowers, he thought that hybridisation had more to do with this than luxuriant growth. Seedlings of Michaelmas Daisies show a tendency to produce double flowers, and *Aquilegias* would also persist in yielding double blooms.

Professor the Rev. G. Henslow, in the brief discussion which followed, said he had long been anxious to find out the real cause of the dwarfing of plants, particularly the product of florists. If gardeners and florists would endeavour to find out the cause it would be most useful. Then, again, no one as yet had settled the actual cause of the production of double flowers. It was, so to say, a form of disease, a destruction of stamens and pistils, but no special reason for this special disease could be assigned. According to his experience rather a dry position tends to produce it. Daffodils and Bluebells introduced from a wild state into his garden degenerated, the latter in many instances producing pink short flowers instead of elongated blue ones as when growing wild.

Votes of thanks to the lecturer and the Chairman concluded the proceedings.

GROWING GRAPES IN NINETY DAYS.

WE have received two letters having an important bearing on this case, and it would appear that more light is still needed. The first is as follows:—"The report which appeared in last week's *Journal* of the paper read by Mr. Gilchrist on "Growing Grapes in Ninety Days," and the discussion thereon, is somewhat incomplete, owing no doubt to Mr. Cowan having to leave in the middle of the discussion. Probably, therefore, the following additional particulars will interest your readers. Mr. Gilchrist said that his employer wished to have Grapes in April, but he was unable to start in November, owing to there being two Vines which were not ready to start in the early house. He closed the house on the 1st of January and applied fire heat, but on the same day the boiler broke down. When it was put in again a tube broke, and altogether he could not get it started till February 6th.

"Then followed the temperatures, &c., which were given in the

Journal. In answer to a number of questions, Mr. Gilchrist said that he attributed his success greatly to disbudding, by which from fourteen to twenty days were gained. The Vine from which the bunch was cut was thirty years old. He thought he could do it again in the same time, but was going to try with pot Vines. He kept his Cinerarias and Camellias in the same house during January. The temperature during that time would be the same as outside with what sun heat could be conserved.

"Mr. Gilchrist was asked for an explanation of the statement made in a paper read before the Society on February 11th, that his Vines were then in bloom. Several members of the Society asserted that they had heard Mr. Gilchrist make this statement. Mr. Gilchrist in reply said that he did not remember making this statement, but if he did say so it must have been a joke. The meeting finally broke up in some disorder owing to the Chairman refusing to put a motion that the discussion be adjourned, and another motion that a vote be taken. The majority of those who took part in the discussion were inclined to doubt the possibility of Grapes being grown in ninety days.—INCREDULOUS."

The second letter is as follows:—"I see Mr. Gilchrist has read a paper on growing Grapes in eighty-eight days before the Sunderland Gardeners' Society. He says he started the house on the 6th of February, and thinned the Grapes on the 28th of March. Now, sir, I saw that he had thinned his Grapes about the end of February, and when up about the middle of March the Vines had finished their first swelling of the berries, so you will see that there is a mistake somewhere.—A LOVER OF FAIR PLAY."

FRUIT FORCING.

Pines.—*Suckers.*—Those recently started should be raised near the glass as soon as roots are plentifully made, so as to secure a sturdy, thoroughly solidified growth, especially in those intended to be wintered in small pots, bringing them on very gradually, and taking particular care not to give a check by withdrawing them from the bottom heat, or only doing so for a short time. When the suckers started this autumn or late in summer become well rooted, transfer the strongest plants to the fruiting pots at once, draining these well. Employ the fibry part only of sound turfy loam, not tearing it up very fine, but using it in lumps proportioned to the size of the pots; the rougher it is, provided it is made compact in potting, the better the plants will thrive. Jamaicas are apt to become weak and attenuated in growth when grown in large pots; 9 or 10-inch pots suffice for them, and they should not be grown away from the glass, nor be kept very moist and close. Queens succeed in 10-inch pots, or very strong plants may be given a little more root space, say 11-inch pots. Envoies have all their requirements as regards soil supplied in 10-inch pots. This is the best variety to grow for sale, the fruit being of a pleasing conical shape, the pips well and evenly swollen, the colour good and bright, and the crown seldom disproportionate to the fruit. Smooth-leaved Cayenne succeeds in 10 or 11-inch pots, and Providence in 11 or 12-inch pots, the advantages as regards time and corresponding size of fruit being in favour of the smaller size, the fruit being proportionate in these respects to the amount of elaborated matter concentrated in the plants whilst growing and afterwards on the fruit. The small plants should be shifted into 7 or 8-inch pots, in which they must be kept until spring. Plunge the plants in a bottom heat of 90° to 95°, in which they must be continued until the roots have taken freely to the fresh compost, when they may be raised, a temperature of 80° being afterwards sufficient.

Growing Stock.—Young plants require free ventilation on all favourable occasions to maintain them in a healthy sturdy condition, maintaining a night temperature of 60° to 65°, with 5° to 10° more by day artificially unless dull and cold, and keep at 80° to 85° from sun heat. Ventilate early in the day, but not so as to lower the temperature, keeping the bottom heat steady at 80°. Water the plants whenever they require it, employing weak and tepid liquid manure. Avoid the use of the syringe too frequently; sprinkling the paths and other surfaces morning and evening will suffice in all but very bright weather. Fruiting plants should have a night temperature of 70°, with 80° to 90° during the day, closing at 85°.

Figs.—*Earliest Forced Trees in Pots.*—Those not in large pots, say over 13-inch, should have the roots examined, and, as it is not advisable to increase the pot, a few inches of soil may be removed from the base of the balls. Loosen these a little at the sides to admit of fresh compost; remove the loose surface soil, shorten the roots, and replace in fresh turfy loam with a sixth of old mortar rubbish and a small handful of bonemeal to a peck of soil, thoroughly incorporated. Afford a good watering, and place the trees where they can have plenty of air with shelter from heavy rains and snow, also safety from frost. Trees in large pots that are stood on brick pedestals to prevent their sinking require different treatment. In their case every particle of old fermenting material—Oak or Beech leaves—should be removed, also all the surface dressing from amongst the roots, with a hand fork. After

shortening the strongest roots and attending to the drainage, apply a surface dressing of the compost named, and ram it firmly into the pots. Supply water to settle the soil, and after this keep the house cool, dry, and well ventilated until the time of starting in November or December. This plan is excellent for trees in 18 or 20-inch pots, as it is not only inadvisable to disturb the roots more than can be helped, but the trees can be assisted by building up turves against the brick piers and laying the roots extending beyond the pots in the loam, so that large trees producing enormous crops of fine fruit may be had without planting them out. To trees not in as large pots as desired, and those requiring an increase of root space, a moderate shift may be given, the sides of the ball being loosened with a hand fork, and any straggling roots cut back, those in the drainage being cut clean away. Drain the pots efficiently, employ the soil in a moderately dry condition of the same kind as previously advised, and ram it as hard as the ball.

Succession Houses.—The trees which are ripening off second crops of fruit require lessened supplies of water, not affording any until the soil is getting dry, and not then if the moisture is sufficient to keep the foliage from becoming limp, for that condition must be avoided. Water must also be withheld from the house, except a sprinkling occasionally during very bright weather, a little fire heat being necessary to admit a free circulation of air and prevent damp. Remove all soft and useless wood, thin out where crowded, and when the fruit is gathered cut away the growths that have reached the extremity of the space and are not necessary for next year's bearing. It is absolutely essential that the wood be thoroughly ripened by the exposure of the growths to light and air, and the points of the shoots on which the first crop next year is borne ought to stand well up or out to the glass and light.

Lifting Unfruitful Trees.—This condition is generally a result of exuberance, and is commonly induced by too large and too rich borders. Lifting sterile Fig trees is a certain means of inducing fruitfulness, and should be performed as soon as the leaves have begun to turn yellow. If the trees are very luxuriant, it is a good plan to make a trench about half the distance from the stem the branches cover of trellis, quite down to the drainage, so as to cut off all roots at the trench. This should be done whilst the leaves are quite green, fully a month in advance of the leaves turning yellow, and it will check the tendency to late growth, concentrate the vital forces on the maturation of the wood and buds, often changing the character of these so that they form Fig buds and produce a good crop of fruit the following year. Carefully lift the trees, cut back any strong and long roots, reserving those which are the most branched and fibrous. Good drainage is of paramount importance, and should not be less than 1 foot thick, with a drain to carry off superfluous water; there is nothing better than brickbats and a thin layer of old mortar rubbish over them. Good turfy loam, preferably off calcareous formations, a sixth of old mortar rubbish, and a similar proportion of road scrapings, form a suitable compost for Figs, and 2 feet depth is ample. Place the soil together firmly in the border so as to insure a sturdy, short-jointed growth, and spread the roots evenly in the top foot of soil, working the soil amongst them, and placing them in layers as they rise, not covering the topmost more than 2 or 3 inches. The compost should be moderately moist when used, and a watering given to settle it about the roots. Keep the house cool and dry. A border of about one-third the width of the trellis, say 4 to 6 feet, is very much better than a wide border, for what is wanted is a sweet calcareous soil firmly put together, yet so friable as to admit of the free percolation of water through consistently with retaining the elements essential to the production of fine Figs.

Peaches and Nectarines.—*Trees Ripening the Fruit in July.*—There are few trees that respond better to lifting and root-pruning than the Peach and Nectarine, and wherever there are cases of bad setting and stoning of the fruit we strongly advise the lifting of the trees when the leaves give indications of falling. If the trees are young, have a tendency to late growth, and do not ripen the wood well, a trench may be made about one-third the height of the branches from the stem, and all roots detached down to the drainage, leaving the trench open for ten days or a fortnight, when it may be filled again and made firm. This concentrates the energies on the ripening and plumping of the wood and buds. Older trees that make strong wood should have the roots wholly or partially lifted and pruned before the leaves have all fallen. Weakly trees, on the other hand, are greatly benefited by the removal of the old soil from over and amongst the roots. Fresh, rather strong loam, with a sixth of old mortar rubbish and about a twentieth part of wood ashes if made from rather large wood, or half that quantity if made from twigs, thoroughly incorporated and made firm, answers in place of the soil removed, following with a good watering of weak liquid manure. It will cause the trees to form fresh roots and invigorate them, being also a good aid in preventing the buds falling. The trees are now approaching the resting period and the foliage is falling, therefore the matter just mentioned must be attended to at once. If the lights have been removed, the trees being in a condition to allow of its being done in August, there will not be any need of water at the roots, but there must not be any lack of a proper supply under fixed roofs, and where the wood is very strong it is not wise to remove the roof lights until the wood is thoroughly ripened.

Trees Ripening the Fruit in August and Early September.—The wood that has borne fruit should be cut out, leaving no more than can be well exposed to light and air. Then cleanse the foliage of dirt, red spider, and brown aphides, by water directed with force from a syringe or garden engine, and repeat occasionally. Scale, however, cannot be so dislodged, and the other pests, especially brown aphids, only partially so;

therefore, apply an insecticide for these infestations. There must not be any lack of moisture at the roots, water being applied as required, and a supply of liquid manure to weakly and heavily cropped trees will help them to perfect the buds and recuperate their wasted energies. The ventilation cannot be too free. If the wood is not maturing well keep the house rather warm by day and throw the ventilators open at night, yet a moist atmosphere must be avoided, as that tends to growth instead of ripening.

Late Houses.—The grandest Peach as regards size, colour, solidity, and quality for late use is unquestionably Rivers' Gladstone, and it is equally as good when grown to ripen early in September as it is at the end of this month or early in October. All the late Peaches require generous treatment and liberal supplies of water through the growing season, with no lack of nutrition when the fruit is taking its last swelling, then there is no want of juice and flavour. If pinched in these respects the fruit may please the eye, but it does not satisfy the palate. When the roots find due supplies of liquid the trees and fruit do not suffer, but a rather drier condition of the atmosphere is beneficial whilst the fruit is ripening. Some soft netting looped up in small pockets to prevent the fruits bruising each other is useful to save any fruit falling through ripeness. An experienced person, by examining the fruit every morning and evening, will generally be able to dispense with the netting, but it is tantalising to lose some of the best fruits, especially when they might have been saved by a net disposed beneath the trees so as to prevent their receiving damage. Thin the shoots where too crowded. Those which have borne fruit should, as soon as the fruit is gathered, be cut out to a successional shoot at the base.

Strawberries in Pots.—The plants must not be neglected for water. Needless supplies seriously injure them by making the soil sodden and sour; yet allowing the foliage to flag is a common cause of the trusses having puny flowers and antherless stamens. When the soil is getting dry and before the foliage flags is the time to supply water. The batches intended for early forcing should be given plenty of room in the sunniest spot at command, and they may shortly be placed in frames, only using the lights in frosty weather and to throw off heavy rains and snow, ventilating freely when the weather is mild. If any plants remain wet for several days without needing water they should have the drainage examined and rectified if defective. Expel worms with lime water. The crowns are numerous in some varieties, a number of small crowns clustering round the central one. The small crowns should be removed sideways with a wedge-like piece of hard wood without injuring the central crown or the leaves. By so doing the vigour of the plant will be concentrated on the main crown, and though the trusses of bloom will be fewer, the fruit will be finer. Keep the surface of the soil rather loose, so as to insure the water passing equally through the ball and moistening it thoroughly. A little dried cow manure rubbed fine applied to the surface of the pots aids root formation, and a little bonemeal, say a pinch between the finger and thumb to each pot occasionally, assists the plumping of the crowns. Remove all runners and weeds, and give the plants plenty of space for the full exposure of the foliage to light and air, so as to secure sturdy growth and well developed crowns, with as much food stored in them as possible.

THE FLOWER GARDEN.

Bulbous Plants.—Any bulbs in a dry state are considerably weakened by being kept out of the ground much later than this, though as far as bedding Hyacinths, Tulips, Narcissi, and Crocuses are concerned they cannot well be planted before the beds are cleared of their summer occupants. In addition to taking an early opportunity of planting miscellaneous bulbs, newly bought in or otherwise, advantage should also be taken of a dry time in September or the early part of October for lifting, dividing, and replanting many of the bulbous plants already established on the place. Not that these require annual or even biennial attention, but most of them pay well for lifting and replanting every third or fourth autumn.

Anemones.—The *apennina*, *nemorosa*, *vernalis*, and *coronaria* types are all perfectly hardy. They are very beautiful in the early spring and summer months, and are simply indispensable where bright coloured flowers are largely required for cutting. They succeed admirably in a variety of positions, including fruit borders. They ought to have the benefit of a freely worked loamy soil to which road grit or sand and well decayed cow or horse manure have been freely added. Dispose the roots $2\frac{1}{2}$ inches deep and about 5 inches apart each way.

Crocuses.—Patches of these in variety are very effective near the fronts of shrubberies and mixed borders, where, if they are planted early and about 4 inches deep, they will increase rapidly, paying well for lifting, dividing, and replanting every third or fourth autumn.

Crown Imperials and Fritillarias.—These ought not to be disturbed often, but if there are signs of failure or it is desirable to increase the stock of any of the varieties, directly their growth is completed lifting, dividing, and replanting may take place. They ought not to be very roughly used, but a small ball of soil and roots should, when possible, be saved with each bulb, the replanting not being long delayed. Mixed borders and the fronts of newly formed shrubberies are the best positions for this class of plants, there being then no necessity for often disturbing them. Any bought in should be obtained and planted not later than October. All require a rather rich loamy soil, those that have been purchased or roughly used being well surrounded with sand. Plant just below the surface in groups of three or six bulbs.

Cyclamens.—Both *C. Coum* and *C. europæum* are comparatively

hardy in the more southern parts of the country, and are admirably adapted for rockwork. The present is a good time for planting them; they ought to have a rather dry sheltered position and a light sandy soil to root in. Plant in groups of about three plants.

Dog's Tooth Violets.—These are more hardy than the foregoing, and are worthy of cultivation for their beautiful leaves alone. They thrive best in a peaty sandy soil, where, if not interfered with, they spread rapidly. The fronts of shrubberies and the margins of beds are the best places for them. If the soil is of a somewhat heavy nature add common peat and sand freely, or failing the former use abundance of good leaf soil.

Hyacinths.—Those permanently planted should not often be disturbed, but when they are moved September and October, or before fresh root action commences, will be the best time to do it. Late in October or early in November is quite soon enough to plant new bulbs in beds or borders. The Grape, Feather, and Musk Hyacinths are of a very different character, and all are very effective in their way. Every four or five years is quite often enough to disturb them, and they ought therefore to be planted rather deeply in front of the borders. They are not particular as to the kind of soil they are planted in.

Iris.—About every third season the bulbous-rooted varieties ought to be lifted, divided, and replanted, taking care not to wholly clear the roots of soil. This may well be done now, and new bulbs planted as soon as they can be had. They all ought to have the benefit of a freely worked well-enriched soil, and if planted somewhat thinly, or about 8 inches apart, and fully 4 inches deep in beds, the surface of the latter during the winter and spring may be furnished with Alpine Auriculas, Pansies, and such like; and during the summer with Verbenas, Mignonette, and other tender plants that do not unduly rob the ground of moisture and fertility.

Narcissi and Daffodils.—These rank among the most serviceable and the most popular spring flowering bulbs that can be grown. To be constantly successful with them they must not be disturbed oftener than every third or fourth year. Single bulbs of choice varieties, given good room and not disturbed, soon surround themselves with offsets, all of which flower grandly when comparatively small, always providing they are not prematurely detached from the parent bulb. It will thus be seen that flower beds are not the proper places for any but the cheap Narcissi of the Polyanthus type; but they will do well near the fronts of mixed borders, shrubberies, and even the open spaces between fruit trees. Commoner Daffodils should also be extensively planted along side paths and drives in woods, and the poeticus type of Narcissi thrive admirably on the banks of ponds and lakes. It may not be advisable to dot them promiscuously over lawns and turf generally, but they thrive well and are very effective when grouped in the turf not far from shrubberies and under high spreading trees. In most cases the tops die down before the grass need be mown, and every season the effect will be greatly improved. From 6 inches to 8 inches apart each way is none too much space to allow all the larger varieties in the various sections, the smaller forms being located about 5 inches apart. Plant to a depth of about 5 or 6 inches. They will thrive in almost any kind of soil, but are most at home in a fairly rich free-working loam, sand or road grit being freely added.

Snowdrops.—These must be planted early, and not often disturbed, or otherwise the stock of bulbs will soon dwindle away. Groups of bulbs 2 inches below the turf on lawns, banks, in shady places, and the margins of lakes, shrubberies, and borders where they are seldom or never disturbed, rarely fail to increase rapidly and flower abundantly.

Tulips.—Any that have long been undisturbed in one place may shortly be lifted and replanted, and new bulbs of border varieties ought to be put out not later than the middle of October. Give them some fresh loamy soil and a little sand to each bulb.

THE BEE-KEEPER.

APIARIAN NOTES.

FEEDING SWARMS.

DURING unfavourable weather swarms should be supplied with a few pounds of sugar reduced to syrup. Use about equal weights of sugar and water; it is better rather thin than approaching a thick state, when it adheres to the bees and injures them. This is a time-honoured practice, and if not carried to excess is a sure means of securing a good return of honey for the little outlay on sugar.

SWARMS.

Swarms always work better than unswarmed stocks, and if they have favourable weather gather more in proportion. The best time for swarms is just when honey is moderately plentiful and about two or three weeks before the great flow, and should be supered at its commencement. As swarms are also liable to swarm in from five to six weeks after their own exodus they require to be watched. If it does not pay in one way to have them watched it is a greater loss to leave them alone.

NON-SWARMERS

In some localities where the honey season is very short non-swarmers are the only ones likely to give good results, but where the honey season is a long one swarms pay best. Besides, the two months in the future are better for swarms to breed and become populous than the six past ones. Old swarmed stocks and second swarms along with the prime one will be in better condition for the Heather than any unswarmed stock, which with its old queen will be a source of annoyance the whole season by its inclination to swarm, which is as often as otherwise its ruin.

NUCLEI.

Owing to the many ways in which they can be profitably turned to account, these must not be neglected. Form them on or about the eighth day after the issue of the prime swarm, by dividing the stock into from six to a dozen, according to its strength. Nuclei are the bee-keepers' bank, which he draws upon for the purpose of superseding an effete one, or by gradually adding the condemned ones' brood combs to it, or by working two queens in one hive. Swarming is prevented, supers are more quickly filled, and the trouble we would have with uncertain queens is avoided; the profit is greater, interest and capital going all to the bee-keeper.

APPLIANCES AT SWARMING.

It may be interesting to mention several indispensables at swarming time, and which are especially useful where hedges and trees abound. To dislodge bees from any inconvenient place where they have hived, or to hasten them entering the hiving apparatus, a long pole or a series of them arranged so as to be easily fastened together, or extension having a brush or some feathers at the extreme end saturated with carbolic acid held beneath the cluster, will cause the bees to ascend the hiver quickly. It will also prevent bees entering chinks, where they would be lost, or difficult to get out.

Another thing I have used for many years is my fruit shaker, which is also a long pole. The hook should be broadish and rounded a little on the inside, so that the bark of the tree or its branch is not injured in any way by its application, whether it be the shaking of bees or of fruit. Steps or light ladders should be at hand in every apiary where there are trees or fences to get over without injuring them.

PRESERVING QUEENS.

Although I have in a previous article recommended tumblers for this purpose, sections filled with comb and partly with honey are, perhaps, preferable. The top and both ends should be covered with one-eighth wood a little broader than the section to form a check for the glass on both sides, and to prevent the possible escape of bees or queen. A piece of queen-excluder zinc the size of the bottom completes the affair.

AFTER SWARMING.

Hives manipulated or divided sooner than the eighth to the tenth day after the first swarm issues suffer greatly through loss of eggs and unsealed larvæ by the bees eating these. This should be kept in mind. After the eight days are up all the royal cells, as well as those of the workers, will be sealed. The former should then be excised and inserted somewhere in the prepared sections—one in each. Place these on the top of the hive, where the bees, induced by the honey, will ascend, and care for the cells and queens after they are hatched. No queen must be allowed to be at large in the hive, or swarming will assuredly take place. The bee-keeper must exercise his judgment how to dispose of these queens, whether they be employed to form into nuclei or preserved to be introduced to stocks after the issuing of the first swarm. But I warn the reader that while this may be successfully accomplished, and the newly introduced queen fertilised and begun to lay, she may be summarily ejected, and probably a drone-laying queen or bee supersede her. It is never safe to introduce a queen to a hive having eggs or larvæ unsealed, especially where queens have been previously under formation. This is the reason so many queens have been lost and hives ruined.

WINTER EKE

or raiser is a very old custom of wintering bees in Scotland—not very long adopted in England, and but lately in America. The eke, as used in Scotland, was shallow, and the entrance kept narrow; but the modern bee-keepers give a wide entrance, to prevent dead bees completely blocking up the entrance, and to cause a draught to keep the combs dry. This is quite plausible theoretically, but very faulty practically, which I discovered with my first trial many years ago. During our humid weather in winter hives with much doorway admit a great deal of moisture,

which moulds the combs and pollen, turns the honey to vinegar, causes the bees through the unnecessarily low temperature and spoiled food to become unhealthy, and if the cold is protracted to die. The contrast to the above-mentioned hives, which I have seen, is so great that the owners of them have resolved they will not be misled by "modern ideas" again.—A LANARKSHIRE BEE-KEEPER.

TRADE CATALOGUES RECEIVED.

Messrs. J. Cheal & Sons, Lowfield Nurseries, Crawley.—*Trees, Shrubs, Fruit Trees, Roses, &c.*

Mr. G. Chaundy, William Street, New Marston, near Oxford.—*Carnations and Picotees.*

Mr. H. Geggie, Bury, Lancashire.—*Carnations, Picotees, Pyrethrums and Primulas.*

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Vegetables at Frogmore (E. B.).—You are not to be blamed for failing to understand the sentence on page 230 last week:—"11 acres are devoted to Potatoes, Asparagus, Seakale; and even Horseradish are grown by the acre." The printers did not exercise their usual care in following editorial instructions. The sentence should read:—"11 acres are devoted to Potatoes. Asparagus, Seakale, and even Horseradish are grown by the acre."

Seedling Carnation (J. L.).—It is an attractive yellow ground. There are now many of this class, some of which it resembles. You might send a few blooms to Mr. Turner at Slough, and ask him if it is distinct from those in his large collection. If of no special value as a florist's flower it is well worth keeping as a garden variety.

Tomatoes not Setting their Fruit (H. P.).—The flowers are very defective, and their condition is probably occasioned by the excessive vigour of the plants, which is unfavourable to fruit production. The only things we can suggest are to keep the house drier, curtail the leafage, so as to concentrate the vigour more on the trusses, ventilate freely, and fertilise the flowers when they are fully expanded and the pollen is ripe.

Ventilating Vinery (B. S.).—It would not be safe to shut the house up close at night whilst a number of Grapes are hanging on the Vines and the structure filled with plants. The moisture arising from the latter would cause the Grapes to decay. Keep just a little warmth in the pipes, and leave the ventilators open an inch or two all night, and so maintain a dry, buoyant atmosphere; a high temperature, however, must be avoided. Water the plants in the morning, so that all moisture can be dried up before night.

Planting a Slope (Gardener).—The material forming the slope being stiff clay it will not answer to make large holes in it for planting the shrubs, as they will only become receptacles for holding water; or if the soil is so porous as to allow the water to escape there will only be the good soil in the holes for the shrubs to grow in, and they will languish in a year or two after planting. We have tried the plan and found it fail. The best plan would be to mix some ashes with the clay to the depth of a foot, which will improve its texture, and then cover the whole of the slope with a foot or 18 inches depth of good soil. Common Laurels pegged down might be the most suitable. Rhododendrons would not suit the position, and it is doubtful if the soil would be adapted for them.

Corypha australis Wintering Outdoors (J. D.).—We have known large plants of this species to winter safely in a dry shed with the tubs in which they were grown surrounded and covered with dry straw and the heads wrapped in mats during severe weather, but the leaves were more or less disfigured, quite as much if not more by the putting on and removal of the mats as by the cold. It did not succeed outdoors, even when planted out, and the roots covered as well as protected over the head in frosty weather, but the situation was rather damp, and success is more likely to be assured in a dry and sheltered situation with efficient covering in severe weather. We can, however

hold out little hope of its proving hardy enough to withstand an ordinary winter, and certainly not a severe one, with a single or even double thickness of mats wrapped around it.

Use of Tomato House in Winter (S. S.).—As you wish to start the Tomato plants so as to produce ripe fruit by the end of April or early in May, it will be necessary to raise plants from seed not later than the New Year; but plants from cuttings struck about this time, and wintered in small pots well up to the glass, are better for early supplies than plants from seeds. Roses in pots are hardly likely to pay for firing to have the plants in flower at Christmas, unless they are now advanced in bud, and would only require a genial warmth to bring them into flower. Chrysanthemums for specimen blooms would be the most likely plants, as we fear the pipes are so arranged that Mushroom beds could not well be made; but what we take for hot-water pipes on your not very clear plan may be ventilators, as you mention them at the bottom of the ends. If there is room we advise your growing Mushrooms, making up the beds at once, and they will produce well at midwinter. We presume you have another structure in which the Tomato plants can be forwarded.

Black Hamburgh Grapes not Colouring (F. J.).—The chief cause of Grapes not colouring well is overcropping. That we think is your case, as the Vines are perfectly healthy and have not been infested with insects or mildew. The removal of a large quantity of foliage at one time, or allowing more to be made than can have full exposure to light, and then having to thin it so as to admit a fair amount of light and air, is sufficient to account for the defects in colouring. Ample supplies of nourishment at the roots are of little use unless the Vines have plenty of foliage, so disposed as to elaborate it. Though Black Grapes colour better under a good spread of foliage the Vines must not be allowed to become crowded with spray, so as to hinder the principal leaves from performing their functions, but should be kept well in hand by judicious pinching. This has perhaps been neglected in your case, and we fear little can now be done as the season is so far advanced, but we should keep the temperature 5° less at night, so as to give the Vines some rest, admitting air early in the day with a little at night as at present.

Thermometer Scale (Learner).—Fahrenheit's is used chiefly in Britain, Holland, and North America, the freezing point of water on which is at 32°; and the boiling point, 212°. Reaumur's thermometer was that chiefly used in France before the Revolution, and is that now generally used in Spain, and in some other continental States. In its scale the freezing point is 0°; and the boiling point 80°. On Celsius or the Centigrade thermometer, now used throughout France and in the northern kingdoms of Europe, the freezing point is 0°; and the boiling point 100°. Hence, to reduce degrees of temperature of the Centigrade thermometer and of that of Reaumur to degrees of Fahrenheit's scale, and conversely:—Rule 1, Multiply the Centigrade degrees by 9, and divide the product by 5; or multiply the degrees of Reaumur by 9, and divide by 4; then add 32 to the quotient in either case, and the sum is the degrees of temperature of Fahrenheit's scale. Rule 2, From the number of degrees on Fahrenheit's scale subtract 32; multiply the remainder by 5 for Centigrade degrees, or by 4 for those of Reaumur's scale, and the product, in either case, being divided by 9, will give the temperature required according to Fahrenheit's.

Orchids from Trinidad (S. K.).—The names of the Orchids which you have received from Trinidad are by no means clear. When they bloom, a few flowers and a leaf should be sent to the office, so that the right names may be given. Judging from the information in your letter we should say that the plants are (1) *Oncidium citrinum*, which has citron-coloured flowers, borne on racemes a foot long; it flowers in the spring, and was introduced from Central America in 1848. (2) *Oncidium Baueri*, which has long pseudo-bulbs and leaves, and bears long panicle spikes of yellow flowers. This and the foregoing should be potted in peat and sphagnum, and always kept moist. They require an intermediate temperature. (3) *Oncidium Lanceanum*, which, when in good condition, is a valuable plant. It has long leaves and erect spikes of large beautifully scented flowers, dull yellow marked with chocolate; the lip is a pale violet colour. This plant requires a stove temperature, and when growth has finished may be kept rather dry until started again. It should be grown in baskets suspended near the glass. (4) *Rodriguezia secunda*, which is a native of Trinidad, and should be grown in baskets, in peat and sphagnum, in a stove temperature; it must be kept moist, and in the autumn should produce spikes about 8 inches long, carrying many small deep rose-coloured flowers.

Names of Fruits.—Notice.—Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (P. & Sons).—We cannot attempt to name the Apple with confidence, all the specimens being more or less distorted. (R. C. L.).—3, Apparently a nameless local Apple. 4, Duchess of Oldenburg. 5, Golden Spire. We do not undertake to name Plums unless portions of summer shoots are sent with them, as has been stated before. (G. W.).

—The Apple is Cellini; the purple Plum Cooper's Large, and the other Washington. (C. F. H.).—1, Emperor Alexander; 2, Bedfordshire Foundling; 3, Early Julian. Some specimens received as we are preparing for press will be named next week.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (A. J. L.).—*Eurya latifolia variegata*; it would probably succeed under the conditions indicated in your locality.—A correspondent sends a small box containing one specimen with a yellow flower, packed in moss. There is no letter, and the post mark is illegible. The specimen is *Cassia corymbosa*, figured on page 233 of last week's issue.

COVENT GARDEN MARKET.—SEPTEMBER 21ST.

MARKET very flat indeed, with prices much depressed.

AGRICULTURAL REFORM.

HERE is the title of our article, for whatever it may be worth; but as it was written the thought occurred, "Would not estate reform be more to the purpose?" The gravity of the situation deepens in intensity for those farmers who cling to Wheat and stock, no profit, but actual loss, being the record of most of them. "Whatever shall us do now, then?" was the

exclamation of a worthy old farmer last spring when the prices offered for his store cattle were less than he had given for them a year before. What to do, and how to do it, is the enigma in farming which many a man fails to solve at all, and yet the way to achieve successful reform seems plain enough.

Landlords generally have reduced rents very much. Unfortunately this has not been a voluntary concession, but it has been done under a threat to leave, actual notice, or bankruptcy of tenants. There has been very little of graceful concession on the one hand, and grateful acceptance on the other. A lamentable feeling of antagonism has grown up, not altogether from hard times, but from hard measures and injudicious treatment, even in the good times. Then rents went up because tenants were so prosperous, and a host of applicants were after every vacant farm. They subsequently fell with the price of Wheat, till many a farm has been let for half, or even two-thirds, the rent that it made twelve or fourteen years ago. If with such reductions there had been an equally radical and sensible change in the farmer's management of his affairs, farms everywhere ought still to answer.

One of the pioneers in the immigration of northern farmers to Essex has said distinctly that there is great room for improvement with a large proportion of farmers. Thrift, combined with energetic action, the presence of the master's hand and eye being felt everywhere and in everything on the farm, is necessary. He tells of a large farm in hand on which two tenants had become bankrupt. A Scotchman hired it at a reduction of 25 per cent. on the former rent. His failure was confidently predicted by his new neighbours. On the contrary, he made 8 per cent. interest on his money the first year, and from 12 to 15 per cent. per annum upwards; but then he reduced the arable area from 350 acres to 90 by laying down the remainder to temporary pasture. Instead of the fourteen men formerly in constant employment upon the farm, six men, with two lads and two women, were sufficient except for the haymaking and harvest. The Wheat acreage was reduced from 100 acres to 10 or 15 acres, and the number of horses from twenty-one to six. A dairy of seventy cows was started, bare fallowing was done away with, the land was kept clean by roots, or by growing heavy crops to smother the weeds. The reform proved entirely successful, owing, as the report sets forth, to "a more energetic handling of workmen and better planning of work, while the judicious change in the style of farming rendered fewer men and horses necessary."

Said another able farmer "I farm to live, and live I will. I get a profit, and intend doing so. What grieves me is that I cannot do it in the old style." The books at this farm show an annual curtailment in expenditure upon rent, rates, labour, feeding stuffs, and manures of £1357 12s. 9d. as compared with what was spent—and spent profitably too—twenty years ago. This was a midland farmer who wisely resolved to face the situation and stick to his farm; he was able to do so by a reduction of nearly £350 in rent and rates, and his own energetic action in changing his method of farming.

When the depression had got agriculture thoroughly in its grip Essex was the county which suffered most. Hundreds of corn farms became vacant there, and land fell so much in value that it could be bought outright for £10 or £12 an acre. But now it is turned to by northern farmers as a veritable Land of Goshen, where profitable farming is yet possible. How this is so we have shown. Last year, we are told, nearly a hundred more Scotch farmers went with their Ayrshire milkers, and their great broad-chested, raw-boned laddies to seek their fortunes in Essex. Some East Lancashire farmers have been established there in farms for some time, and we now hear of others who contemplate leaving high rented farms in North and West Lancashire for Essex farms, which can be had at 14s. or 15s. per acre tithe free. Of the Lancashire farmers who settled in

Essex three years ago it is said that though none of them have made their fortunes, they have proved migration to be an experiment worth trying. It may be so, but much depends upon the farmers as well as upon land and rents. In a "manifesto" just issued on behalf of the Lancashire Tenant Farmers' Association from the central offices at Preston, they say "We are, and have been for some time, suffering from difficulties which can be removed by reasonable concessions on the part of the landowners and their agents, and by ameliorative legislation." Landlords and the legislature may very naturally in turn ask, And what have you done, what are you doing yourselves to meet the difficulty? Is the dairy farming in Lancashire still managed in the old way? Is there any real improvement in the management of dairies, pasture, or cows? Is the average milk yield what it should be, or is there any real effort at improvement in the selection or breeding of cows?

WORK ON THE HOME FARM.

A recent journey northwards enabled us to see that most of the corn was carted south of Northampton, and much of it is now in stack even in the north midlands. Many of the stubbles seemed exceptionally clean. Ploughs were at work on some, but nothing like brisk systematic autumn tillage was visible anywhere on the land. Yet the weather has been most favourable for such work, and we greatly regret that it is not more generally turned to account. Most of the Wheat has been carted in excellent condition. Some of the Barley has lost colour from heavy rain, but good samples are certain to be plentiful, with some decline in price when the season is in full swing once more. Bean stubbles have been very foul with weeds, the crop of Beans is inferior in yield, and the plant was so thin that it is practically a failure. Weeds became rampant after the growth of the Beans was so high that hoeing was out of the question. There is no doubt that thick seeding to smother weeds is sound practice. Thin seeding and repeated hoeings were all very well when Wheat sold at 50s. per quarter, but it will not answer now with Wheat at 30s. or considerably less.

We have much land now in course of preparation for fruit farming, so as to be ready for the planting early in September. Some small plots are being drained and trenched; others extending over several acres are being broken up by the steam cultivator, which does the work thoroughly, and at a much cheaper rate than the trenching. No manure has been used, but before the planting a surface dressing of muriate of potash, bone flour, and superphosphate will be applied to the entire surface and be worked in with planting tools where plantations are being made; for orchard trees the manure will be worked into the stations. This is much cheaper, and far more efficient than farmyard or stable manure, which is so expensive to cart, and is often of doubtful benefit. The use of manure at all in planting depends altogether upon the condition of the land. Sound fertile soil needs no manure at the planting, an excess of stimulants inducing rampant growth, which ripens badly, and is not satisfactory.

It is obvious that judgment and caution are required in this work if the best results are to be had. Among these quick returns are certainly a prominent factor; they can only be had by careful preparation, timely and judicious planting, and subsequent skilful management.

REMARKS.

- 11th.—Generally overcast, but occasional gleams of sun.
 12th.—Overcast morning; sunny afternoon, with solar halo.
 13th.—Generally overcast, with occasional gleams of sun in morning; hot sun in afternoon.
 14th.—Clear sunny morning; occasional cloud in afternoon, bright night.
 15th.—Overcast early; almost continuous bright sunshine after 9 A.M.
 16th.—Frequent sunshine in morning; rain about 1.30 P.M., bright sunshine after 2.30 P.M.
 17th.—Cloudless almost throughout.
 An almost rainless week, with much bright sunshine. Temperature above the average.—G. J. SYMONS.

THE SUCCESSFUL MANAGEMENT OF APRICOTS.

IT is not often that we see a house of Apricots. The reason is not that the ripe fruit is not esteemed for dessert, as when thoroughly ripe, the skin slightly cracked and shrivelled, the Apricot is not only one of the most beautiful but one of the richest fruits in the world. Imported fruit is as indifferent in quality as it is uninviting in appearance; fruit from walls is too late to compete with foreign produce, and it is often not half-ripe or even half-coloured on one side when gathered. Fruit in a half-ripe condition does not impress the palate very favourably, and it is one characteristic of the Apricot that it will not ripen after being gathered in the early stages of ripening under any circumstances so as to have a fourth of the richness and flavour of fruit perfectly matured on the tree, indeed Apricot culture outdoors is, in nine cases out of ten, a pronounced failure. This is not because the Apricot is more tender than it was, nor through the assumed decrease in temperature of the seasons, for that is not borne out by the meteorological observations, but it is partly a consequence of the indifferent management of the trees now compared with that formerly bestowed on them and other fruit trees grown against walls, especially as regards protection to the blossom, incipient fruit, and tender growths. It is also partly due to the suicidal persistence in growing varieties unsuited to the climate. The variety Moorpark, one of the best, if not the best Apricot, is a complete wreck under precisely the same conditions as those in which Blenheim or Shipley's is perfectly healthy. Some of the varieties of Moorpark, such as Early Moorpark, Hemskerk, and Powell's Late, are hardier than the type, yet none of them equals it in the quality of the fruit. Kaisha is a model of growth, health, and fruitfulness in Apricots. It grows about half as much as Moorpark. That variety is far less vigorous than Royal and Blenheim, yet these are much hardier, and so is St. Ambroise, which is a good grower and fruitful, than the Moorpark race. The Peach or Grosse Pêche Apricot closely resembles the Moorpark in its fruit, but is distinct in its foliage and habit from that variety. If anything, its fruit is larger, more rich and juicy, and it is quite as tender as the Moorpark. Oullins Early Peach is hardier and earlier than the type, and a very desirable Apricot. Large Early Montgamet is not liable to gum, and its fruit is large, firm in the flesh, yet juicy and good, and ripens early. New Large Early (Rivers) has earliness and rich flavour to recommend it, and is no doubt the best of the Apricots for growing under glass for early fruit. Then we have Frogmore Early, small in fruit, and of good flavour, the tree very prolific, and ripening its fruit first of the Apricots. There is still the Breda Apricot, hardiest of all, but its fruit is small, and only of use for preserving; the tree is healthy and a good bearer.

Such are the varieties of Apricots in a general review of their characteristics and merits. Those that do not succeed outdoors are the best indoors; they leave their weaknesses behind them, and after becoming thoroughly established under glass, which it does not take long to effect, for the Apricot is a free grower and commences to bear in a very young state, produce fruit abundantly of the highest excellence, far superior to that produced by trees trained to walls. Moreover, there is a great difference between choice fruit produced under glass and that imported—a difference in favour of the former. All the varieties are not worthy of cultivation under glass. New Large Early, Early Moorpark,

Oullins Early Peach, Moorpark, Peach, and Powell's Late comprise half a dozen of the best for a cool house, or for one with sufficient artificial heat to exclude frost. New Large Early, Early Moorpark or Oullins Early, Moorpark or Peach, furnish the best three or five for forcing. Kaisha is an amateur's Apricot, good everywhere alike, and only requiring about half as much space as the others named. Success is certain, either with trees planted out in properly prepared borders or with those grown in pots, if the essential cultural conditions are complied with, and it is as well to bear in mind that the most abundant crops are grown in Northern Africa on the borders of deserts too sandy in soil and too dry in atmosphere for the production of many fruits. It is of no use attempting to grow Apricots with the stewing treatment given to Vines or even Peaches, for the trees delight in a sunny day and a cold night, and show their dislike of a close, warm, moist atmosphere by casting the blossoms instead of setting the fruit, and those that pass this stage may be cast instead of stoning when the size of pickling Walnuts. The Apricot loves fresh air as much as a Bedouin of the desert, and must have it in every stage of growth. For that reason we find it succeeding in orchard houses with boarded sides that let air in through the openings between the boards when the house is closed, whilst there is a signal failure in one with solid sides and close-fitting lights and panes of glass. It is, therefore, a question of air with just sufficient warmth to prevent damage from cold that marks the line of demarcation between failure and success in Apricot culture under glass.

The house for forcing (and all culture under glass is forcing) should be light and ventilated both at the top and bottom, and efficiently heated, plenty of piping being provided so that the heat is not radiated at a high temperature. By efficient ventilation I mean lights to open the whole length of the house, not one here and there in the roof, and similar provision at the front or at the sides, but full provision for perfect ventilation. There is no objection to boarded sides if ventilators are provided to open the whole length of the house, and on both sides of a span. The trees may be trained to a trellis fixed 12 inches from the glass. A lean-to, facing south, may be 10 to 12 feet wide, and is the best for early forcing. The trees should be planted in front and trained so as to occupy the whole of the roof, for trees against the back wall produce little beyond leaves. When a house is erected over trees against a wall it is necessary to only allow the front trees to extend so far up the roof that the sun at midday will shine right down to the base of the trees on the back wall. A span-roofed house is not good for forcing unless the ends are placed north-east and south-west, and then it is not equal to a lean-to for early work, but it is better for later crops. A span-roof 18 feet wide will accommodate trees on each side, and standard trees bear just as well as those trained to trellises, while with the heads well up to the glass and plenty of light sideways they furnish about twice as much fruit as those on the stereotyped trellis system. Two rows of 4-inch hot-water pipes answer for the lean-to, and two rows on each side for the span.

The borders should be wholly inside and not made all at once. A 4-feet width of border, or such width as will admit of the roots being spread out straight, with about 1 foot more for their extension, is ample to commence with. It should be drained 9 inches to a foot deep, and have a drain below all to carry off superfluous water. The drainage should be covered with a 3-inch layer of old mortar rubbish or chalk; if neither of these can be had use some burned bricks or soft sandstone, preferably red. From 24 to 27 inches depth of soil is ample. Apricots require a silico-calcareous soil. A calcareous soil interspersed with flints, as occurs in many parts of Hertfordshire, is the soil of soils for Apricots. It also succeeds on the calcareo-silicious soils of Oxfordshire and the ferruginous gravels and sands of many districts, especially on the new red sandstone. Apricots do not seem to thrive in argillo-calcareous soil outdoors, especially when the substratum is clay;

but indoors this is a capital soil for Apricots and fruit trees generally. Good turfy loam, neither light nor heavy, but preferably calcareous and silicious than heavy, four parts, lime rubbish from an old building one part, and road scrapings one part, the loam chopped moderately small and fine, the whole well incorporated, form a suitable compost. It should be made compact, and the trees may be planted as soon as the leaves begin falling. Those that have been trained to walls for about three years are the most suitable, as they will be in a fruitful state and calculated to afford a moderate crop of fruit the first season, and having been lifted annually they can be moved with safety. The borders being firm and a few inches allowed for settling, plant at once, giving a good watering. If the roof lights are moveable, as they ought to be, take them off and mulch over the roots with a couple of inches thickness of short stable litter, but not containing more than a third of manure.

Apricots succeed well grown in pots. As a rule, striving to grow them in a house with other fruits is not successful, yet I have seen them produce some fruit in a house with Peaches and Vines. Trees should now be procured or ordered. Standard trees are much the best. By standard is meant a tree with a clear stem and a rounded head, the height of stem being proportioned to the space or height of the house. Bushes answer for low houses, while pyramids are better adapted for houses of medium height, as spans. If in pots when received they must be given a size larger if they require it whilst the leaves are on the trees, disentangling the roots at the sides of the ball with a fork, and cutting back any straggling or thick ones. Drain the pots thoroughly and ram the soil firmly, leaving space proportionate to the size of the pots for holding water and top-dressings. Trees that do not require a shift need only have the drainage rectified and be surface dressed, or the old drainage may be cleared away, a few inches from the base removed, the roots shortened back, and fresh drainage and soil given, using good fibrous loam, old mortar rubbish, and road scrapings, as advised for the borders, with a fifth part of well-decayed manure and a pint per bushel of Thomas' phosphate powder, removing also the loose surface soil and supplying rich material. If the trees are not in pots, bushes or pyramids should be lifted when the leaves commence falling, have their roots trimmed, and be potted firmly, allowing them to become established in the pots before subjecting them to forcing. The trees should be stood on a hard bottom, impervious to worms, and surrounded with ashes to the rim, covering the pots with litter upon the approach of frost. If the growths are not well ripened the heads should be protected in severe weather, or they may be wintered in an orchard house, in which they should be grown in preparation for forcing. The trees should have a good watering after potting or having the roots interfered with.—G. A.

THOUGHTS ON TOMATOES.

I HAVE been much interested in the recent notes on Tomatoes which have appeared in your columns. Year by year some of the newer varieties are grown alongside of true and tested friends, and subsequently retained or discarded. This year nearly half my plants were Challenger, both in houses and outside. I am very well satisfied with this Tomato, and consider it a real acquisition. It is a strong grower and free fruiter, and I found it very good indeed for pot culture. I think that I found it the best of all for pots, although Chemin (a French variety) ran it close, and was indeed in many plants indistinguishable from Challenger, yet the latter has beaten the other varieties in weight of produce. Alluding to the similarity of these two, I may say that I sold plants to a gardener of each, and he afterwards complained that I had only supplied him with one, and he wanted to know whether it was Chemin or Challenger. Growing them side by side I also failed to perceive any difference in some plants; the fruit of Chemin is on some plants flatter, whereas in many cases it is exactly similar to Challenger. I grew Chemin last year from seed supplied by Messrs. Vilmorin, Andrieux & Co., and was well satisfied with it, and those raised this year were from the same packet of seed. The growth of the two varieties is also similar.

Prelude, I see, is described by Mr. G. M'Dougall as of two colours, and I may state that although I have always saved seed from the red I have occasionally found a plant with pink fruit. The same thing has occurred with other varieties. With great regret I have determined to discard Prelude. A better setter and cropper I never knew, but the weight off each plant did not realise as great a profit as in the case of others. If Mr. M'Dougall has secured a cross with a larger variety (preferably a good type of the Old Red), I have no doubt it will turn out a success. I think it was last year that I advocated this cross in your columns.

Ponderosa, I see, was submitted to the Fruit Committee by Mr. R. Owen of Maidenhead, but was passed on account of its "dingy crimson" colour. I grew this variety last year and found several plants carrying red fruit, so I saved the seed of some, and this year, with the exception of two plants, all bore red fruit. I have taken the liberty to send Mr. Owen a medium-sized fruit. I do not know what his experience of it is as a cropper, but I have this year found it far freer in fruiting than last year, and the weight of produce has made it profitable. Earlier in the season I had plenty of fruits weighing 12 and 14 ozs. each. In the United States I see Messrs. Henderson of New York (from whom I obtained the seed) have in their seed list letters from correspondents mentioning such weights as from 2 lbs. to 3 lbs. for a single fruit. I have no doubt very heavy fruits could be grown here, but my aim is for medium-sized fruit, five or six to the pound, which I find far more saleable. A Guernsey market variety which is dwarf in growth and fruitful I find as profitable as most, but too many of the fruits are ill-shaped.

I forgot to mention that Challenger does not succeed outdoors with me in one very important particular. Nearly every fruit cracks round the top and decay soon commences. Had it not been for this I should have found it a suitable variety, for it fruits freely.

Early Ruby, an American variety, I find to be exceedingly useful both outside and in. It is early, carries a heavy crop of medium-sized fruit, and is also a very moderate grower, so that a more desirable variety for outdoor work and unheated houses I do not know. I have a narrow lean-to with a west aspect planted with this Tomato, and the fruit hangs in regular ropes. Outside also it is carrying a heavy crop. This and Laxton's Open Air I find to be the only two varieties that I can always depend upon to carry a crop outside. It is risky to depend upon any others entirely, although I never fail to try a few other varieties. Early Ruby must not be confounded with Holborn Ruby, which I do not know, and it is not ruby coloured but red, for which reason I think a more desirable name might have been found.—H. S. EASTY.

ODONTOGLOSSUM BICTONENSE.

THIS old Odonoglossum is not very frequently met with, but is well worthy of a place on account of its period of blooming, its free flowering, and the attractive appearance of the flowers. These vary somewhat in colour; a form now blooming in Messrs. Laing's nursery (where the Orchids are in admirable condition) has the triangular lip almost pure white, and the sepals and petals light brown, or so thickly dotted with brown as to hide any ground colour there may be. But in all its forms it is a graceful and pleasing little plant.

RODRIGUEZIA SECUNDA.

FEW Orchids are more easily grown than this, and as it can be readily imported in good condition it is also a cheap plant. It is very dwarf, growing from 6 to 8 inches high. The spikes are slightly pendulous, and the flowers are produced throughout September, thus making the plant a welcome addition to the Orchid house when flowers are somewhat scarce. It was introduced from Trinidad in 1820. The genus was named in honour of Emanuel Rodriguez, an eminent Spanish botanist and chemist. The pseudobulbs are oval in shape, and short; the leaves lanceolate, leathery, keeled; the spikes are about 8 inches long, and carry fifteen to twenty dark rose-coloured flowers. Although arranged on each side of the rachis, the flowers all rise to the upper side, and open at the same level. The petals are ovate, obtuse, and the lip is slightly reflexed. If grown in baskets, in peat and sphagnum, and suspended near the glass in a stove temperature, given plenty of moisture while growing, and never allowed to get quite dry, it will flourish.

Mealy bug has a liking for the axils of the leaves, and should never be allowed to establish itself. *R. secunda* may be grown in an intermediate temperature, but it does not flower so freely as in a warmer house.—C. K.

CATTLEYA STATTERIANA.

LOVERS of Cattleyas would hold themselves particularly fortunate in the introduction or exhibition of fresh and beautiful forms were all of these at their command on reasonable terms, but this is not always so, and it is markedly the reverse in the case of the magni-

its characters point to a hybrid origin, and, as intimated in the reference to it last week, it is more than likely that it is a natural hybrid resulting from the crossing of *C. gigas* and *C. aurea*. There is nothing in the whole collection of fine Cattleyas now possessed to excel it in size, beauty of form, or rich colouring. In the latter respect it is conspicuously distinct. The apical area of the lip is rich velvety crimson, and purplish streaks radiate from it into the throat. The side lobes are deeply coloured with the rich nankeen yellow of *C. aurea*, approaching to orange. There is a suffusion of carmine on the outer surface of the tube, and along the whole of

FIG. 38.—CATTLEYA STATTERIANA.

ficent hybrid exhibited by Mr. Johnson, gardener to T. Statter, Esq., Stand Hall, Manchester, at the last meeting of the Royal Horticultural Society under the name of *C. Statteriana*. There is little doubt that, so far as Great Britain is concerned, Mr. Statter can claim an absolutely unique possession in this remarkable form, and as his great object is to secure a collection of special interest, it is hardly likely that he will allow so striking a plant to leave it for any financial consideration, though tempting offers would, no doubt, be made were it for sale.

We have referred to *C. Statteriana* as a hybrid. There is no definite and precise knowledge that such is the case, for the plant was an imported piece, and there is no history about it to give, but

the edge of the flower runs a feathering of rosy carmine, recalling a heavy-edge Picotee. The sepals are ivory deepening to lemon, and the petals, which are broad but much recurved, are pure white.

The flower is also effective both in size and form. It is a star of the first magnitude. The tube is somewhat short and is not closely folded. The lip is very long and broad, rounded near the throat, flattening and curving down towards the apex, but the tip is elevated and, like the petals, beautifully fimbriated. Considered in relation to no special feature, but as a whole, this noble Cattleya has a dignity and charm that command the deepest admiration. Fig. 38 represents it.

ONCIDIUM INCURVUM.

THIS beautiful Mexican Orchid was exhibited in good form by Messrs Pitcher & Manda of Hextable on September 6th at the Drill Hall. Few Orchids are more easily grown than this, as a cool house will suit it the whole year round. The pseudo-bulbs are ovate and ribbed, the leaves stiff and bright green. The paniced racemes are 2 to 4 feet long, bearing hundreds of small flowers; the sepals and petals are wavy, and banded with white and purple, while the roundish lip is pure white. The plants grow freely, and should be potted firmly in peat and sphagnum. A well-grown plant in a 24-sized pot will bear six to ten racemes, which bend gracefully, and greatly enhance the beauty of the Orchid house in autumn and winter.—C. K.

CYPRIPEDIUM PARISHI.

SEVERAL plants of this interesting Ladies' Slipper were exhibited at the Drill Hall, Westminster, on September 20th. It is a native of Moulmein, and should be grown in the East Indian house in fibrous peat and loam, with a little chopped sphagnum. The plant was originally discovered by the Rev. C. Parish in 1859, but it was not until 1868 that living plants were first introduced. Messrs. Low & Co., Clapton, have the honour of being the first to import it alive. The leaves are distichous, leathery, and bright green. The flower scapes, which bear from three to six flowers, are slightly arched by the weight of the blooms. The dorsal sepal is greenish yellow, the lower one smaller, but the same colour. The petals are drooping and much twisted, 4 to 5 inches long; the basal half green, the upper half purplish; the lip deep green, stained with purple.—C. K.

RESTREPIA DENTATA.

A VERY distinct little species which has flowered in the Glanvin Botanic Garden on several occasions, and been sent to Kew for determination. It has a very marked peculiarity in the presence of a pair of slender, stipule-like teeth on the petals, one on either side, about the middle of the lanceolate basal portion, and these are decurrent below their free apex. The dorsal sepal and petals are semi-transparent white with three purple lines, the decurrent teeth of the latter being yellow. The lateral sepals are dull yellow, nerved with brownish purple below, and the lip brownish purple, with the falcate side lobes deep yellow. Mr. Moore is unable to state its native country, though in all probability it comes from some part of the Andes.—("Kew Bulletin.")

ASPASIA BARCLAYI.

A SMALL species sent to Kew for determination by W. L. Barclay, Esq., The Briars, Reigate, in July, 1891. It is allied to *A. Principissa*, *Rehb. f.*, and *A. psittacina*, *Rehb. f.*, though its flowers are much smaller and otherwise different. The sepals and petals are of a very pale yellowish green with broad transverse light olive-green bands, and the lip white with some nearly confluent light purple markings in front of and beside the keels, and a pair of small yellow markings at the extreme base. In addition to the two central keels there are three or four obscure radiating ones on either side at the extreme base of the lip. Its habitat is not recorded.—("Kew Bulletin.")

JUDGING HERBACEOUS FLOWERS.

AS one who has for many years, long before the taste for them had been so developed as it happily is now, cultivated as far as his limited space would allow this most attractive and useful class of plants, and who has done his best to encourage this taste, and for that reason probably has been called upon to adjudicate upon them at many of our shows, the discussion originated by my friend the Rev. Lionel Garnett has had a peculiar interest for me, and I can give my testimony to the many difficulties that surround the subject. As your correspondent has appealed for opinions on it, I willingly add my mite to those which have already been given.

And first as to the question, What is an herbaceous plant? I remember the advice given to me by that master of logic, Archbishop Whateley, Avoid definitions. The wisdom of that is shown in this very subject, for I have not seen any definition of them that would not exclude some class or other amongst them. Some have said that they are plants which die down and come up again in the spring, but there are many of our most beautiful plants which remain above ground all the year. There are again others who think it ought not to include the Lilies or any other bulbous plants but while an exact definition might exclude these it would imply, I think, a great loss to our stands of herbaceous plants, of which they oftentimes form a very striking feature. There are many of our plants which are only biennials, but which are truly herbaceous,

though not herbaceous perennials, and it would be a great pity to exclude them from the stands. Is there, then, no limit to be placed on the plants which are to be set up? Yes, I think that all shrubby or hardwooded plants should be excluded. Hydrangeas or shrubby Spireas for example ought not to be admissible; one might as soon, I think, put up a bunch of single Roses.

As to what ought to be shown on a stand it seems to me that a few things should be clearly defined. In the first place it should be distinctly stated that all plants should be grown in the open air. It is not sufficient to say that they are hardy. I remember once seeing *Lilium auratum* shown at Manchester at the end of May. Now of course it is hardy; but the bloom exhibited must have been from a plant grown under glass, and this is not what is meant by a hardy plant. Many plants, too, are hardy in one part of England which are not in another, and therefore many might be surprised to find what are called hardy in a district with which they are unacquainted. I think then that it should be distinctly stated that all cut flowers in this class must be from the open air. It is different with Alpines. These are often grown in pots or pans; but as they are only shown at a few early shows it is unnecessary to say much upon them; they are never shown as cut flowers.

If I had my way I should always exclude all florists' flowers (as people now call them), from a stand—I mean such flowers as Phloxes, Pentstemons, and perhaps Delphiniums—and would certainly where a prize is offered for these in a separate class, but then I think it ought to be mentioned in the schedule. I have seen the same thing frequently done in the case of stove and greenhouse plants, from collections of which Fuchsias and other plants for which separate classes were provided were excluded. Where, however, they are admitted I am of opinion that only one bunch of any of them should be put up, and on this bunch it would not be necessary that they should all be of one variety; for that would entail the necessity of the exhibitor growing a large number of two or three varieties instead of a general collection. Moreover, the exhibit itself would be prettier by the number of varieties shown. I have personally a great objection to the Phlox as an exhibition flower; it very soon shows signs of flagging, and, if the day be hot, presents an unlovely appearance. My idea of a perfect collection of herbaceous plants would be that of one confined to species. However, I fear that this is not likely to find favour at present, and therefore I must be content with laying it down as a rule that where prizes are given for any flower in the schedule that flower should be excluded from the herbaceous stand, and that there should be only one bunch of such florists' flowers as are admissible.

With regard to Lilies, I think the case is entirely different. The different groups into which they are now divided present such totally different form and colouring that I do not think any limit should be put to them. Take, for example, *auratum*, *Harrisi*, *dalmaticum*, and any of the so-called Tiger Lilies; the *pardalinum* group, or the commoner forms of *tigrinum*. What can be more different? and how much they enhance the beauty of a stand. If I would exclude any—but this is simply a personal matter—it would be *auratum*, on account of its very heavy perfume. Where many of its grand flowers are shown the place becomes (to me) intolerable; but, of course, this would not entitle it to exclusion. I should not object to see in a stand of twenty-four varieties of herbaceous plants as many as half a dozen of Lilies, and then they should be as nearly distinct from one another as from any other flower in the collection.

Having thus indicated what I think ought to be and what ought not to be included in a stand, I now come to the very difficult question of judging them, and what is the determining point. Some say effect, and others the quality of the flowers. By quality I do not mean rarity, for this, I think, ought not to be taken into account; but by quality I mean the individual excellence of the flowers shown.

As to effect, there are two ways of viewing this; the production of a great mass of flower and its corresponding colour, or an arrangement which shows more the character of the plant without producing the same blaze of colour. This is one of those questions in which the idea in the mind of the judge must have a determining effect; it is so in other things. I have a neighbour who has been for many years an exhibitor of coloured Dorkings, and sometimes when I have asked him after a show how he got on, he has replied, "Oh! I knew I had no chance; old T— was judge, and he prefers so-and-so in the birds, and I do not go in for that." When one sees the gorgeous stands of bunches of herbaceous flowers shown by Mr. Burrell, there can be no question of their effect, even though some would say the bunches are like mops, and probably if the collection did not get first prize nine persons out of ten would say the judgment was bad; at the same time there is much more to be learned by the cultivator from a collection where the flowers are

set up with their natural habit of growth displayed. Let me, at the risk of bringing a house about my ears, give an instance which occurred during the past season at a show at X—. Two stands were set up by two well known amateurs, lovers of Roses and herbaceous plants. Long and anxious was the time spent in adjudication. They were each in their way of equal excellence, and it was a case in which I think equal first prizes might have been fairly awarded. They each had a rare plant, so that there was no advantage that way, if it is considered an advantage, although, as I have already said, I do not think it ought to be. One displayed a larger quantity of flowers in each bunch; the other showed more the habit of the plant, and was more elegant in its arrangement. I think anyone will see what a difficult task this was, and the diversity of opinion expressed by those who knew anything of the subject showed clearly that the difficulty did not exist only in the minds of the judges; the effect in both stands was excellent, but then it was a different kind of effect.

Frankly, then, I do not see how the variations in judging are to be avoided unless the schedule lays down very distinctly on what lines the judges are to decide. If they do not wish to encourage brilliant masses of colour, then it must be worded so as best to show the habit of the plants where practicable; and after all, perhaps it is one of those things which may be left to settle themselves. Managers of shows will keep their eyes open, and exhibitors will see what is required; and so, after a time, we may see stands of these delightful flowers which will satisfy the most exacting taste.—D., *Deal*.

PEACHES AND NECTARINES IN THE OPEN AIR.

THESE can be produced in great perfection in many places where proper care and attention are bestowed on the trees. In the far north and in some extremely cold districts they may not flourish, but in many cases where failures have taken place it is more the fault of the cultivator than of the soil and climate. I have seen gardens many miles to the south of where I write in which it was said Peaches would not grow on the open walls, only under glass, and the same remark has been heard many miles to the north. With an average amount of care I am of opinion that they can be grown, and that to a great state of excellence, in ordinary seasons.

On a recent visit to Wycombe Abbey I saw a grand crop of both Peaches and Nectarines on the walls. They were produced on both young and old trees. The secret of success seemed to be to keep the trees in a healthy state and never to allow the branches to become crowded. Where this is allowed to take place the shoots can never ripen thoroughly, hence weak blossom is the rule, and this is destroyed by the first frost in spring. Mr. Miles is so well known as a veteran grower both of fruits and vegetables that one expects to see everything well done, and the trees are living witnesses of good treatment. Many of them are getting old but still bearing excellent crops of fine fruit.

The system adopted is to keep on planting maiden trees year by year as space can be found, and by this means always having some well established trees at hand to replace any that show signs of decay. There can be no doubt that this is an excellent plan where space can be found on the walls, as the trees become acclimatised in a great measure, and they can be transplanted to any part of the garden required. An important feature in growing Peaches in the open air is to keep the roots as near the surface as possible, for when these get deep down into a cold subsoil the wood seldom ripens properly. I consider Peaches and Nectarines amongst the very best trees to transplant if done frequently. It is possible to transplant a large tree and secure a moderate crop of good fruit the same year.

All kinds of stone fruit prefer a firm soil, and unless this is given them failure is almost sure to follow. One-year-old maiden trees are the best to plant, as they can be trained into any desired shape according to circumstances. The object should be to secure as many young shoots as can be ripened; they must not be crowded. I would advise the very earliest varieties being planted, as well as some of the latest, so as to prolong the season. In the autumn as soon as the leaves have fallen the young shoots should all be loosened from the walls and only the old or main shoots left fastened up. This will, in a measure, prevent the trees from coming into bloom very early, as the cold winds will get behind the shoots and help to retard them. As a rule they should be protected from frost in spring, for no matter how much one tries to keep them back they will always be in flower before danger of frost is over.

The following varieties were all bearing good crops at Wycombe Abbey, and I may add that most of the varieties have not failed for years, although we are situated in an exposed part of the country.

PEACHES.—Alexandra, a large, handsome, first early variety; Waterloo, an American variety, bright red, of medium size, very early; Hale's Early, medium size, very early and handsome; Early Grosse Mignonne, very richly flavoured; Royal George, large and handsome when well grown, and one of the very best; Goshawk, an American Peach, and by many considered to be the best midseason variety grown; Crawford's Early, large and finely flavoured; Noblesse, large and richly flavoured, tree tender in some positions, but well worth growing; Bellegarde, large and good, one of the best; Dymond, tree hardy and very prolific, fruit large and highly flavoured; Sea Eagle, large, pale in colour, but of good flavour; Barrington, a strong grower, but the fruit is melting and excellent; Late Admirable, one of the best for late use; and Lady Palmerston, large and handsome, very late.

NECTARINES.—Lord Napier, without doubt the best early, it is large and handsome; Dryden, large, good grower and bearer; Elruge, medium size, one of the best; Violette Hâtive, large and highly flavoured; Stanwick Elruge, rich and good; Pineapple, handsome and finely flavoured; Victoria, very large, but should be planted on a warm sheltered wall; and Albert Victor, melting and good.

Both Peaches and Nectarines are named in the order in which they ripen. There are many other varieties that could be grown, but all those named can be depended upon to produce a good crop in ordinary seasons. To those who prefer Nectarines to Peaches, I can recommend Spencer as being one of the handsomest exhibited this season. Mr. Rivers speaks very highly of it, and describes it as one of the largest grown, and as being very rich and good.

It would be interesting if other growers would record their experience with outdoor trees, as it is by comparing notes that we gain knowledge which can be utilised at this season, when we should be preparing for giving any new or untried variety a chance by adding it to our selections.—J. SMITH, *Mentmore*.

NOTES ON HYACINTHS.

(Concluded from page 255.)

It will be necessary for them to remain in the plunging material about six weeks, but they should be carefully examined after they have been in a month, for they must not be allowed to draw while in this position. When once they have formed a good per-centage of roots they grow quickly, even rapidly, if the weather is genial. The ordinary methods of plunging amongst ashes, or covering them over, will not do when the object is to exhibit the plants. The position selected should be a north one, for it is better to retard at the commencement than near the show date. The crown of each bulb should be covered with a small pot, which will insure it against injury from any hard substance. The spaces between the pots can be filled in with coal ashes which have been passed through a fine sieve; in fact if cocoa-nut fibre refuse is not at hand they can be covered over with this material to the depth of 6 inches. If severe weather should intervene before the plants are removed from the plunging material they should be protected by spreading litter from the stable over the surface. There is no fear of injury by frost, but it might be impossible to examine them and remove them at the exact times required if frozen.

When removed from the plunging material they require the most careful treatment. They should be placed in a frame or structure from which frost can be excluded. The small pots should still remain on them, and a mat should be placed over the lights of the frame. In short, they should be most carefully and gradually exposed to light. Sudden exposure will ruin all chances of success. What growth they have made is in a highly blanched condition, and the object is to admit light so gradually that injury to the foliage or the spike cannot take place. When green they should have a light airy position near the glass at once. Do not place them on a shelf, it is too dry for them; they delight to stand on a cool moist base. To give them these conditions I would rather have them a small distance from the glass than close to it on a shelf. The object from this time is not to push them into growth, but to allow them to grow as naturally as possible. Artificial heat should not be used, except to exclude frost. Bear in mind that a close confined atmosphere, if only for a short time, is certain to increase the length of the foliage, and to some extent destroy its sturdiness, while it also increases the length of the flower spike from the top of the bulb to the base of the flowers. This tells against the plant on the day of exhibition. The chief aim of the cultivator must be to treat the plants as naturally as possible, shielding them only against the adverse circumstances that would tell against them in a state of nature. When the season is fairly advanced a cold frame is the proper place for them, and if they display the least signs of coming on too fast they should be removed to a frame with a

northern aspect. When well grown they need no staking except for removal to the exhibition, when a stake is necessary. A stake, however, should be used to prevent the spike falling from any cause and being broken.

The plants should be watered after they are removed from the plunging material, and from that time they should never be allowed to suffer by an insufficient supply. At first growth is slow, very little evaporation takes place, and water should be given with care. If they are over-watered the foliage is very liable to take the lead of the spike, which must be prevented, and which can only be accomplished by care and judgment. When rich soil is given stimulants in a liquid state should be supplied with care; the plants will not need much extra support. Clear soot water acts quickly in the later stages, and imparts a fine dark green hue to the foliage. Liquid made from cow manure, fresh, tied up in a bag, and placed in a tank of water, is also good when used clear. After they reach a certain stage feeding assists the plants in lengthening out their flower spike.

Dressing I need say little about. Those with large loose bells do not lend themselves to the dresser's skill readily, and can very rarely be improved much. The case is different with those that have their bells thickly set on the spike. They would often be too crowded, and fail to show their bells individually, unless one here and there were removed. Bells that have short stems, and which would destroy the symmetry of the bloom, are those that should be removed, they will make room for the others. The spike can be lengthened by slightly pressing down the lower bells and filling up the top; if this is well and carefully done the top of the spike can be made full and even, while the base can be rendered symmetrical. The varieties that tell best are not, as a rule, those of loose habit, but those that are full and by a little arrangement of the bells have full, large, shapely spikes with well developed bells. Nothing can be done at the foliage to improve the plant. If they are well grown there is nothing to be done, but if poorly grown, and any attempt is made to improve the foliage, they are only disfigured in the eyes of those who know what a well grown Hyacinth should be.

A plant with too little foliage is as bad, speaking from a judge's point of view, as a plant with too much—that is, with its foliage too long. The latter would, no doubt, take precedence, because it would possess the best spike and bells. Having plants with the foliage drawn may be due to two causes at least—first, hurrying the plants in their last stages, or growing them in too confined an atmosphere. If the plants are too early, and they have to be retarded, up goes the foliage and the stem of the spike. Unfortunately, also, the flowers lack that brightness of colour which young fresh flowers possess, or those that have been well grown and staged at the right age. The plant that is deficient in foliage according to its age very rarely has a first-class spike; if it has it is an accident, and would have been wonderfully good had all gone well. A plant deficient in foliage is also deficient in roots. If the spike is of fair size, which sometimes is the case, the flower lacks colour, substance, and size of bells.

A list of varieties will not be given, because all good catalogues contain the most suitable sorts distinguished by some mark or other. The amount to be expended on the bulbs must also very largely determine the selection to be made.—WM. BARDNEY.

THE NEW GERMAN CARNATIONS AND PICOTEES.

SINCE Mr. Benary of Erfurt introduced the famous yellow *Carnation Germania*, the finest of all the yellow selfs, much interest has been felt by many leading cultivators in the new varieties annually raised at Erfurt, and some very fine varieties have been introduced by Mr. Benary—notably, *Stadtrath Bail*, *Theodor*, *Esmarsh*, *Sarony Unger*, *Von Bennigsen*, *William Dreer*, *Madame Van Houtte*, *Van Dyck*, *Von Helmholtz*, *Schleiben*, and others. Many of them are novel and most pleasing in their shades of colour. The autumn of 1891 brought a batch of other new sorts from Mr. Benary which have been well tested this season at the *Sparkhill Nurseries*, *Birmingham*, by Mr. Herbert, and from amongst them the following will be welcomed by growers as acquisitions—viz., *Johann Huss*, lemon ground flushed with delicate pale rosy pink, a very lovely and distinct variety; *Heinrich Engel*, maroon and scarlet flaked, the latter colour very bright, a large, distinct, and very fine flower; *Brockhaus*, orange-salmon ground colour, flaked and barred with heliotrope, fine form, a well-built flower, distinct and extra fine; *Justus Meyer*, a very distinct flower of an almost indescribable colour, a rich brown lilac tint with a bright satiny surface, and flaked with scarlet, and here and there a crimson bar; *Mommson*, orange ground flaked with crimson lake, with a distinct broad margin of bright heliotrope, a beautiful

and distinct variety; *Klopstock*, a deep rosy carmine self, a bright shade of colour, and of fine form; *Gilbert*, a grand flower with fine broad petal and of full size, rich bright rosy carmine; *F. A. Haage*, orange ground colour flaked with carmine and deep heliotrope, fine and quite distinct; *Consistorialrath Reush*, a very distinct flower with a large extent of canary ground colour, flaked with a crushed strawberry shade of colour, fine petal and form, and distinct; *Celsius*, yellowish buff distinctly flaked with scarlet, a very distinct and fine *Carnation*; *Emilia Galotti*, pale lemon suffused with salmon, good form and distinct; *John Benary*, shaded rosy pink with orange-scarlet and rosy-purple bars, very distinct and fine; *Pastor Schultze*, primrose yellow ground with flakes and bars of bright violet purple, a distinct and fine variety; *Cordula*, a blue tinted slate ground flaked with bright scarlet, a very distinct and fine variety; and *Schlosser*, sent out in 1890, creamy yellow ground flaked and broadly bordered with heliotrope and bright rosy crimson, broad petal, of fine form, and distinct.

Several other new varieties were introduced in the autumn of 1891 by Mr. Benary, some of which are very curious in their markings and colours, but will not be regarded as acquisitions for exhibition purposes. If new varieties are to become popular amongst the growers for exhibition the flowers must be of very fine form, and possess other good properties. Others of Mr. Benary's will have another season's trial. English cultivators are greatly indebted to him for introducing some extremely fine varieties, with new shades of colour. Almost all his new varieties have good constitutions, and are strong growers, producing plenty of "grass" or offshoots. Mr. Benary was present at the last August Exhibition of the *Midland Counties Carnation and Picotee Society* at the *Edgbaston Botanic Gardens*, *Birmingham*, and had an opportunity of seeing how well his new varieties have been grown and exhibited, by the midland growers especially.

Another florist in the neighbourhood of Erfurt also introduced during last autumn some new varieties of German origin, and has evidently a good strain, rivalling in some respects Mr. Benary's. Amongst Mr. Ferdinand Jühlke's new varieties the following are acquisitions—viz., *Frerna Beweoldt*, bright yellow ground, with flakes and bars of bright crimson maroon, and quite distinct; *Don Juan*, creamy yellow, flaked and barred with bright plum and crimson; *Mazeppa*, orange ground colour suffused with bright carmine and flaked with maroon, a fine and very distinct flower; *Beethoven*, orange ground, heavily flaked, and marked with deep heliotrope; and *Golfina Hoffmann*, white ground, heavily barred with bright rose, tinted mauve, and edged with a deeper shade of colour, a handsome variety of dwarf compact habit.

All the varieties enumerated in these notes are classed as *fancies* or *selfs*, *Carnations* and *Picotees*. They are becoming very popular for decorative work, either in pots or in borders, and they last well in a cut state in rooms. For conservatory and indoor decoration plants can be easily grown in 5 to 6-inch pots, and they are beautiful when so grown.—W. D.

POTTING MARGUERITES.

THOSE whose stock of these useful plants is limited should make a point of potting as soon as possible plants which are now growing in mixed borders or in the flower garden. No doubt many will be reluctant to spoil, to a certain extent, their bedding arrangements; but it is not safe to defer this work any longer if the plants are wanted to supply cut flowers during the winter, for a few degrees of frost seriously cripple the young shoots, on the points of which flower buds have already formed.

Marguerites which have been used as dot plants are the best for the purpose, because on account of their being thinly disposed the growth made is sturdy and floriferous. In many instances such plants can be lifted without spoiling the appearance of the beds; in our own case it is so. We have them as dot plants along the centre of large beds, in which Ivy-leaved *Pelargoniums* form the groundwork. A few pegs will be removed from these, and the shoots laid aside. It will then be a simple matter to cut round the *Marguerites* with a spade, and lift them with good balls of earth. The less these balls are disturbed the slighter will be the check upon the plants, but it is sometimes desirable to place large plants in comparatively small pots; a considerable amount of the soil must then be removed and the roots cut clean with a knife before the plants are potted.

This treatment will cause them to suffer severely for a time, but it is really surprising how quickly these accommodating plants recover from the check. A few weeks ago I had occasion to pot a few which were about 2 feet in diameter, the roots of which had run rather wide, and only an imperfect ball could therefore be obtained. These were potted into 7 and 8-inch pots, placed behind a north

wall, thoroughly watered, and kept syringed four times a day. Notwithstanding these attentions the plants flagged so badly that I reduced the growth on some of them by about one-half. I soon regretted having done so, however, for those not reduced had thoroughly recovered in a fortnight from the time of lifting without—as far as I can see—the loss of one flower bud, and only a very few leaves. These plants are now flowering freely, and promise to continue doing so for a long time to come. I mention this to prevent others from being discouraged should their plants flag badly after being lifted. When this happens some are inclined to believe the thing cannot be done satisfactorily, and therefore discontinue the necessary attention, when, of course, unsatisfactory results follow.

Plants potted up now should be placed where they are safe from frost; deep cold pits, where they can be kept close, as well as syringed and shaded, are the best positions for them. Vineries or Peach houses, where there is plenty of foliage overhead, and no fruit hanging to prevent syringing being done, are fairly good positions, or they may be placed in a shady place in the open air for a couple of weeks yet if no very sharp frosts occur. While in the latter position it will be necessary to devise some means of covering with mats or canvas whenever frosts threaten, at other times the cool night air and heavy dew will help them wonderfully towards recovery.—H. DUNKIN.

WHEN ANNUALS ARE NOT ANNUALS.

THE following very interesting extract is from a number of contributions to the life histories of plants, by Mr. Thomas Meehan, at the Academy of Natural Sciences of Philadelphia. Perhaps some readers will note with surprise the American savant's conclusions that "any annual may be made perennial:"—

Prof. Theo. Holm, of the Smithsonian Institution, is the author of a suggestive paper on the vitality of some annual plants. He notes a number of species generally recognised as annual which frequently furnish biennial or perennial individuals. Such observations are especially useful, for it is deviation from general rule that furnishes us with keys to unlock the great treasure-box of Nature's secrets. If we can show that annuals are not always annuals, but sometimes become perennials, we have the opportunity to watch the process, and learn as the work goes on.

Horticulturists must have long known, without giving the matter serious thought, that annuals become perennials under some circumstances. Petunias, Gaillardias, and indeed I can think of no annual plant of any kind whatever, that the horticulturist cares to preserve, that he cannot preserve from cuttings when he so desires. Even in the case of those annuals which throw up only a single flower scape, he plucks off the flower head before the flower buds expand, cuts up this flower stem into sections, and raises plants which will live continuously for many years, if annually treated in the same way. Annuals or biennials will live for many years if the flower buds are plucked out as soon as they appear. The author of this paper has seen Mignonette six years old that has been treated in this manner. Annual parts of perennial plants also live over when propagated in the same way. Perennial Phlox, Hollyhock, and similar plants are raised from sections of the flower stems which have had their flower heads taken out a few weeks before they were cut into the segments desired.

It is worthy of remark that few plants except those which we distinctly recognise as ligneous, have perennial parts. The Potato lives only through the tubers it makes annually, and even the Strawberry plant will be found to be dead below the addition of the past year. Gladioli, Lilies, many terrestrial Orchids, and numerous other plants, only live over through the additions of the preceding year. The older portions die after new portions have been formed. In brief, the power to produce offshoots or stolons is really the only difference between the annual or perennial herbaceous plant.

It may now be further noted that, morphologically, there is no difference between a stolon and a flower scape, a rhizome or a permanent flower stem. The Strawberry is one of the best illustrations of this. The "Bush Alpine" never makes a "runner"—all that would be stolons becoming erect flower scapes. The transitions between flower scapes and stolons may be seen at any time by the careful observer. But the flower scape is an annual, while the stolons remain over until another season.

We may now consider the causes inducing the annual or the more enduring conditions. It is now well understood that though the reproductive condition of a plant is a natural outgrowth of the vegetative, there is a certain antagonism between them. The husbandman must root-prune, or take off a ring of bark, or practise some such severe measure, before an extra vigorous tree can be

made productive. On the other hand even sound trees have been led to death's door by over-bearing. Annuals die from no other cause than by the heavy draft on vital power through bearing seed so early and profusely, with nothing but a single rootstock to provide nutrition for the whole.

Professor Holm, though he is not clear whether it is climate, soil, cultivation, or other cause which leads the annual occasionally into the perennial class, quotes Lange as showing that *Carex cyperoides*, under normal conditions truly annual, is "able to vegetate several years when it happens to live without flowering." Several years ago I had a number of plants of the Caraway, *Carum Carui*, transplanted after they had commenced to push up flower stalks. As the flower stalks withered, they were plucked out to the base. All the plants became bushy perennials! Profiting by the hint I have some plants, with the stems annually plucked out, that are now four years old.

Going back to the Strawberry, why does the scape die the same season, and the stolons endure? Is it not that the stolons, sending out roots at the end which form leaves instead of flowers, are under more favourable conditions of nutrition? The scape is drawing heavily on vitality which the unfavourable conditions of nutrition do little to sustain.

I have little doubt but that any annual may be made perennial by persistently destroying the flower buds as they appear. When we see in a state of nature, some few plants survive while numbers perish the season of their birth we may reasonably look for some circumstances which in these plants led them to bear seeds less profusely than others, or to some other condition which aided the vegetative in its struggle with the reproductive forces.

CUCUMBERS AT FARNHAM, SURREY.

PHOTOGRAPHIC pictures of crops of hanging Cucumbers sometimes shown have elicited much credulous surprise, because of the astounding abundance of the crop. Of course these pictures do not represent crops in course of cutting for consumption, because in such cases the fruits are cut as soon as ready. Plenty of counterparts of these Cucumber pictures may, however, be found in houses where plants are grown to produce seed, and especially was this the case at Mr. Mortimer's Swiss Nursery, Farnham, recently, where many large, long houses are devoted to Cucumber production for seed purposes. It is not at all improbable that he has this season fully 5000 fruits to clear out, and will thus harvest considerably over half a million seeds. The varieties grown almost exclusively, and each one in separate houses, are Telegraph, Improved Telegraph, Tender and True, Lockie's Perfection, Epicurean, Matchless, and Success. The latter variety, which is one of the largest and certainly handsomest of Cucumbers, was certificated during the present year by the Fruit Committee, and it will be very difficult to excel it in beauty as well as in length and general appearance. It may be of some interest to state that the immediate parents of this variety were Express and Prizewinner, the latter a handsome variety but not sufficiently free. Its parentage is not known. Express is the product of Tender and True × Purley Park Hero, which is one of Mr. Mortimer's earliest seedlings. Success runs about 24 to 30 inches in length, is slightly spiny, very even throughout, has hardly any handle, and is particularly handsome and productive. Last year the Fruit Committee certificated Matchless, which, whilst also very handsome and green in colour, was found to be rather too short for exhibition purposes. When the other day at Reading a brace of Success were shown no other fruits could at all compare with them in form or beauty. Matchless came from Express also × Lockie's Perfection. Purley Park Hero came from Improved Telegraph × Model. It would be very interesting were the various pedigrees of all fruits and vegetables carefully recorded.

The houses in which the Cucumbers are grown at Farnham are both lean-to and span. The borders for soil are very shallow, not more than 5 to 6 inches deep and 18 inches wide. The soil is the best stiff turfy loam the district will afford, and to it is added a moderate portion of horse droppings; a couple of dressings of Thomson's manure (one of the best for Cucumbers) are given during the season. Prior to the planting of the Cucumbers in some of the houses a crop of early Tomatoes is secured, and as soon as the Cucumbers are off the houses are filled with plants for the winter, especially Chrysanthemums. Even Tomatoes do not get surplus soil, for in one house of Perfection—a large span, 60 feet by 10 feet—the plants have only a shallow 18-inch wide border, and the plants are 16 inches apart. Coleus for seed are very largely grown; the varieties are of all descriptions, whilst the major portion are seedlings. The long spikes of tiny blue flowers bear a very pleasing appearance. Seed is sown the third week in March, the plants flowering in large 32's; of course, for the production of flower the plants are not stopped. Other houses are devoted to the growing for seed of beautiful Celosias in various colours, also of a very fine dwarf crimson race of Cockscombs. A very large stock of small sturdy Fuchsias in great variety is kept, and from these are propagated in the spring tens of thousands of cuttings, which are sent out to the trade in a rooted state. Somewhat stunted plants in 32's and 48's seem to give the stoutest and most liberal supply of cuttings when wanted in the spring.—A. D.

EVENTS OF THE WEEK.—The usual Committee meetings of the Royal Horticultural Society will be held at the Drill Hall on Tuesday, October 4th, when prizes will be given for hardy herbaceous perennials, and a paper on Michaelmas Daisies will be read by Mr. D. Dewar. On the 5th, 6th, and 7th, a great Show of Fruit and Potatoes will be held at the International Horticultural Exhibition, Earl's Court. On the evening of the 5th the annual dinner of the United Horticultural Benefit and Provident Society will take place at the Cannon Street Hotel at 6 P.M., J. Fraser, Esq., of Lea Bridge, presiding. On Friday, September 30th, there will be a great sale of Cattleya Rex and other Orchids at Messrs. Protheroe & Morris' rooms by order of Messrs. Linden. For particulars of other sales see advertisements.

— **THE WEATHER IN LONDON.**—Although the weather has been less settled during the past than it was during the preceding week there has been no appreciable amount of rain, only a few light showers having occurred to break the generally fine and warm weather. On Tuesday evening the cyclonic disturbance which reached the north-west coast appeared to have touched London, as a somewhat high wind prevailed and a little rain fell, but at the time of going to press the weather is calm, clear, and promises to be fine, while the barometer is rising.

— **ROYAL HORTICULTURAL SOCIETY.**—At the next meeting of the Royal Horticultural Society, which will take place in the Drill Hall, James Street, Westminster, on October 4th, prizes will be offered to amateurs for hardy herbaceous perennials, and a paper on Michaelmas Daisies will be read by Mr. D. Dewar, which should be of much interest.

— **NEW WORK BY MR. WILLIAM PAUL.**—We have received a copy of Mr. William Paul's "Contributions to Horticultural Literature," being a selection of articles written for gardening periodicals and papers read before various societies from 1843 to 1892. An admirable portrait of the author adorns the work. We shall take another opportunity of referring to this instructive volume.

— **CARNATIONS AS ANNUALS.**—I herewith send you a few flowers of Marguerite Carnations, from seeds sown on February 11th this year. The plants have been blooming for about ten days. They were established in 5-inch pots by the end of May, at which date they were plunged in the open, and placed in a cool Peach house as they came into bloom. No doubt better blooms could be produced in the same time by giving larger pots.—R. I. [Bright, varied, and sweet. With the improvement in the flowers that is likely to be effected, we shall have a very valuable class.]

— **A WELSH FUNERAL.**—Mr. William Wright, gardener and bailiff to G. T. Clark, Esq., Talygarn, South Wales, who died on the 21st inst., was interred on Saturday last. It appears to be a custom in Wales to show respect to deceased friends by assisting in carrying the bier. About sixty persons, the majority being workmen on the Talygarn estate, preceded the coffin, four of these taking the bier in turn for short distances, till most or all shared in the mournful duty. The changes were done with such order and regularity that there was scarcely a pause in the procession. There was also a large number of followers. The coffin was laden with beautiful wreaths from Mr. and Mrs. Godfrey Clark, Miss Wyndham Lewis, the officers of the United Horticultural Benefit and Provident Society as a token of respect towards a deceased brother and ex-member of Committee; Mr. A. Pettigrew, Cardiff Castle Gardens; Mr. G. W. Cummins, Hackbridge Gardens; the family of the deceased, and from his brother, Mr. J. Wright of the *Journal of Horticulture*. The family of the late C. M. Major, Esq., Cromwell House, Croydon, to whom the deceased was formerly gardener, also sent flowers. Mr. William Wright (who had only had twelve birthdays, having been born on the 29th of February) was a highly competent gardener, also a good farmer, and he had a wide and intimate knowledge of estate work generally. His services were much appreciated by his employers, whose kindness during a protracted illness was unbounded. The deceased had been an unusually strong and healthy man, described by Mr. Pettigrew as a "Hercules." Bright's disease, which followed a severe attack of the influenza last autumn, was the cause of death.

— **DEATH OF MR. LUPTON OF WAKEFIELD.**—Horticulturists in Yorkshire, and particularly those interested in the Wakefield Paxton Society, will hear with regret of the death of Mr. Lupton, host of the Saw Hotel in the town named. He took a great interest in gardening, and was a sincere friend to the Society.

— **FINE MUSCAT HAMBURGH GRAPES.**—When at the Kingswood Show I saw the three best bunches of Muscat Hamburg that I have ever seen. They weighed collectively 9½ lbs., were very regular, and as black as Sloes. The owner, Dr. H. Grace (a member of the great cricketing family), was very proud of them.—W. I.

— **MAGGOTS IN PEACH TREES.**—Can anything be suggested that will prevent maggots boring into the stems of Peach trees, causing them to gum badly? They attack one after the other, and I very much fear they will go all through the house. If any of your readers have had anything of the kind to deal with they may be kind enough to help me.—J. B.

— **ASTER NOVI-BELGII LADY TREVELYAN.**—For free flowering it would be very difficult to find any variety of the Michaelmas Daisy family that excels the one here named. It is a somewhat tall grower and of ample proportions, covering itself with a dense cloud of small white flowers. It forms one of a large collection in the nursery of Messrs. Laing & Sons at Forest Hill.

— **FRUIT EVAPORATION.**—Visitors to Earl's Court on the occasion of the great fruit and vegetable Show, which opens next Wednesday, may be interested to hear that demonstrations of fruit evaporating will be given in the gardens of the Royal Horticultural Society at Chiswick on October 5th and 6th by Messrs. Ph. Mayfarth & Co. The process is very interesting, and as the gardens, which possess many other features of interest, are easily and quickly reached from Earl's Court, some may like to "do" both functions.

— **IXIAS.**—Among early summer-flowering bulbous plants *Ixias* are deserving of a prominent position. When cultivated in pots they are very ornamental and attractive for greenhouse and conservatory decoration. They bloom most profusely, are invaluable as cut flowers, and possess a variety of colour rarely seen in any other class of bulbous flowering plants. They require similar treatment to Freesias, with the exception that they do not require much heat—in fact, they succeed best without any. The best plan is to keep them in a light airy position throughout, taking care to avoid draughts.—G. P.

— **THE BLUE PIMPERNEL.**—When I saw this very charming old garden flower, called where growing at the London Road Nursery, Reading, *Anagallis grandiflora* Phillipsi, the other day, I could not but feel surprise that so lovely a blue flower was not employed by those who have to furnish bedding displays in the summer. Not perhaps of itself would it do, but intermixed, as an edging for instance, with *Mesembryanthemum cordifolium variegatum* how beautiful it would be. Blue flowered plants are somewhat scarce in gardens, especially of that rich deep blue which characterises the flowers of this Pimpernel. The large red variety is also pretty, but the blue naturally seemed to be the most striking. The variety would also make an effective ground-work for rich coloured Begonias. It is a natural ground creeper, and requires very little attention. It can be propagated by seed, for it comes very true, and also by cuttings kept through the winter.—A. D.

— **FREESIAS.**—Freesias are among the most beautiful and handsome of all the Cape flowering bulbous plants, possessing grace of form and being admirably adapted for greenhouse culture in pots. The plants attain to a height of from 9 to 12 inches, according to the variety, *F. refracta alba* being rather taller than *Leichtlini*. The flowers are very attractive and deliciously fragrant, one pot of five or six bulbs being sufficient to perfume a whole house, and when cut and placed in water they retain their perfume for a long time. If the bulbs are not already potted no time should be lost in performing that operation. A compost of good fibry loam, leaf soil, and dried cow manure, with a sprinkling of silver sand, will suit them admirably. Use 5 or 6-inch pots, placing six or eight bulbs in a pot. The different sizes should be placed together, in order to have plants uniform in strength when flowering. Water sparingly until growth commences. A frame where frost can be excluded will be best till the young shoots appear, when they should be removed to a greenhouse, as plenty of air and a light position are most conducive to a dwarf sturdy habit. When the flower spikes appear the plants should be removed to where more heat can be applied, as a much finer display can be obtained than is possible if grown in a cooler temperature.—G. P.

— **EUCOMIS PUNCTATA.**—The usefulness of *Eucomis punctata* for greenhouse decoration is well exemplified at Forest Hill just now, where Messrs. Laing & Sons have a number of well grown plants interspersed with other occupants of a flowering house. They give a very distinct and handsome effect, the tall spikes rising well above the majority of their associates. *E. Regia* is also grown and is a noteworthy object.

— **PRESTON AND FULWOOD HORTICULTURAL SOCIETY.**—The forty-eighth monthly meeting of the members and subscribers will be held in the large room of the Legs of Man Hotel on Saturday evening, October 1st, 1892, when Mr. W. P. Roberts of The Gardens, Cuerden Hall, will read a paper on "the Cultivation of the Fuchsia." The chair will be taken by the President (J. Humber, Esq.) at 7.30. Prizes are offered by Alderman Galloway, J.P., for six dishes of outdoor fruit, distinct; and by the Secretary for two bunches of Grapes, any variety.

— **NEWCASTLE AND DISTRICT MUTUAL IMPROVEMENT SOCIETY.**—We are glad to record satisfactory progress on the part of this young body of horticulturists, and to note, in the first annual report just issued, that the financial statement shows a substantial balance on the right side. The membership is rapidly approaching 100. Many excellent papers were read during the Society's first season. Its meetings are held in the hall of the Literary and Scientific Institute, Westgate Road, on the second Wednesday of each month, at 7.30 P.M.

— **ASTER AMELLUS BESSARABICUS.**—This variety is now making a brilliant display in the herbaceous border, reminding one of the near approach of autumn. It is undoubtedly the finest of all the Michaelmas Daisies. The height which it attains to renders it suitable for so many purposes that the wonder is it is not more often seen in private gardens. As an edging to a mass of *Chrysanthemum Madame C. Desgranges* it is very suitable, as both plants flower at the same time. In the herbaceous border, now that the August dazzle is past, this *Aster* supplies a want. Its deep purple flower heads are very showy, and its habit is compact, growing not more than 2 feet 6 inches high at the most. Like the bulk of the family propagation is a simple matter—by dividing a good sized root numbers of plants can be obtained.—E. M.

— **TRITOMA GLAUDESCENS.**—This is decidedly the best of the Flame Flowers, as it produces its torch-like blossoms much more freely than any other, and much earlier than the type *uvaria*. While the latter shows no signs of flowering the former is at this date (September 8th) in full blossom. The colour of the flower is inclined to golden orange on the lower part, not being so red as *uvaria*. *Tritomas* are not suitable plants for the ordinary herbaceous border; they need all round space to show off to the greatest advantage. We have them growing at the present time in just the place which suits them—on the grass in a part of the garden which is not mown with the machine but cut over occasionally with the scythe, the plot being mainly occupied with bulbs. In this particular spot, where the foliage has free space for development, the *Tritomas* grow well and look their best. Another place is by the water side. In an artificially built pocket 9 inches square, close to the water, one plant has twenty fully developed spikes, and as the background is mainly composed of *Rhododendrons* the effect is enhanced considerably.—E. M.

— **ASTERS.**—This year *Asters* have been finer than I have hitherto seen them, although the cultural treatment was the same as that bestowed upon them before, so that the marked improvement in the size, form, and colour of our *Asters* this year must be attributed to the particular strain (Webb's) grown this season for the first time, and not to any special treatment. The flowers of the several varieties contained in the "Wordsley collection" are unusually large, deep, full, and of fine and well-defined colours, ranging from pure white to rich crimson. They have been and are still greatly admired by all visitors to these gardens. The seed was sown in a cold frame in light fine soil placed within a few inches of the glass and covered lightly with some mould of the same description, which was then patted down with the back of a spade to compress seed and soil. Afterwards they were watered through a fine rose and the frame kept close and shaded until the seedlings came up, when a little fresh air was admitted to them, the quantity being gradually increased until the seedlings were transferred to the borders where they are flowering. The plants were 1 foot apart, and the dwarf growing ones were placed nearest the walls, a showery day being chosen for the operation, and the plants afterwards watered (in the absence of rain) every afternoon until the roots had taken well to the soil, when water was afforded less frequently. The only other attention they got or required was to keep them free from weeds and give them needful support in the way of sticks and ties.—H. W. WARD, *Longford Castle*.

— **THE MIGRATION OF APHIDES.**—The usual autumnal migration of aphides has been taking place across this district during the last few days, being somewhat later than usual. According to the popular belief it has happened in that cloudy, comparatively calm weather when people say there is a "blight." The motion of the majority of them seemed to be in a westerly direction, and they are probably journeying from the districts where many Hop grounds are situate to deposit next season's eggs on fruit trees and shrubs. It appears to be the general opinion about here that a hives of all kinds have been less in number than the average during this season. The fact is notable, because experience rather tends to indicate that a dry spring, such as we had, is favourable for their increase, and therefore an opposite result might have been expected.—J. R. S. C., *Gravesend*.

— **CHARLES' ECONOMIC PEST SYRINGE.**—A useful sprayer has been invented and patented by Mr. W. F. Charles of Loughborough. It consists of a can holding about a quart fitted with a brass screw cap, an air chamber having a network covering, a connection with an india-rubber ball, and a long brass tube fitted with slit and rose nozzles. The can is charged by unscrewing the cap, and on the latter being replaced and the air-ball squeezed until the net-protected chamber is distended, a thin stream or spray is given off according as the slit or rose-nozzle is used. The spray is carried to a distance of several feet, and falls in a dew-like state, while owing to the nozzles being adjustable, it can be directed either on the lower or upper side of the foliage. It affords a ready means of distributing a liquid insecticide on plants in greenhouses or windows, and amateurs in particular would find it very useful; moreover it is cheap. Messrs. Messenger & Co. of Loughborough, the well-known hot-water engineers, are introducing it.

— **NORTH OF SCOTLAND HORTICULTURAL ASSOCIATION.**—The annual meeting of this Association was held on September 21st, Mr. C. S. France, President, in the chair. The Secretary's and Treasurer's reports were read and adopted. From the accounts it appeared that there was a balance to the credit of the Society of £17 16s 10½d. The following office-bearers were then appointed:—President, Mr. C. S. France; Vice-President, Mr. G. Ross, Cranford; joint Secretaries, Mr. William Reid and Mr. J. Minty; Treasurer, Mr. Wyllie. The name of the Association was altered to the "North of Scotland Horticultural and Arboricultural Association." To Rule 3 the following addendum was made:—"Amongst means for extending the objects of the Society we are to grant awards for essays on and for collections of native herbaria and woods." Rule 5 was altered to admit apprentices at a subscription of 1s. per annum. Three silver medals were offered as awards for the subjects mentioned above—a maximum sum of £3 3s. being voted for the purpose. The usual votes of thanks concluded the meeting.

— **GIANT ONIONS.**—The report of the Banbury Onion Show rather leads to the inference that the chief object in raising new sorts of Onions is to get the biggest imaginable. Why should we set up a standard of that kind for Onions? It is not tolerated in any other vegetable. What, for instance, would be said of giving prizes to Potatoes or Turnips that weighed over 2 lbs. each? What earthly benefit to gardening is going to result from that sort of thing? I am very certain that no gardener would care to have for his main crop of Onions bulbs weighing 2 lbs., and it is also morally certain that any good average crop of 6 oz. to 8 oz. bulbs will give greater weight per rod of ground than the heaviest exhibition bulbs ever seen. All who are familiar with the method of culture adapted to produce these enormous bulbs know that each bulb occupies on the ground fully four to six times the area allotted to ordinary main crop Onions, also that they get fully double the amount of manure, feeding, and attention that ordinary crops receive. Further, when got they seldom keep into the winter, and finally they never would be grown as they are without the prospect of winning prizes. Moreover, the method of culture adopted, by generating a corpulent and weakened constitution, deteriorates the seed stocks of these big varieties, which for that purpose should be grown as ordinary crops for common use. Just recently I saw growing stocks under what may be called good ordinary culture, that is, had ample room and no special feeding, the Sutton's Globe and Sutton's Al, the former one of the most perfect globe or egg-shaped forms I have seen, as firm as bullets, and with skins as sleek and glossy as could well be conceived. These bulbs ranged from 7 to 9 ozs. each, and would keep well till next May. The other is a flatter Onion, but with a deep round base, and is also a fine stock, giving very even, clean, hard bulbs of good size. These stocks were just the kind that gardeners or growers for market would delight to possess. I should like to be taught the domestic value of Giant Onions.—A. D.

— BROCCOLI MICHAELMAS WHITE.—The fact of the bulk of our stock of this Broccoli turning in now proves how much this vegetable, like many others, is influenced by the weather. The great heat experienced during June and July brought the plants on fast. It is necessary in our soil to plant early to grow the plants into a good size before autumn. So good and close are the heads that it would be difficult to distinguish them from Veitch's Autumn Giant Cauliflower, and they have proved very useful in place of the last named. One head measured was 22 inches in diameter, which is exceedingly large even for a Broccoli, and this was produced on land which has been devoted continually to the Brassica tribe for the last twelve years, in spite of the assertion of some that this crop will not succeed even two years in succession on the same ground.—E. M.

— EDUCATION IN GARDENING AT EDINBURGH.—A bold and liberal scheme has been matured by arrangement between the Commissioners of Her Majesty's Works and the Board of Agriculture, whereby working foresters and gardeners may secure at the Royal Botanic Garden, Edinburgh, on very easy conditions, a thorough education in the principles of their arts and in the sciences on which they depend. The curriculum, which will extend over two and a half years, will be free of charge to those who are admitted, and the Council even propose to find employment at a moderate rate of remuneration in and about Edinburgh, and to some extent in the Botanic Garden itself, for young men from a distance, with a view to enable them to support themselves during the period of study. It is also suggested that the County Councils and other bodies having control of the administration of funds which could be allocated to such a purpose might, in different localities, see their way to making small grants to aid men desirous of working through the curriculum, and that many individual proprietors would be glad to give some additional pecuniary help to young men from their neighbourhood for the same purpose. Details of the scheme, which will come into practical operation next month, may be obtained by application to Mr. I. B. Balfour, keeper of the garden.

— STRAWBERRIES AND LIMESTONE SOIL FORMATION, CLONMEL.—I have been wondering why in some Strawberry experiments in my garden with numerous varieties some of them did no good whatever. At first I thought it might be position or relative richness of the soil, but after three years' trial I have come to the conclusion that soil formation plays a decided part in the success or failure of particular varieties. My soil is of limestone formation, partly made or carted in, and with a considerable share of limestone rubbish and sand mixed with the old original to our garden soil of ages. British Queen and Sir Joseph Paxton do no good whatever for me I am sorry to say. Dr. Hogg and Eleanor give famous crops of foliage—that is all. Vicomtesse Héricart de Thury and La Grosse Sucrée, poor results and little foliage. Of the newer introductions Noble is one of the first and heaviest croppers, and by no means deficient in quality, in a good sunny season. Scarlet Queen comes first of all my varieties for quality and earliness, but was rather small last season. Competitor is far and away the heaviest cropper, with it Auguste Nicaise (very liable to red spider) and Cardinal following close. I understand Mr. Laxton in his famous Strawberry nurseries at Bedford has somewhat similar results.—W. J. MURPHY.

— SENDING ROSES BY PARCEL POST.—I have just received a post-card from a friend at Bournemouth, about 150 miles away, to the following effect:—"Thanks for the lovely Roses. They are very much admired. Mr. O. thinks them splendid; they arrived so fresh, and looked as if they had just been gathered." Having received many similar testimonies from friends at long distances, perhaps a hint as to packing may be of use to some readers who may not have been so fortunate. In dry hot weather it is necessary to cut the blooms in the morning, with the dew on if possible, in order that they may retain their freshness and colour. They are then placed in water, with the stems several inches deep, removed to a cellar, and packed as soon as convenient. Small boxes of convenient sizes may be had from grocers or confectioners at a trifling cost, averaging 1d. each. I choose a box as near as I can guess suitable for the blooms at command—say, two or three dozen. The blooms preferred are those from buds commencing to open up to half expanded. These lie close, and may be disposed compactly without damage. The box is first rinsed with water, the wood absorbing a little without being made too wet for the post, and a lining of paper is used to save chafing of the petals against the rough wood inside. The stoutest and firmest varieties are chosen to lie against the paper. The blooms are laid carefully to fit firmly, but without crushing. They are laid end to end, with the stems in the middle of the box. When sufficiently filled a little finely cut young grass, which should not be

wet, is placed in hollow places among the blooms to prevent chafing, and to impart moisture in transit. A piece of paper is placed over the blooms, and on the top across the stems a roll of crumpled paper, or what is better in some cases, a quantity of Lettuce leaves. The box should be filled so that the lid requires a little pressure to hold all firmly to prevent any friction. I object to moss for packing on account of the scent.—J. HAM, *Astwood Bank*.

— PRICES OF OUTDOOR TOMATOES.—"We are getting 4s., 3s., and 2s. respectively per 12 lbs. for best seconds and thirds of outdoor Tomatoes," said a grower who sends many tons into Covent Garden Market during the season. The figures are far from being high, but they seem to be fairly remunerative. Outdoor culture is not a costly process. The first thing is to have good early free-fruited strains. Of these Earliest of All and Magnum Bonum, so far as I have seen, seem to be the very best, and both set and fruit wonderfully outdoors. Some of the choicer or handsome fruited, whilst doing well under glass, are of little value outdoors; and the grower who puts out thousands of plants soon finds out which sort suits his purpose. Then early strong plants fully 10 inches high should be ready to go out early in June. These should have ample room, and each one a stout stake some 3 feet out of the ground. Plenty of hard pinching and a little tying constitute the chief requirements of Tomato plants.—D.

— HEDYCHUM CORONARIUM.—The first of the genus introduced in 1791 from the East Indies, and designated the Indian Garland Flower, this Hedychium is worthy of culture by those possessing a good roomy intermediate house or stove. Our plants grown in the former house are just opening their charmingly scented snow white flowers, which show to great advantage, carried as they are on stems 4 feet high and clothed with pale green leaves, which show the white flowers to perfection. The individual flowers are very beautiful, and closely resemble many of the Orchids, in fact they are more pleasing than some of these. As regards their culture it is simple enough. When the flower spikes die down reduce the quantity of water, finally giving none at all. They may then be stored away during the winter in any out-of-way place not too cold. In February or March the rhizomes may be divided, using a good strong loamy soil, allowing plenty of room in the pots, as all the Hedychiums are strong rooters. Place the pots in a warm house, merely syringing well about them until growth commences, when the water may be increased, and as the strong, stout growths begin to push well up the application of weak supplies of weak liquid manure will be found of immense benefit. The plant rapidly increases, and it is for the cultivator to determine as to what sizes he will allow them to grow, and so use the roots to his own satisfaction. Insects do not trouble the Hedychiums very much; perhaps thrips may occasionally infest them, but they may soon be removed by sponging.—R. P. R.

— THE ROYAL BOTANIC GARDEN, CALCUTTA.—In the report of the Royal Botanic Garden, Calcutta, for the year 1891-92, it is shown that the year was one of great activity as regards outdoor operations. The abnormally dry season proved very trying to many exotics, and, though for a time all other work was suspended and the whole garden staff was employed only in watering plants, many casualties occurred, especially among the finer and rarer plants. The attention of the staff was as usual largely directed to the cultivation and distribution of plants of economic interest. The chief event of the year under this head was the introduction of the Aloe, which yields "sisal hemp" (*Agave rigida*, var. *sisalana*). The Director of the Royal Gardens, Kew, in June, 1891, kindly obtained a consignment of plants for the Calcutta Garden from Florida, and kept these at Kew till they were strong enough to stand the voyage to Calcutta. The boxes reached Calcutta on October 29th, 1891; unfortunately a considerable percentage of the plants died on the way out, and it was necessary to nurse the survivors carefully before they could be distributed. Over 19,000 specimens were contributed to the Herbarium during the year from various sources; while the distribution of authentically named specimens to other herbaria reached the high total of 10,505 sheets. The chief benefactor to the Calcutta Herbarium was again the Royal Herbarium, Kew, to the Director of which institution the Calcutta one "owes a debt that can never be repaid." Among other contributors was Baron von Mueller, who again sent a beautiful collection of Australian plants. The Herbarium was also greatly enriched by further accessions of Tibetan, Chinese, and Mexican specimens, and the Saharanpur Herbarium presented 954 plants from the north-west Himalaya. Dr. Prain visited the Andaman Islands, Mount Parashak, and the Khasia, and was thus enabled to add valuable collections. Much good work was also done by collectors employed by the Calcutta Garden.—("Nature.")

SUCCULENTS AT THE ABBEY PARK, LEICESTER.

SOME two years ago there appeared in the *Journal of Horticulture* a very good description of the Abbey Park. In main this holds good now, but there are many and great improvements on every side. The bedding is considerably altered, and that for the better. The annuals are in strong force and very fine. The carpet beds are fully up to date, while the subtropical garden has never before been anything like it is this year. The only regret is that something is not done in the way of providing a permanent house (as was spoken of by Mr. Owen Thomas at the last Show), so that these beautiful and interesting plants might be a "joy for ever," instead of, as is now the case, being packed away in the small houses with the bedding plants, and no one allowed to see them for

arrangement being avoided. This year the largest of the Agave species are planted in mounds on the lawn, and a more fitting place could not be found. As they stand some 7 feet high they would be far too large for bedding purposes.

It is quite impossible to number the occupants of the central bed, but it will be well under the mark to say that there are over 300 different varieties. The Agave tribe is well represented by some good specimens of *A. americana*, *A. variegata*, and *A. Celsiana*. Dotted about are many of the Aloes, of which *A. Noacki*, *A. Kellocki*, *A. linguifolia*, *A. ferox*, several really good plants of *A. Taylori*, *A. densa*, *A. densiflora*, and some beautiful little plants of *A. verrucosa* form a conspicuous part.

Opuntias are very numerous and in all shapes and sizes. *O. cylindricum* stands like a soldier on guard over a poor "old man," who is drooping his head rather near a Prickly Pear

FIG. 39.—BED OF SUCCULENTS AT THE ABBEY PARK, LEICESTER.

the greater portion of the year. There is one thing certain, that it will be totally impossible to winter some of the magnificent specimens of *Dracæna australis*, which play such a conspicuous part in the subtropical garden. Last year their pots were sunk in the floor, and even then their heads were pushing at the glass. There certainly should be no difficulty in procuring a house in which the summer Show could be held and these plants housed in winter, as the Committee have over £1000 in hand, which has been made at the gate on show days.

The accompanying engraving is a view of the succulent bed, which forms the centre of the subtropical garden. It is about 20 feet in diameter, and is composed of one of the finest collections of succulents in the kingdom. There are plants varying in height from half an inch to 5 feet or 6 feet, and from the tiny *Echeverias* to the stately *Agaves*. Stiff as the individual plants are, Mr. Burn has succeeded this year in putting them together in such a way that the stiffness is entirely done away with, all formality in

(*O. Rafinesqui*), which has many fruits: one bunch has grown on and on until some eight are hanging from one another. *Echeveria* is another genus which is in quantity; several *E. undulata* are flowering, as also *E. secunda glauca*, *E. Peacocki*, and *agavoides*. These deserve special mention, as do some very fine *E. metallica*.

As we near the border the smaller kinds are used, such as *Mesembryanthemum*, including the pretty and curious *M. tigrinum*. *Melonocacti* seem quite at home, and several have flowered during the summer. Some good tufts of *Crassula*, including *C. lycopodioides* and that strange "buttons-on-a-string" species, *C. perfoliata*. A number of *Rochea falcata* are distributed at intervals all round the margin. On the north side (*i.e.*, the back of the bed) there are several umbels of its gorgeous scarlet blooms, and occasionally we come across a fine specimen of creeping *Cereus*. The centre is beautifully carpeted with various small growing *Saxifrages*.

There are many kinds not named in the above list, but

sufficient has been said to show that this bed is well worthy of the reputation it has attained; and I will finish this little article by asking all visitors to the Abbey Park not to miss the subtropical garden, and above all the succulents.—W. BELL.

FUNCTIONS OF VINE LEAVES.

MR. DUNKIN argues well, and with great fairness. Evidently he is fully convinced of the soundness of his own theories, but he does not advance sufficient evidence in support of them to make me doubt the correctness of my own conclusions, however much they may be at variance with what experts have adduced. He takes it too much for granted that it is not possible to colour Grapes properly if the foliage beyond the bunches is not in a clean healthy state. Had he paid me a visit this season I could have shown him Madresfield Court as black as Sloes, and carrying good bloom, immediately over a hot flue, and red spider unavoidably in the ascendant. He would also have seen bunches with only a single primary leaf and two secondary ones that had larger berries than others where three, four, and five leaves had been left, the finish being about equal in each case. Who has not seen bunches left on a leading growth that had formed most disappointingly small berries, the finish also being nothing better than could be seen on short laterals? This may be an extreme case, but it is what first set me thinking. If growths 3 feet or 4 feet long thus robbed bunches instead of furnishing them with an extra good supply of elaborated sap, is it wide of the mark to conclude that it is possible to be too liberal in the matter of leaving primary leaves beyond the bunches? Those remarks on the functions of Vine leaves were penned long before they appeared in print. As far as the early and successional house is concerned my further experiments tend to corroborate my theories, and the late house still further strengthens them. The heaviest bunch of Gros Colman in the late vinery under my charge has no primary leaves beyond it, and only what secondary leaves have formed on the freely stopped sub-lateral growths. At present there is every prospect of this bunch colouring equally as well as the rest, but if it does not then I will readily admit I have made a mistake.

Mr. Dunkin writes concerning the advisability of allowing more primary leaves to form and sub-laterals to grow more unrestrictedly, much as though the practice was the making of some Vines and the salvation of the others. In describing what he saw a few years ago in a now famous vinery, he quite forgot to state how far apart the rods were trained, and I cannot help thinking he slightly over-estimated the weight of the crops produced. If the practice of leaving several leaves beyond the bunches, and of allowing the sub-laterals a free growth is to become general, then must those who adopt it be prepared to train their rods from 5 feet to 6 feet apart, and larger houses ought also to be the rule. Mr. Dunkin mentioned what he has seen practised with such good results, and is such a firm believer in the efficacy of the plan of allowing the Vines to grow far more freely than is usually done, that he will be surprised to learn the Vines in another famous vinery not unknown to him, and which have been for the past ten years or more treated exactly on the same lines he has described, have "gone wrong." They are not failures by any means, but no one could call them successes this season. As a matter of fact, this free growth of Vines may easily be overdone, and its value over-estimated. If regarded as a mere detail in an intelligent round of treatment it may answer well enough, but do not attach too much importance to it. In careless hands it may, perhaps, prove a "snare and a delusion." If it increases root-action it also necessitates more watering and more feeding, the greater expanse of foliage evaporating large quantities of moisture, while the borders soon become impoverished. Its adoption, therefore, means fewer Vines or rods, and fewer bunches, and greatly increases the labour and responsibility of the cultivator. I am treating on the subject now from a gardener's point of view, and not from that of a grower of prize bunches.

What I maintain is that Vines can be kept in admirable health and fully capable of producing heavy crops of superior produce when kept constantly stopped on the old lines, very little superfluous foliage being left. What with the foliage on the fruiting laterals and that on laterals between them, I hold that there is ample to meet all the requirements of the case. I have heard it repeatedly asserted that Vines are at their best when six or seven years old, their decadence soon after setting in. I can understand this being the case when the borders have been recklessly and early exhausted, principally or largely in the development of growth that has to be cut away, but it is not so where the treatment is more rational. The tenth crop of bunches on the Vines in our late house is much the best we have ever had, yet the stopping has been, according to Mr. Dunkin's views, too severe.

The colouring will be satisfactory enough, but something else besides good leaves is responsible for that.—W. IGGULDEN.

DISCUSSION ON APPLES.

APPLES IN THE NORTH.

THE behaviour of fruit trees this year has been decidedly erratic, and the Apple not the least so. It has been quite common to hear of gardens in the same locality with the widely different reports of "No Apples" and "An abundant crop of Apples." At the same time it is necessary to be guarded in receiving reports too literally, as so-called poor crops early in the season have swelled up into very good ones. In our own case the crop looked so very poor and unpromising that trees abundantly laden were only slightly thinned in order that the most might be made of what we had. But thinly set trees have done so well that the crop on the whole is a fairly good one, and freely set trees might just as well have been freely thinned.

The teaching of the present year once again emphasises the fact that young trees in robust health are the ones to depend upon for a certain fruit supply, and old trees are as a rule unworthy of dependance in any but a good fruit year. That, of course, is not the teaching we were brought up to, but it certainly is what the trees themselves proclaim. Again, it becomes palpably evident that the few select sorts are those to depend upon. If they do not bear an overflowing crop they set a sufficient number of fruits, and that in itself is a great deal when the chance of any crop whatever is a matter of uncertainty. Then I think it is abundantly evident that each district must choose its own sorts, and from these each garden. The peculiarities of soil have a striking influence. There are Apples which succeed only on heavy soils, and others which do best on light soils; while there are also soils of a happy medium character which produce any kind of Apple to perfection. No doubt also the individual peculiarities of some really good Apples require to be studied. Keswick Codlin is an example of a sort which may be spur-pruned year after year, and continue to thrive and be fruitful under the treatment. Irish Peach, on the other hand, prefers to be left alone, and under such conditions produces twins and triplets of beautiful fruit on the extreme points of its wilowy shoots. Others, again, of which Peasgood's Nonesuch may be mentioned as typical, are not averse to very drastic and recurrent root-prunings, while occasionally we find a sort assume a fruitful habit under a system of bodily removal.

As a rule, it does not pay to cultivate varieties requiring special treatment to induce fruitfulness, and it is wise to select only those which give the best returns with the least trouble. Generally these are also the best sorts. However, all young trees are improved by careful root-pruning as well as by removal. There is no good reason why either process should check the healthy growth of the trees, for if properly gone about it will not do so; but it will induce a more fruitful habit, and when once a young tree gets into a free-bearing habit, so long as overcropping is avoided, the habit will be perpetuated. A good time to prune the roots with good results is at the present time. If they are bare and long they are transformed into short, fibrous-bearing roots, and if they are already of a fibrous nature that condition is accentuated. An abundant crop of young rootlets is made before growth finally ceases—that is to say, ceases to all outward appearance, and the benefit to the tree will be apparent in the strong healthy blossom which results. The addition of fresh material for the young roots to lay hold of is of much value. Any fresh material is good, and the degree of goodness must of course depend on the ability of the grower to secure the best he can; but because one cannot secure loam, that is no reason why other soil should not be used, such, for instance, as the best contained in the general "old compost" depôt, which is often as valuable as loam.

The harvesting of the crop is a detail which will engage most attention for some time to come. Late varieties ought always to be allowed to hang as long as possible. Some of ours are left till November, but we are not often troubled with frosts before the middle of that month, a climatic condition which may not occur in every district. Where birds are numerous, and much given to fruit-eating, it sometimes becomes a necessity to gather the earlier ripening sorts before they are quite ready in order to save the crop. In some seasons we have to do this; but the better plan, where it can be carried out, is to go over the trees at intervals and gather the larger and better ripened fruits first, allowing the others a longer period on the trees to swell and finish. This system is not only productive of a larger size of fruit, but it is at the same time a means of relieving the trees, and also extends the season of any particular sort harvested in this manner.

It is almost too early to decide as to what to plant, but it may be of interest to add a note as to the varieties found most worthy of cultivating. I may begin with Early Julyan, which combines good cropping and cooking qualities with earliness. I like Keswick Codlin as a really reliable sort, one which in the worst of seasons bears a crop of fruit of good size and excellent quality, while the tree is absolutely healthy, and on our soil one of the few varieties which never show a trace of canker. Last spring I selected this for a pergola as being the best for the purpose. In a select collection I would pass over the beautiful Duchess of Oldenburg, as it keeps very badly, often in fact decaying during wet weather while still hanging on the tree. I would choose in preference to Lord Suffield for a light soil, on which it does not succeed, the newer Lord Grosvenor. This is not quite free from canker, but after testing it for some years I find it stands out so prominently from all others as a robust sort, combining extraordinary

cropping qualities with size and good flavour, that I do not think any other Codlin approaches it. Ecklinville and Warner's King are two indispensable varieties for all qualities of soil, Stirling Castle and Cellini for heavy soils only, and the same remark applies to Pott's Seedling. The Queen is a beautiful variety, and does well on a light soil. Extra good also is Gascoigne's Scarlet, a noble looking fruit, which keeps well but must hang a long time on the tree. Of later varieties, those which always do well here are New Hawthornden, Frogmore Prolific, Northern Greening, New Northern Greening, Mère de Ménage, and Alfriston. With the exception of the Greenings, these are all of large size. If a small cooking Apple is required King of the Pippins ought to be selected. Blenheim Orange and Dumelow's Seedling do not succeed, but on a heavy soil they are standard sorts.

Dessert varieties ought to include Margaret, for eating off the tree, Irish Peach, Mr. Gladstone, Kerry Pippin, Ribston Pippin in quantity, Cox's Orange, and any soft sorts that on trial do well. As a rule late hard Apples do not come to much in the north except when trained to a wall.

As to planting the trees, do not order them until they are wanted, and when they come to hand plant them at once. If any unforeseen circumstance hinders planting keep the roots moist with damp litter until wanted. Nothing harms trees more than to keep shifting them about before planting. I got a good number of young trees last April, which on arrival had their roots dipped in a solution of soil and water, were then planted at once with some good compost about the roots, watered twice during dry weather, and all have done well. If they had been lifted sooner and laid in by the heels until wanted, the result would have been very different.—R. P. BROTHERSTON.

EMPEROR ALEXANDER.

THIS is a most desirable culinary Apple, being a good grower and a free cropper. The fruit is very large and of handsome outline, with a large eye deeply sunk in an evenly formed cavity and streaked with red on the side next the sun, the quality being such as to render it eligible for table use. Young espalier-trained trees are doing well here, and established trees, similarly trained, annually bear fine crops of extra fine fruit in the Palace Gardens, Salisbury, in which gardens Mr. Fred. Smith, the Lord Bishop of the Diocese's excellent gardener, grows several approved varieties of the Apple to perfection.—H. W. W.

STIRLING CASTLE.

I HAVE to-day, September 22nd, gathered some fine fruits of this handsome free-bearing Apple, the largest of which turned the scale at 12 ozs. The tree is a good grower as well as a free cropper, characteristics not to be lost sight of in fruit trees of every description.—H. W. W.

ST. EDMUND'S PIPPIN.

IN looking over Messrs. Veitch's Southfields nurseries the other day I came across this Apple for the first time, and think it should be more generally known. Young trees, two years old, are covered with good fruit above the medium size, and the flavour is much better than that of any Apple I know at this season. It was raised by Mr R. Harvey, Bury St. Edmunds, and received a first-class certificate from the Royal Horticultural Society on October 6th, 1875. It was described as richly flavoured, medium sized, resembling the Golden Russet, and ripe now. Growers who want a highly flavoured, free-bearing Apple should look out for this. Of course it must be on the Paradise stock.—H. HUNTLEY.

KESWICK CODLIN.

I CAN certainly corroborate Sir John Sinclair's statement respecting this good old Apple—viz., "that it flourishes best on strong soil." At least it is highly satisfactory here, and ours is a very strong soil, resting on a thick stratum of close, almost impervious, clay. We have two trees of this variety at least fifty years old, which to my knowledge have only failed twice in eleven years to carry full crops of large clean fruit. During this time the trees have never had the least attention either with regard to pruning or manure. When renovating an old orchard here, in the autumn of 1890, we planted a maiden standard of Keswick Codlin on one of the stations, which had been previously well prepared. In the following spring all the shoots were cut back to well situated buds at the base, and by the following autumn the tree had made ten shoots from 30 to 36 inches long. This season's growth has been equally free, and it has all the appearance of carrying fruit next year. Possibly "E. M." could trace the failure of this variety with him to a chemical rather than a mechanical condition of his soil.

BESS POOL.

The advice so freely given a few years ago respecting the limitation of varieties should be carefully practised, for experience proves that free, regular-bearing varieties are sometimes rendered barren through uncontrollable atmospheric conditions, and that is the case in many localities this season. Bess Pool has the best of qualities as an Apple, but owing to its irregularity in bearing it should not be planted largely. We have, however, often found it exceedingly useful in seasons of scarcity like the present, owing to the fact that it blooms at least a fortnight later than most varieties, and thus escapes the late spring frost. It is recorded in Dr. Hogg's "Fruit Manual" that "one season, when Apples were scarce, the fruit of seven trees sold at 7s. 6d. a peck, and made £70, or an average of £10 a tree." It would thus seem that this variety is often found bearing in scarce seasons. It is a strong grower, and does not bear in a young state, even as cordons on the Paradise stock.

COX'S ORANGE PIPPIN.

We have a dozen bushes of this variety on the Paradise which have not failed to bear heavy crops every season during the last ten years, and this season is no exception, for the trees are loaded. They are just as free as upright cordons on the same stock planted by the sides of walks. Being so free the trees have to be deluged with manure water from the farm at all seasons or their fruit would not swell to half the proper size. This is a first-rate Apple, both for cooking and dessert; it keeps plump and good to the end of May. Cox's Orange Pippin is the very best variety to grow as bushes and cordons in small gardens, and for cottagers who may only have room for one tree it would be difficult to name a more reliable sort. It is a pity every cottager in the kingdom does not know of its great merits. They should be careful to have plants worked on the Paradise or they may be disappointed.

ANNIE ELIZABETH.

This is a comparatively new variety, sent out, I believe, by Messrs. Harrison & Sons, Leicester. We planted a standard in the orchard four years ago, and have found it a very free bearer except this season. The fruits are very handsome, being of a very bright crimson on the side next the sun, which secures for it a full share of admiration. The fruit is about the size of Stirling Castle, and much resembles that variety in general outline. It is a first-rate cooking Apple, but is rather too sharp and brisk for most people to be used for dessert, unless it is to make an ornamental dish.

LORD GROSVENOR.

This fine cooking Apple is well adapted for growing as upright cordons by the sides of walks when grafted on the Paradise. Grown thus they bear regularly right to the ground, and the fruit swells to a very large size. The fruit is more sheltered from high winds than when grown as bushes or standards—a circumstance of great advantage with all large fruiting kinds.—J. H. W., *Leicester*.

KING HARRY.

So far I have only seen this new Apple in fruit at Maiden Erleigh, where Mr. Turton has it fruiting well, and so pleased is he with it as a midseason dessert variety that he classes it with the very best sorts. The fruits bear some resemblance to those of Cockle's Pippin, but are much larger, brighter, and handsomer; the eye is more open, and the base of the fruit rather broader and flatter. The skin when ripe is of a bright yellow, orange next the sun, and is dotted with russet spots something after the style of Wyken Pippin. The tree is a very good grower, and crops well. The fruit is in season in November. It is also of crisp white flesh, and good flavour. It will not be a matter for surprise if this variety should shortly make a good reputation as a dessert Apple. Mr. Turton will probably show a sample of the fruit at Earl's Court on October 5th.—A. D.

LADY SUDELEY.

REFERRING to my remarks on page 238 as to the Irish Peach, I have to state that Messrs. Geo. Bunyard & Co. of Maidstone, the famous Kent growers, very kindly sent me half a dozen fruits of their new Apple Lady Sudeley, and I must, in justice to them, say that the fruits were lovely specimens, perfect in shape and "finish," and have been admired by everyone who has seen them. It is a remarkably handsome Apple with a powerful aroma, and although in the specimens sent me not quite so juicy and crisp as Irish Peach, they may possibly have been a little too ripe and past their best, which would account for their being somewhat soft, a fault nearly all early Apples have if not plucked and eaten almost direct off the tree. In my opinion Lady Sudeley is an Apple that has "come to stay;" its beauty will make it a favourite on the exhibition table, whilst its soft flesh and strong aroma commend it to all who do not like an Apple which requires much mastication, and leaves, as many Apples do, a lot of indigestible "wood" behind.—F. BOYES, *Beverley*.

IRISH PEACH.

I CONSIDER this the best of the early dessert varieties in flavour, and I see it is regarded in the same light by others. With us it is a sure and heavy cropper, but I am told it is not a good market Apple. The colour is not what could be wished for that purpose; this shows the fallacy of public taste, in some things at any rate. It requires care in pruning, as it bears mainly on the points of the shoots, and to obtain a full crop every year the spurring system should not be always or wholly adopted. I was not a little surprised this year to find a full crop of fruit on some young trees planted in the autumn of 1890, and which were subjected to 7° of frost one night while the trees were fully in bloom, still no harm appeared to have befallen the blossom, although the pistil was black right to its base.—E. M.

NOTES FROM BEVERLEY.

KESWICK CODLIN is a very old sort much grown about here, but although it is a good bearer and an excellent cooking Apple the tree has a somewhat sickly look and carries a quantity of small spotted fruits. In a few instances it is healthy and bears fair sized fruits. It is, however, a variety which has been superseded by better kinds. Pott's Seedling is an excellent early cooking Apple, clean, healthy, and the fruit of good size and shape. It has fine foliage somewhat like Lord Grosvenor, and one of its best properties is that it cannot be blown off. I have known a tree perfectly laden with fruit withstand a gale of wind without losing a single Apple, whilst the neighbouring tree, Cox's Orange Pippin, has been nearly stripped of its unripe fruit. When eaten from the tree Pott's is very juicy and refreshing, although a kitchen Apple. Duchess of Oldenburg is often classed as a dessert

kind. It is a very prettily striped early Apple and a capital bearer, but as grown here not good enough for dessert, and for cooking has to compete with others of the same season and superior to it in size. Ecklinville Seedling is one of the most certain croppers we have, and on the Paradise stock produces very fine fruit. Lanc's Prince Albert, another excellent cropper, the fruit clean and keeping a long time, is one of the very best. Stirling Castle is another of great merit. It is an abundant cropper, and the fruit is smooth, clean, and good. The last three and Potts's Seedling are four of the best and most reliable cooking sorts grown for garden culture; Lord Grosvenor and Lord Derby may be added to make up the half dozen.—F. BOYES.

NOTES ON THE EARLY VARIETIES.

(Concluded from page 265.)

I WILL now leave the historical and descriptive side of my subject and turn to practical matters. First comes propagation. In this as in other phases of culture the same method is not practised by all cultivators. In looking through some back volumes of the *Journal of Horticulture* the other day I came across a small paragraph on the subject, in which a mode of propagation is recommended which, whatever may be its merits otherwise, has certainly to my fancy reached the acme of simplicity. In the issue for March 29th, 1888, page 265, Mr. J. Muir, Margam Park, writes:—"In my opinion these are the most useful plants in the flower garden. They are hardy and so easily managed that any novice may succeed with them. They flower freely in all situations. They grow well in towns under the direct influence of smoke, exposed to the sea breezes, under the shade of trees, and in positions where flowers do not generally succeed. These Chrysanthemums prove gay and attractive under all circumstances. They begin flowering about the end of June and continue to do so until frost destroys them. When we had our first plants we propagated them in heat in spring, but when once the plants were established in the open we ceased to propagate indoors, and now allow the plants and roots to remain in the ground all the winter, lifting them in April, dividing them into small pieces with a root attached to each, and replanting. This is our practice when we wish to increase them. If not they are allowed to remain in the same positions."

There is no doubt the above simple method answers very well in the locality where Mr. Muir is happily placed, the fertile Vale of Glamorgan, where the cold winds and frosts of winter are tempered by the warm breezes from the Bristol Channel. He may undoubtedly safely leave out his whole stock in the open ground all the winter, but in Leicestershire, had we tried the same course during either of the last two winters, we should certainly have found it necessary to start with an entirely new stock in the spring. As a general rule to follow none is better than that recommended by a large cultivator as follows:—"They are best taken as cuttings from plants that have been wintered in cold frames early in February. After they have been potted off and have commenced to grow they should be stopped. After this they will branch freely, and it is best not to stop them any further. They should be planted out in April."

If large bushy plants are desired cuttings should be taken in December of the Pompon varieties, and in November of Madame Desgranges and its sports. These are potted singly in large 60's in December or January, and stopped, as above stated, a week afterwards. About the end of February or early in March they will require a shift into 48's, and a second pinching or stopping should be given a week afterwards, planting them out in April. Plants so treated will be strong and well established at the time of planting, growing with vigour as soon as planted, and flowering well at their proper season. Growers for market, however, usually prefer the shortest course, and thus the plan of propagating in February commends itself to them, not only on account of the much shorter time and less labour taken up, but also on account of the smaller amount of space occupied, this being very valuable in houses and frames during February. When propagated in February one shift only into 60's is required, and from these they are planted out. After planting see that the hoe is frequently used amongst the plants, not only to destroy weeds, but to promote rapid growth.

If the plants are to be lifted especially for potting care must be observed not to allow them to become too far advanced ere it is done. The best time, the plants suffering least, and recovering most quickly from the effects of the operation, is as soon as the buds are formed, and are as large as peas. Lift them carefully, pot them quickly in light rich soil, water them, and place them for a few days in moist shady quarters, such as on the floor of a greenhouse immediately under the side stages, so that they are shaded from sunshine. Syringe them twice daily—morning and evening—thus keeping them moist, cool, and shaded. These conditions should suffice to prevent them flagging, and in little more than a week they will bear full exposure to light and air. When the plants are grown for the production of flowers for cutting only it is better not to pot them, but to lift them with as large balls as can be

secured, and pack them moderately closely together on the floor of a cold frame, or on the stages of a greenhouse, covering the roots with fresh soil as the work proceeds. I have used for this purpose a house where early Cucumbers have been grown, simply pulling up the Cucumber plants and using the soil in which they had been growing for covering the Chrysanthemum roots. Excellent flowers may also be obtained by leaving the plants out in the open garden, and placing frame lights over them to protect the flowers from frost and rain.

In average seasons large quantities of most useful flowers may be cut from the plants in the open garden without any protection whatever, and during the time I was at Oakbrook I made a point each season of having a large bed especially for this purpose. A few words will suffice to explain the most profitable method of doing it. A considerable portion of the plants which have been flowered in pots should be cut down after their flowering season is over and placed in cold frames—firstly, for supplying what cuttings are required, as before mentioned; and secondly, for planting out to furnish flowers for cutting from the open ground. They should be kept in the cold frames until early in March, when they may be placed outside under a south wall, turning them out of the pots and planting them on good ground 2 feet apart early in April. They should not be stopped, but be allowed to produce all their growths freely and unchecked from the first. They will thus make large dense bushes, coming into flower earlier than the younger plants, and in a favourable season producing an astonishing quantity of useful flowers throughout September and October. After the flowers are gone they should be destroyed, and a fresh lot of one-year-old stools be planted annually in April.

The small-flowered or Pompon varieties of summer-flowering Chrysanthemum do not, as a rule, succeed well if cultivated in pots throughout the season. I have in past years tried them fairly and well on more than one occasion, but have invariably found that those cultivated in pots were much inferior to those which had been planted out. The larger flowering varieties, however, such as Madame Desgranges and its family, are frequently grown in pots throughout, and under good cultivation they will give better results in this manner than if planted out. For this purpose the cuttings should be taken early in November, and the plants be grown on the shelf of a cool house through the winter, shifting them as required, and stopping them twice, as mentioned before. That useful variety, Grace Attick, is also, I find, best kept in pots throughout. It grows freely and vigorously when planted out, but bears lifting very badly, the result, as a rule, being that most of the flower buds perish or fail to open satisfactorily.

I will conclude by giving short lists of varieties most suited for the various purposes for which these early flowering Chrysanthemums are cultivated. The following are suitable for lifting and potting, either for market purposes or home decoration:—Whites: Mdme. Desgranges, Mdle. Jolivart, P. Radaelli, Mrs. Cullingford, and Nanum. Yellows: Flora, Mrs. Hawkins, G. Wermig, Mrs. Burrell, Golden Shah, and A. Crepey. Purple, Red, and Pink: Salter's Early Blush, Blushing Bride, Alice Butcher, Miss Davis, Fred Pélé, and Lyon.

The following are suitable for producing cut flowers when lifted and packed together in frames or houses but not potted:—Whites: Mdme. Desgranges, Mrs. Cullingford, Mdle. Jolivart, Sœur Melanie, and La Vierge. Yellows: Mrs. Hawkins, G. Wermig, Flora, Fiberta, and Précocité. Purple, Red, and Pink: Alice Butcher, Miss Davis, Mr. W. Piercy, Lyon, Mdme. Foucher de Cariel, Mdm. Piccol, and Roi des Précoces. The last-named, however, can scarcely be termed summer flowering.

The following are good for outdoor decoration and for cut flowers as grown in the open air:—Whites: Nanum, Mdme. Desgranges, Mdle. Jolivart, and Mrs. Cullingford. Yellows: All the Desgranges sports, Fiberta, Flora, Précocité, and Golden Shah. Purples, Reds, and Pink: Alice Butcher, Miss Davis, Fred Pélé, Lyon, Mdme. Piccol and its sport, Mr. W. Piercy.

The following are good for pot cultivation throughout:—All the Desgranges family, Mdme. Foucher de Cariel, Grace Attick, and Mrs. J. R. Pitcher.—W. K. WOODCOCK.

FRUITS AND FLOWERS AT THE WORLD'S FAIR.

THE horticultural display at the Chicago World's Fair will, we are told, be bewildering in extent and marvellous in beauty. The exhibit will possess great scientific and educational value, but to the ordinary visitor its ornamental features will be the most striking. Indeed, it will play an important part in the adornment of the great Exhibition. While in almost every part of the grounds may be seen gratifying evidences of the very efficient work of the Horticultural Department, the central point of interest will naturally be in the exhibit in the horticultural building. This structure is 998 feet long and has an extreme width of 250 feet. Its plan is a central pavilion with two end pavilions, each connected with it by front and rear curtains, forming two interior courts, each 88 by 270 feet. Surmounting the central pavilion is a beautifully proportioned dome, 187 feet in diameter and 113 feet high.

VINES AND WINES.

In the south pavilion of the building will be installed the viticultural exhibit, embracing all varieties of wine and everything pertaining to its manufacture. An idea of how complete this part of the exhibit will be can be gained from the fact that applications for space have already been received from thirty-three foreign countries. From abroad the

exhibits of France, Germany, Spain, and Italy will be especially notable. A fine exhibit of Chilean wines and raisins, famed for their superior quality, will be made. California will make a splendid display, all of the great firms being exhibitors, and having applied for much more space than can possibly be allowed them. If permission, which has been asked, be given, Senator Stanford will exhibit a wine fountain. This, as planned, will throw, for two hours each morning and afternoon, graceful streams of wine to the height of 22 feet.

FRUIT.

In the rear courts of the building will be shown the fruit exhibit, which will include all varieties grown in any part of the world. As far as it is possible to do so, probably in a great majority of cases, fine specimens of the natural fruit will be shown, otherwise wax models, so perfect in appearance as to be indistinguishable from the real fruit, will be substituted. For this exhibit about 44,000 square feet, or more than an entire acre of space, is reserved. A very complete and splendid exhibit of Citrons and other fruits will be sent from California, Florida, Mexico, and South American countries. By means of refrigerators ripe fruit can be sent long distances without injury, and after reaching the Fair cold storage facilities will be available to keep it in perfect condition.

SHRUBS.

The exhibit in the important line of floriculture will be exceptionally extensive, and the preparation of it is far advanced. Unless this were the case the exhibit could not well be a success, for time is required for plants to overcome the check received in being transplanted. More than 500,000 transplanted shrubs and plants, of many species, are now growing in the grounds, and the number is rapidly increasing. The department sent out circulars to prominent horticulturists and horticultural societies in all parts of the world, requesting donations of plants, and agreeing to permit the name and address of the donors to appear in connection with such specimens as they might send. The result is that thousands of plants—excellent specimens, too—have been forwarded. Among them are more than 50,000 rare Rose plants, which have been sent by firms all the way from California to Hungary.

ORCHIDS.

The floricultural exhibit will not be concentrated in one place. In the front of the building will appear the greenhouse and hothouse plants—a very large variety, and many rare and beautiful specimens. There, too, will be the finest display of Orchids ever seen in America, if not in the world. One firm alone will spend 40,000 dollars on its Orchid exhibit. At the opening of the Fair, Chief Samuels says, there will be a display of 2000 different varieties of Orchids, embracing fully 15,000 specimens. Beneath the great dome will be the largest tropical plants obtainable, including Japanese and Chinese Bamboos 75 to 80 feet high, Palms 30 to 40 feet high, and Tree Ferns 15 feet or more in height. There will also be a miniature mountain covered with tropical plants, and in a cave within will be tried the experiments of growing plants by electric light and of growing them by the aid of electric currents, passed through the soil, both of which, it is claimed, have been accomplished with remarkable results.

ORANGE GROVES.

The two courts of the horticultural building will be filled with Orange groves from California and Florida respectively. In each there will be not less than 160 trees, each bearing about 200 bright, ripe Oranges. Thus an interesting comparison may be made between the Oranges of the two States as to size and flavour. The courts will also contain growing specimens of Lemons, Limes, and Bananas. California would like to make a much larger display than will be possible, and applied for about fifty times as much space as could be assigned. It will occupy an acre on Midway Plaisance with a Citrus exhibit. On the Plaisance, too, five acres will be devoted to a nursery exhibit, and Wisconsin will show there a Cranberry marsh. Six acres in front of the horticultural building will be devoted to the floricultural exhibit, as will also space about many of the larger buildings.

SIXTEEN ACRES OF FLOWERS.

The "wooded island," or, as more properly named perhaps, the flowery island, will be one of the most beautiful and attractive spots at the Exhibition. It embraces between 15 and 16 acres, and has been turned over almost entirely to the horticultural department for its exhibits. There, literally speaking, will be acres and acres of flowers of brightest and most varied hues and pleasing perfume. Little groves of trees, clumps of shrubbery, and sinuous walks will relieve the gorgeous monotony of this floral display. On the north end of the island Japan will build its strange antique temple, and surround it with the choicest plants and flowers of the island realm of the Mikado. At various turns of the winding walks which thread this delightful domain of flowers the visi or will encounter artistic little structures of the summer-house description, within which one may seat himself, and enjoy rest and beauty and perfume. Many of these retreats—sixteen or eighteen in number—will have thatched roofs, and be covered with growing Vines, and otherwise ornamented—in keeping with their beautiful surroundings.

In the north pavilion of the horticultural building will be a very extensive display of vegetables, canned goods, horticultural appliances, &c. In the second storey of each pavilion will be a restaurant capable of seating about 200, and profusely adorned with Ferns, flowers, and exotic plants. Outside will be a number of greenhouses, where visitors may see an exceptionally complete collection of tropical vegetation. There will also be large auxiliary greenhouses, not open to the general

public, where plants will be brought to perfect exhibition condition, and where plants will be cared for after their beauty has passed.

INSECTS.

It may be rightly inferred that the horticultural exhibit at the Exhibition will be the most complete and extensive ever made or attempted. It is certain to attract a great deal of attention and prove to be of great scientific and educational interest. It will have important features not specified above, as, for example, a very complete collection of insects, both the injurious and the beneficial ones, whose operations affect the fruits and other products of the horticulturist. It is the intention to have in one place an exhibit of all of the species of plants mentioned in the Bible, and in others collections of almost equal historical interest.

Both Chief Samuels, who has general charge of the Horticultural Department, and Chief Thorpe, who looks after the floricultural division of the exhibit, have proved themselves to be the right men for their respective duties, and it is already assured that the display which, with the active and generous aid of horticulturists the world over, they will furnish will be long and pleasantly remembered by everyone who visits the World's Fair.

AOTUS VILLOSA.

OPINIONS appear to differ as to the likelihood of a revival of the Cape and New Holland plants, which were once so highly esteemed. The popularity of Orchids will in all probability ever be a powerful

FIG. 40.—AOTUS VILLOSA.

impediment to such a consummation, beautiful and useful as many of the plants admittedly are, for in many places too much space is given to the Orchids to allow of room for anything like a representative collection of hard-wooded plants. Messrs. Low & Co. exhibited a number at one of the Royal Horticultural Society's spring meetings, and many of the plants shown were greatly admired. Wherever a collection is formed *Aotus villosa*, which fig. 40 represents, should be included; indeed, all the members of the genus are worthy of cultivation. *A. villosa* is an attractive, compact, much-branched shrub. The flowers are bright canary yellow, the standard streaked with crimson lines. It blooms in May and June. *A. gracillima* is a slender, graceful species with bright yellow flowers, which are produced in such profusion as to entirely hide the leaves, leaving the slender stems like long racemes of flowers. Both plants invariably delight those who see them in good condition. They succeed well in peat and loam in equal parts with a good portion of sand added.

LIVERPOOL NOTES.

THINGWALL HALL.

WHILST paying a visit to this beautiful country house recently I was agreeably surprised to find such a magnificent collection of herbaceous and rockwork plants, which fill two borders, each 70 yards long. Everything that is good and worth growing finds a home, and in Mr. Foster, the head gardener, they have one who not only thoroughly understands their wants, but is able to speak of them in a manner that all lovers of those beautiful flowers would delight in. Though having been tossed about by the storms of the past few weeks, there was much to interest one. Charming varieties of Veronicas, some with delicate spikes and

dwarf habit, others with bolder habit and more pronounced colouring; Anemones in variety, lighting up the whole length of the border; Galtonia (Hyacinthus) candicans with its tall spikes of white flowers; Statice latifolia and Gmelini, always interesting; the Solidagos with their yellow spikes, fit companions for the blue Veronicas; Tradescantias, Hypericums, Phloxes, the lovely little Polygala chamaebuxus, with its quaint but delightful fragrance; Colechicum autumnale in clumps, masses of flower; Sedums of almost every variety, and many more plants were in full beauty. It is Mr. Foster's intention to thoroughly overhaul the borders this season and re-arrange them. It will be time well spent both as regards the benefit the plants will derive and as respects keeping them correctly named. With the mention of three charming beds I must leave the remainder of the many good things I saw at Thingwall for another time. As we walked round the pleasure grounds a bed filled with Rosa rugosa, having great bunches of beautiful berries and many flowers, standing alone, was most attractive. Another bed in a nook surrounded by shrubs was filled with Tritoma Uvaria, and a little farther on in a similar position was a third with Anemone japonica alba. None of these is difficult to grow, and they appeared doubly welcome, isolated as they were from all other plants.

ROBY MOUNT, ROBY.

The most successful Blackberry culture that I have seen in this neighbourhood is to be met with here. A wall adjoining the embankment of the L. & N.W. Railway, and too low for cultivating Apples, Pears, Cherries, or fruits of that description, had some two years ago a plant of the hedgerow Blackberry and one of the Parsley-leaved planted, so as to make a covering. Just the ordinary soil was used. Since then they have grown with amazing rapidity, and now cover a great many yards of the wall. They have been picked over five times up to the present, and the crop is enormous, hanging in massive bunches all over the plants. The fruit is of the finest description, and likely to keep on ripening until the frosts cut it short. The value of a crop like this, especially at this season, when Raspberries and other fruits are over, is very great. As cultivated at Roby the common variety is both larger in the berry and of much better flavour than the Parsley-leaved. It was a happy thought of Mr. Eaton to plant the Blackberries, and one which must give the greatest satisfaction to his employer, John Parrington, Esq.

Who would be without Carnations when they can be had in full flower in five months from the time of sowing the seed? This was my thought when Mr. Eaton pointed out to me a sturdy collection of plants of the dwarf Marguerites full of flowers and buds, some of which he picked for me, the colours comprising white, salmon, rose, maroon, pink, and terra cotta. They are prettily fringed and deliciously scented. The seed was sown about the middle of March, and placed in heat. When large enough the seedlings were pricked off into boxes filled with rich soil. The middle of May saw them placed a foot apart in a south border, and in August they were in bloom. For gardeners, nurserymen, or cottagers the Marguerite Carnations will prove of inestimable value.

CLEVELEY, ALLERTON.

If things go on in the future as they are at present we shall soon see Cleveley famed for its Lapagerias, which are just now very beautiful. Of the three original plants alba and rosea superba occupy the west side of the roof of a house for a length of 25 feet, whilst the variety rosea, which is very much inferior to the other, is planted in the same border, and covers the gable end of the house for a space of 20 feet. To stand at one end and view the whole, intermingled as they are, is to receive a most refreshing impression. The border in which they are planted is underneath the side stage of the house, the soil being composed of peat three parts, charcoal, crocks, and sand. As the growths appear they are protected from the attacks of slugs by having Cucumber glasses placed over them, which are retained until the young shoots possess a certain amount of solidity. In the long corridor, which is just now gay with Bougainvilleas, Plumbagos, Tropæolums, and Roses on the back wall, and running up to the roof so that the sprays hang down gracefully, and the narrow side stage filled with the best varieties of Tuberous Begonias, is another newly planted border of Lapagerias, many growths being as thick as a good sized cane. The cultivation of Blackberries is being taken in hand on a large scale. An iron arch many yards long has been fitted up with the Parsley-leaved and Wilson, jun., varieties planted on each side. It is filling up rapidly, and a very fair crop of fruit is ripe and ripening on the former, but Mr. Cromwell fears the latter variety will be too late for this district; perhaps in a good season it may do better.

HUYTON AND ROBY—WITH WHISTON—HORTICULTURAL SOCIETY.

At a special meeting of the above Society, held a short time ago, the question of appointing two Judges to judge the cottage gardens, came before the meeting, the result being that Mr. R. Pinnington, gardener to Mrs. Banner, Blacklow House, Roby, and Mr. T. Eaton, gardener to John Parrington, Esq., Roby Mount, Roby, were deputed to undertake the task, and report to the Committee their decision. At a meeting held last Thursday, presided over by G. G. Musson, Esq., the report was presented, and read by the Chairman. Mr. J. Read, Kennel Cottages, Whiston, was unanimously awarded first honours for a well kept garden throughout, Mr. Samuel Davies, the same address, being a very good second, and Mrs. Helsby, Roby, third. There were four others recommended for their clean and neat appearance, and as an encouragement the Judges recommended that small sums should be awarded to them, a suggestion which the Committee readily acted upon. Subscrip-

tions are coming in very freely, and everything points to a most successful Exhibition of Chrysanthemums, fruit, and flowers in the Huyton Park Hall on Saturday, November 12th. The Secretary, Mr. J. Taaffe, is doing very good work.—R. P. R.

EPIPHYLLUMS.

EPIPHYLLUMS are charming and exceedingly useful plants, adapted for various decorative purposes and positions under glass. They do not grow very fast, and are in consequence very serviceable for decorating either large or small plant houses. For growing in pots the general system adopted for Epiphyllums is to graft them on stocks, Pereskia Bleo and P. aculeata being the best and most generally used. Cuttings of these strike readily in heat; they should be inserted in very sandy soil at any season, and should afterwards be potted and grown until they have reached the required height. Good sandy loam to which a little brick rubbish has been added will form a very suitable compost for them. Grafting is easily performed, as it merely consists in obtaining a small branch of Epiphyllum just as the growth commences in the spring, afterwards opening the stock at the top or at any part of the side that is sufficiently hard, inserting the branch, and passing one of the sharp spines from the Pereskia right through to hold all firmly. Young plants may also be readily obtained by taking short cuttings, inserting them in small pots, and placing them in a propagating frame; but this method is not much practised except for use in baskets or any position where they are intended to hang down, the branches being unable to support themselves in an upright position when growing, owing to the dense trailing or pendent habit.

It is for decorating the roofs or pillars of houses having an intermediate temperature that I more especially wish to draw attention to the Epiphyllums, as there is nothing more effective during the flowering season. Pereskia Bleo forms the most suitable stock for this method of cultivation, as it is a much stronger grower than P. aculeata. Cuttings should be inserted as previously advised, and when rooted should be potted till they have reached the required height, when they should have their leader removed and the grafts inserted as before mentioned. When used as a decorative plant for pillars it is advisable to plant two stocks at each pillar and train them round it in an opposite direction to each other, as by so doing a much quicker and better effect can be procured than by only planting one, in consequence of the Epiphyllum being, as I said before, of such a slow growing nature. When grown on a roof a charming display may be produced by associating it with the Stephanotis. The best way to accomplish this is to train it at intervals in an upright position across the Stephanotis, the latter making a beautiful background of green to the lovely scarlet of the Epiphyllum. It is by no means detrimental to the growth of the Stephanotis, and by training the stocks on the underside the Epiphyllums hang gracefully down and have a fine effect.—G. PARRANT, *Ashby St. Legers Lodge, near Rugby.*

CALIFORNIAN PRUNES.

SOME interesting particulars are given by Consul Donohoe of San Francisco on the subject of the cultivation of the Prune in California. It is to France that California is indebted for this healthful and profitable fruit. Louis Pellicier, a French sailor, arrived in San Francisco in 1849, and went to work in the mines in Trinity County. He did not succeed well there, and finally removed to San José early in the fifties. Here he established a nursery. He soon after induced his brother Pierre to join him in California, and the two brothers worked the nursery together until the spring of 1856, when Pierre returned to France in order to marry a girl to whom he was engaged. Combining business with pleasure, he secured a large number of cuttings of Prunes, Grapes, and other fruits, which he brought back with him on his return. The Prune cuttings were procured in the Villa Neuve d'Agen, from whence the common Californian Prune derives its name of "Petite Prune d'Agen." They were carefully packed in a box about 16 inches square by 4 feet in length, which was lined with cloth, and every precaution was taken to insure the safe arrival of what has since proved the germ of one of the most important industries of California. The importance of Pellicier's experiment was not appreciated for about a quarter of a century after he began it, but at length the superiority of California as a fruit-growing State forced itself upon public attention, and the Prune was given a trial. From that time the growth of the industry has been phenomenal.

The Prune, says Consul Donohoe, is a very hardy tree, and will grow where the thermometer touches zero. Its favourite habitat, however, is a temperate climate, with a warm generous soil. It is estimated that in California, in Santa Clara county alone, when the trees now growing shall have matured, the annual product will be over 40,000,000 lbs. of dried fruit. The most extensive single Prune orchard in the State is now in the Salinas Valley, in San Luis Obispo county, on the eastern slope of the coast range, near the town of Templeton. In this orchard there are nearly 300 acres of Prunes in one body, containing 324,000 trees. The first Prunes were grafted on Plum stock, but this has grown into disfavour on account of the tendency of Plums to throw out suckers, and other stocks, the Peach, the Apricot, and, lastly, the Myrobalan Plum, have come into use. The principal markets for California Prunes are Chicago and New York. The quantity now consumed in the United States is enormous. It will be years before the demand on the other side of the Atlantic can be supplied, and when that shall

have occurred there will be the markets of Europe and the rest of the world to supply, for the California Prune is said to be superior to the French Prune in flavour, while it will keep better and longer without sugaring than the latter.

PHILIPHAUGH, N.B.

THIS beautiful estate adjoins that of the Duke of Buccleuch in Selkirkshire, and the mansion commands a fine view of Bowhill and the surrounding country. The classic stream of Yarrow runs in front of the house and lends an additional charm to the surroundings. Philiphaugh, long the property of the Murrys, was purchased from them some four years ago by W. S. Steel, Esq., and with characteristic thoroughness he has gone in for making an entirely new garden, where everything may be had of the best. Four splendid ranges of glass houses have been erected in the kitchen garden, and a magnificent conservatory is just being completed adjoining the mansion.

The first range entered is 160 feet long, 13 feet high, 16 feet wide, three-quarter span. It is in four divisions, three being devoted to Vines and one to Peaches and Nectarines. The first division is planted with Black Hamburg and Foster's Seedling, the second is planted with Muscats, and the third with Gros Colman, Alicante, and Lady Downe's. The back wall is covered with Vines bearing fruit. The Vines planted in the front are being allowed to grow and ramble as much as possible. Planted in July, 1891, they had much to contend against in that they were attacked by wireworm, which abounds in the turf in Selkirkshire. Thousands were trapped and killed, and gradually the Vines made headway against their enemy. When rid of their foe they will no doubt make splendid canes. The fourth division in the range is devoted to Peaches and Nectarines. The best varieties are being cultivated, and all the trees looked well. In addition to the Vines and Peaches this range contained a large number of Tomatoes in fine fruit, and a choiced display of Adiantums, looking as if they were at home, also some very fine early Chrysanthemums with splendid blooms.

The second range entered is in six divisions, span-roofed. The first contained Melons on the front and Cucumbers on the back, all doing splendidly; beneath them many things were being propagated, so that no space was lost. The second division was similarly occupied. The third division contained a grand lot of Eucharis, Palms, and Ferns, while on the roof, in the healthiest luxuriance, hung fine specimens of Dendrobiums and Calanthes. The fourth division presented a fine appearance. Splendidly coloured Crotons and Dracænas lighted it up beautifully, and in addition the eye could rest on many very beautiful specimens of Palms, Ferns, and stove plants in general. Looking to the roof grand plants of Dendrobiums formosum giganteum, Wardianum, and noble were to be seen, also fine plants of Calanthes. The fifth division contains a mixed collection of Orchids, Vandas, Lælias, Cattleyas, Cœlogynes, and Dendrobiums being all represented by fine specimens in the best of health. Mr. Steel has a special liking for Dendrobiums, as natives of Burmah, where he has lived a considerable time. D. formosum giganteum is represented by numerous grand plants, one specially fine variety being in flower. The sixth division is filled with cool Orchids, mostly Odontoglossums, all in good health.

The third range of glass is, like the other two, 160 feet long. It is 16 feet wide by 13 feet high, and is span-roofed. It is in three divisions. The first is devoted to a general collection of greenhouse flowering plants, with Tomatoes trained up the rafters in front and over the whole of the back. Everything in this division seemed in the best possible condition. The second also contains greenhouse plants, mostly Pelargoniums, Celosias, Lilliums, Petunias, and Chrysanthemums. Habrothamnus, red and yellow, were planted on the back, also more Tomatoes. All these were, like the rest, in perfect health. The third division is planted with Peaches and Nectarines on the front and Figs on the back, the latter being nearly all Brown Turkey. The stage in this house was filled with a finely flowered collection of young Fuchsias, also Petunias, Vallotas, and early Chrysanthemums.

In front of this range a number of very useful pits are placed, 160 feet long by 6 feet wide; these were full of Cinerarias, Primulas, Capsicums, and French Beans. It is nearly always necessary to grow the latter in pits in such elevated parts of Selkirkshire, Philiphaugh being some 460 feet above sea level. It is only rarely that French Beans can be got to do well outside at Clovenfords, and the experience at Philiphaugh is much the same. In a sheltered corner in front of these pits 600 fine plants of the best varieties of Chrysanthemums were standing, all giving promise of being up to the mark when the time for blooming arrives. At a little distance from the main block of glass there is another fine range at the top of the new kitchen garden. It is 188 feet long by 10 feet 6 inches wide, lean-to. A considerable portion is planted with Peaches, back and front; the varieties being mostly Princess of Wales, Sea Eagle, and Late Admirable. There are also some Pineapple Nectarines. Another portion of the range is devoted to Plums, Pears, and Apples, all doing well.

Adjoining the young gardeners' quarters there is a span-roofed house, 40 feet long by 16 feet wide. At the time of my visit (Sept. 14th) this was full of fine Lilliums, Begonias, and Camellias, but in a short time it will be filled with Azaleas and such plants, which are at present outdoors. The Begonias and Lilliums were in fine bloom. I may mention the young gardeners' rooms, which are next to this house. They are new, and in every respect are what such quarters should be. Externally they are handsome, and internally they are commodious and comfortable. They are heated throughout with hot water, each man has a separate

bedroom, and there is a splendid bathroom. Mr. Steel deserves every credit for having provided such excellent accommodation for the garden assistants, and there are many places in the country where his example might well be followed.

The new kitchen garden is nearly 3 acres in extent, and the crops in it are very heavy. Evidently the soil is good, and aided by good culture. The fruit-rooms, store-rooms, potting sheds, and Mushroom houses form a fine range of buildings, and are, like all else about the place, excellent. The fruit-room being all in pitch pine looks a model of what such a place should be. The whole glass is heated by five improved saddle boilers with water bars. These are a great improvement, and are becoming much used.

The mansion is about four minutes' walk from the garden, and is a commodious and beautifully situated building. It commands a fine view of the hills and dales, the woods and streams that go to make the surrounding country beautiful. The conservatory, which is entered from the dining-room, and which is just being completed, is a handsome structure, 60 feet long by 42 feet wide, and 22 feet high. The framework is of iron, the only wood about it being the doors, which are of teak. The floor is most beautifully laid with octagons of different coloured marbles. There is a narrow bench round the sides for plants, beneath which there is a narrow pit for planting creepers in, and then in the body of the house there are two tanks to be filled with large Palms and Tree Ferns. Another space is to be occupied with a small fountain, and the rest of the house is for promenading and lounging in. Altogether it promises to be very beautiful when finished, and will enhance the pleasure of the proprietor without a doubt. Close to where the mansion stands was fought the battle of Philiphaugh. This memorable struggle took place between the forces of Charles I. and those of the Covenanters. It was fought on September 13th, 1645, and a monument in the grounds commemorates the event.

Should any of the staff or readers of the *Journal* ever happen to be in or near Selkirk they should not miss seeing Philiphaugh. Cultural skill, wealth properly directed, and natural advantages, all combine to make it one of the most interesting places in the country. Mr. R. Thompson, the able and energetic gardener, has shown what can be done in a short time to turn a bare field into a garden full of the choicest fruit, flowers, and vegetables. Since March, 1891, a new garden has been made, four large ranges of glass, a fine conservatory and numerous ranges of pits, also ranges of sheds, gardeners' house, &c., have been erected, roads, walks, and lawns have been formed—indeed, an amount of work has been done that speaks volumes for the directing skill and energy at command. Given another two years the place will be one of the most complete and interesting gardening establishments in the country. By that time the Vines will be showing what they can do under skilful treatment, and no doubt in due time some of their productions will adorn the show tables.

I may mention that the plans of the glass structures were prepared from sketches by my father. Philiphaugh is two and a half miles from Selkirk Station, whence there is a branch line to Galashiels, where the main or Waverley line is reached. Situated as it is amidst sylvan beauties, rich and rare, close to the murmuring stream of classic Yarrow and surrounded by the Heather hills, Philiphaugh has many charms. May its owner long enjoy its beauties. He has done much to encourage horticulture since he came to Selkirkshire, and his efforts, ably seconded by those of Mr. Thompson, are being crowned with conspicuous success.

—JOHN THOMSON, *Clovenfords*.

HORTICULTURAL SHOW.

CHELTENHAM.—SEPTEMBER 21ST AND 22ND.

THE annual Exhibition was held at the Winter Gardens as usual. It opened on the 21st in very unfavourable weather, rain falling in torrents most of the day, which considerably diminished the attendance. Taken altogether the Show was probably the best ever held, the exhibits generally being very good. For six stove or greenhouse plants Mr. J. Cypher was a good first, his *Statice profusa*, *Allamanda nobilis*, *Bougainvillea glabra*, *Erica Marnockiana*, *Clerodendron Balfourianum*, and *Ixora Williamsi*, all being fine. Messrs. Heath & Son staged well for the second prize, their best plants being *Ixora Duffii*, *Allamanda grandiflora*, and *Phoradendron prolifera* Barnesi. For a collection of thirty plants in or out of bloom, grouped for effect, Mr. J. Cypher put up some of his well known exhibition plants, consisting of well coloured Palms and Crotons, *Caryota sabilifera*, *Allamandas*, and others. Messrs. Heath and Son were a very good second with an effective group. With eight varieties of Fuchsias Messrs. Heath & Son were an easy first, having large well bloomed plants. Mrs. Gillilan, Cheltenham (gardener, Mr. A. Mansfield), was second. For six tuberous Begonias T. P. W. Butt, Esq., Arle Court, Cheltenham (gardener, Mr. Marsh), was first with good plants well bloomed, and Captain Littledale second. For eight varieties of Zonal Pelargoniums Mr. Lingwood, Cheltenham (gardener, Mr. Lewis), was first and Mrs. Gillilan second. With twelve exotic Ferns Mr. J. Cypher was a grand first. Messrs. Heath & Son were second.

Dahlias were of extra quality. Messrs. Heath & Son secured premier honours for twenty-four distinct varieties; Mr. G. Garraway, Bath, being second; and Mr. G. Maylett, Worcester, third. For twenty-four blooms of German Asters, Mr. A. A. Walters, Bath, was first; Messrs. J. Price & Son, Stonehouse, second; and Mr. F. Evry, Bath, third. With twenty-four French Asters, Mr. S. Cooper, Mr. G. Garraway, and Mr. T. Evry took the honours in the order named, all staging well.

For twelve varieties of Roses in bunches of three, S. P. Budd, Esq., of Bath, put up a beautiful lot and was placed first; Mr. J. Townsend being second; and Mr. T. Hobbs, Bristol, third. For the best dinner table decoration, Miss Sturt was a good first with a very tasteful arrangement, and Mrs. Gillilan, second, her exhibit being a little heavy. Gladioli were best shown by Messrs. G. & W. Yates, Evesham, J. Price & Son, and J. Cypher in the order named.

Fruit was extensively exhibited. White Grapes were not as a rule well finished. Apples, Pears, Plums, Peaches and Nectarines made a good display, and were very fine. In the collection of eight dishes of fruit, Lord Coventry (gardener, Mr. Child), Croome Court, Worcester, was a capital first with Muscat of Alexandria and Gros Colman Grapes, Queen Pine, Imperial Melon, Brown Turkey Figs, Humboldt Nectarine, Alexander Noblesse Peach, and Jefferson Plum, all fine. H. C. Moffat, Esq. (gardener, Mr. Spencer), Goodrich Court, Ross, was a good second with Alicante and Muscat of Alexandria Grapes, Queen Pine, Golden Gem Melon, Dr. Hogg Peaches, Pineapple Nectarines, and Souvenir du Congrès Pears. In the black and white Grape classes, Lord Sudeley, C. Lee Campbell, Esq., the Rev. G. Coventry, and T. P. W. Butt, Esq., were the principal winners. For Peaches and Nectarines, Colonel Rogers (gardener, Mr. Lusty) was the most successful exhibitor. With Plums, C. Lee Campbell, Esq., took the lead; Lord Coventry held the same position for Apples, and Mr. W. E. Smith for Pears.

Vegetables are always a strong feature at Cheltenham, but local men had to give place to Mr. Geo. Garaway, of Bristol, in the collection of nine dishes. He staged a model lot. Mr. A. Cook was second, also putting up a fine collection. For six varieties Mr. W. J. Davis, Stroud, was first, and Mr. J. R. Groatorex second, both exhibiting excellent produce. For Messrs. Sutton & Sons' special prizes the last named exhibitor was first, Col. Rogers second, and Mr. J. J. Kitchen, Birmingham, third. For Messrs. Webb & Sons' prizes Mr. G. Garaway was first, Mr. S. Evry second, and Mr. J. J. Kitchen third. The single dish classes were well contested, the above named being the most successful prizewinners.

Trade exhibits were very good. Mr. B. Ladhams, of Shirley, Southampton, put up a splendid collection of hardy herbaceous flowers; also Messrs. G. & W. Yates, who, in addition, had some fine Dahlias and Begonias on their stand. Messrs. White, of Worcester, had a fine group of Cactus Dahlias and other flowers.

HARDY FRUIT GARDEN.

Gathering Fruit.—Favourable weather having had a beneficial effect in rapidly maturing Apples, Pears, and Plums, frequent if not daily attention is required in examining the trees, carefully gathering the most forward fruits before birds or wasps select them for attack. It is important that those intended for storing be gathered in the most perfect condition. The slightest piercings with holes by birds or wasps render them quite unfit for prolonged storing. Many of the later varieties of Apples and Pears are still swelling well. These can be safely left to hang some time yet, taking the precaution, however, to gather them before very severe frosts occur. Slight spells will do no harm. Late Plums not yet gathered must be netted over or taken off the trees, storing in a dry fruit-room.

Lifting Fruit Trees.—This operation may be performed a little earlier in the autumn than root-pruning, though it effects a somewhat similar purpose. It is adopted chiefly with young trees which are portable and easily moved, but exhibit a tendency to produce strong gross wood; this, if allowed to remain unchecked at the feeding source, would destroy the balance of growth, leading trees into permanent unfruitfulness.

Advantages of Root Disturbance.—The best and most important roots of all trees of a fruit-bearing nature are those of a fibrous character. Such roots are produced by the occasional lifting and pruning back of the strongest roots, which are thus encouraged to emit fibres, and if these are supplied with good soil they ramify near the surface to the decided benefit of the trees. They multiply until a healthy mass of feeding fibres is secured, inducing firmer, shorter wood growth, and an abundance of fruitful parts. The first needing attention in this respect are the choicer stone fruits.

Peaches, Nectarines, and Apricots.—These being similar in growth and requiring almost identical treatment may, after a few years' growth, be lifted with advantage, providing they exhibit a gross tendency of wood growth requiring restraint. Lifting is best done in the early part of October before the leaves fall, though it may be done later. Take advantage of the opportunity to remove some of the inert soil, substituting fresh, consisting mainly of good loam mixed freely with wood ashes and one-fourth of lime rubble. In cold heavy soils drain the position thoroughly and replant on slightly raised mounds. Follow with a slight mulch of half-decayed manure to protect the raised roots from frost. The following year the effect will be seen in an even distribution of vigour and healthiness throughout. If bright weather should occur

immediately after lifting water at the roots will be needed, also syringing of the foliage and possibly shading.

Pears and Apples.—Lifting may be frequently done with these in the case of small or medium sized bushes as well as pyramids before the latter attain to full proportions. It is not advisable to lift wall-trained trees except in the case of Peaches, which are annually detached from the walls for the winter season. With these exceptions wall trees are better left permanently secured, invigorating the trees as needed with surface dressings and periodical root-prunings as required. Those in a fruiting condition will need no root disturbance.

Assisting Impoverished Trees.—Continuous crops of fruit being a great strain upon most fruit trees, especially in light soils, it is advisable to assist the roots when the appearance of the trees indicates any approach to weakness, or they are more than usually liable to attacks of red spider and other insects. There are two methods of enriching the ground in which the roots of old established trees are contained.

Applying Liquid Manure.—Where enough of this valuable fertiliser can be readily obtained there is nothing better for enriching the ground for fruit trees. Commencing now it may be frequently applied in open weather throughout the autumn and winter in moderate quantities at a time, distributing it over the whole area of ground bounded by the spread of the branches. Failing this, and in very dry soils, clear water would do good applied in sufficient quantity to moisten the ground well.

Surface Dressings.—When the ground is moist enough, though impoverished, remove some of the surface soil, and apply a dressing of loam and manure, charred refuse, leaf soil, or old hotbed manure. The roots this material comes in contact with will soon appropriate its virtues and increase in number, benefiting the trees considerably. After a time the advantages of treating trees liberally will be so apparent that in the future the process will be annually repeated.

Manuring Strawberries and Raspberries.—The ground between these being now quite clean and free from weeds, a moderately rich dressing of farmyard manure containing a fair quantity of short, strawy material may be spread between the plants. The warm autumn rains will wash down the virtues of the manure to the roots, which will become strengthened, increased in number, and charged with vigour for the next season's growth, while the strawy portion left on the surface as a residue serves to resist the action of severe frosts, and forms a very efficient protection to the mass of active fibres.

Young Strawberries.—Recently planted beds, after a final hoeing and drying of the surface to kill the seedling weeds, may have a thin protective covering of short littery manure spread between the plants, the object being to ward off cold cutting winds and prevent severe frosts crippling the foliage too much. The ground having been properly enriched at planting time needs little manurial assistance until near the cropping period.

Retarded Fruit.—Frequently examine Morello Cherries and Red Currants which have been matted or netted up to protect the fruit still hanging on the trees. If kept dry, moderately airy, and free from mouldiness, they will keep firm and fresh for a considerable time, but decaying berries allowed to remain for any length of time soon spoil the rest.

Renovating Neglected Fruit Trees.—If not previously done the first steps towards improving such trees as have had little or no attention for some time ought to be taken while the foliage is still present. Too much pruning is left, as a rule, for the winter season, because the importance of the thin disposal of wood during the period it is most needed—summer and autumn—is not sufficiently noted; hence the crowded state and unfruitful condition of many otherwise excellent trees.

Standard Trees.—These have frequently too many main branches, and are too often crowded in the interior with useless spray. Prune all the latter away close to the trunks or main branches from which it springs. Thin out the branches, especially in the centres of trees. Avoid shortening those left except where they may be encroaching on adjoining trees.

Wall and Pyramid Trees.—These, when large, have often an excess of branches with crowded clumps of spurs. Both should be well thinned out. Horizontally trained trees can, in many cases, have every other branch cut away with advantage. The same thorough removal can be also adopted with pyramids. Afterwards cut out crowded and ill-placed spurs, and shorten foreright shoots closely back. Trees of this description will require root-pruning to curb the excessive vigour they would otherwise exhibit next season.

FRUIT FORCING.

Melons.—In Houses.—As the days are shortening rapidly and the moisture increases it is necessary to exercise care and judgment in watering, never doing it unnecessarily, but the latest plants with fruit swelling must not be allowed to become so dry at the roots as to prejudice the foliage. Maintain moderate moisture by damping the floors, walls, and sides of the beds every morning and at closing time, and earth up the roots as required, but late plants require less soil to grow in than the midseason plants. Remove all superfluous growths as they appear, and maintain a temperature of 65° to 70° at night, 5° less on cold nights, 70° to 75° by day, up to 85° or 90° with sun. Keep the bottom heat at about 80°. Fruit ripening will be better for a little extra fire heat and a little air constantly; a dry condition at the roots, but not so as to cause the foliage to flag, accelerates the ripening process and enhances the quality.

In Pits and Frames.—In those heated by fermenting material no water will be required after this time unless the soil is dry and the foliage becomes limp, which it must not be allowed to do. Any water given must be so supplied as not to wet the foliage and surface of the bed more than can be helped. Keep the frames well lined, admitting a little air constantly, which, with the fruit raised well above the surface of the bed will do much to accelerate the ripening, prevent decay, and impart flavour. Any fruit it is wished to keep for a time should be cut when changing with a good portion of stem, and be kept in a dry airy room, or if wanted ripe at once it may be placed in a warm airy house on a shelf in the full sun. Melons ripen better there than in frames or pits devoid of artificial heat.

Cucumbers.—*Winter Fruiterers.*—These should be planted as soon as they are ready. A good bottom heat is essential to success, whether it be obtained by the aid of fermenting materials or hot-water pipes; but a somewhat higher temperature is needed to commence with if fermenting materials are used, as the heat will decline, and there should be hot-water pipes beneath to keep up the bottom heat when that of the fermenting material declines. The soil may consist of light turfy loam with a third of fibrous peat, a sixth of old mortar rubbish, and a tenth of charcoal, the whole well incorporated. It is better to rely on liquid manure and surface dressings than to employ manure in the compost for imparting vigour.

Autumn Fruiterers.—Strive to maintain a healthy and vigorous growth, and be careful not to overcrop the plants. Secure a temperature of 75°, say 65° at night, 70° to 75° by day artificially, and 80° to 90° from sun heat. Although a moist and genial atmosphere is essential a stagnant one should be avoided by careful ventilation, being particular not to admit cold and drying currents. Be sparing in the use of water, especially over the foliage, a genial atmosphere being secured by damping available surfaces in the morning and afternoon, but gradually reduce the moisture as the days shorten and the sun heat declines. Add a little fresh soil as the roots protrude at the sides of the hillocks or ridges, previously warmed, about every ten days or a fortnight; supply liquid manure once or twice a week, as may be necessary, and fumigate moderately on two or three consecutive evenings in case of an attack of aphides.

Plants in manure-heated frames or pits must have the linings renewed as required, the foliage being kept rather thin, the shoots well stopped to a joint beyond the show of fruit, and no more water given than to secure healthy moisture for the roots, placing mats over the lights on cold nights.

THE KITCHEN GARDEN.

Cauliflowers.—Since the introduction of the early dwarf varieties there has been less need to sow seed in the autumn and to winter the bulk of the plants thus raised under glass. It is not advisable, however, to wholly discard the old practice, and if a batch of plants have been raised in the open they should be taken good care of. Before they are very large the bulk of them should either be dibbled out in handlights on good ground, where some of them are to heart or be pricked out in frames set on a shallow bed of old heating material. The soil—any loamy mixture will do—should be raised well up to the glass, and after being made rather firm the young Cauliflowers may be dibbled out 4 inches apart each way. They will not move particularly well out of a bed of soil, and for this reason the plan of placing the plants either singly in 3-inch pots or in pairs in 4-inch pots finds favour with many, as the plants move out of these readily enough in the spring. In either case there must be no coddling, fire heat in particular being objectionable. All that is necessary is to protect from severe frosts and to ventilate very freely at all other times. It is now somewhat late to sow seeds, but if a frame and light or two newly cleared of Cucumber or Melon plants can be spared, level the bed, water if dry, and sow the seed thinly broadcast. Plants may be available next spring. Autumn-raised plants of Veitch's Autumn Giant will heart very early in the following August, this fact being turned to good account by the most successful exhibitors, and plants should also be raised in the autumn by those who are desirous of maintaining an unbroken supply of Cauliflowers.

Cabbage.—Those who sowed seed of Ellam's Dwarf Spring by the middle of July and other favourite varieties then or a fortnight later, should have, ere this, got out a good breadth of plants. According as the more weakly plants, and those raised later, become strong enough to move, find room for them, and failing a good supply of home-raised plants buy as many as are wanted from a reliable source, as it is scarcely possible to over-estimate the value of a good supply of spring Cabbages. They form a succession to either Onions or Peas, the ground not being dug in either instance. Strong growth is not desirable before the spring, and if the ground is somewhat poor now it can easily be enriched in March by means of liquid manure or surfacings of soot. Extra large Cabbages are the least economical. Instead, therefore, of placing the plants in rows 2 feet apart bring the stronger growers 6 inches nearer together, and those of the type of Ellam's Dwarf and Wheeler's Imperial may well be disposed 15 inches apart each way. If the first batch were put out 2 feet apart dibble plants of smaller growers midway between them and draw and use these first, the rest being left, if need be, all the rest of the year.

Beans.—In many low lying localities both Runner and Kidney Beans were destroyed by frosts on or about September 13th, this, in the case of the former, being before they had time to pay for the trouble taken with them. A few overhanging branches of fruit trees not

unfrequently afford sufficient protection from frosts, and in all cases where the Beans are injured it is advisable to have some kind of protective material, notably branches of Beech trees, in readiness for fixing over the rows. Cotton or canvas blinds, mats, and such like might be utilised for a similar purpose, and the Beans be kept in a productive state for another month. If dwarf Beans have been sown on a warm border with a view to protecting them they ought now to be well advanced in growth, and should be covered with frames or have benders and mats placed over them whenever the nights are cold. Those in pits and frames should be kept steadily growing, the aim being to have them in a productive state during November. Any sown at this comparatively late period had better be kept in pots and grown on shelves or light stages in forcing houses, much as they are forced in the spring.

Late Peas.—Late Peas also suffered badly from the frost alluded to, this being especially the case with those situated in the lower part of a garden. Those on the ridges between Celery trenches and on high ground generally were uninjured, and are producing serviceable dishes. If they could be protected much as advised in the case of Beans, gatherings might very probably be had up to the middle of November. Small birds are very troublesome among late Peas, completely marring many a good crop. They cannot be scared away, and nothing short of either trapping them extensively in the small bird gins supplied by most ironmongers, and baited with young Peas, or else of closely netting over the rows, will save the crops. Three-quarter-inch mesh netting is needed; failing it, use a double thickness of the netting that is available.

Endive.—Good well blanched Lettuce will soon be scarce, and Endive will be in demand accordingly. Supposing the more forward plants of the latter are nearly fully grown some of them should be blanched where they are growing. If the outer leaves are brought up well together and kept so by means of raffia ties, the hearts will soon blanch, though the process may be further expedited by means of 6-inch or larger pots inverted over them and the holes stopped. Endive planted out now will scarcely attain to a serviceable size before severe frosts set in, but small plants are usually the hardiest and may stand through the winter and give fairly good hearts next spring.

Spinach.—Where the ground was well prepared Spinach sown in August came up better than usual. It is the usual practice to thin out the plants as the thinnings become large enough to use, but this season it may have proved a somewhat risky plan. Nothing but free and early thinning out the ordinary round and prickly seeded varieties prevented them from running prematurely to seed, but the Victoria being naturally later and less given to bolting, fully maintained its credit. Should the weather keep mild even the later sowings must be early thinned out, the plants at first being left 3 inches apart, finally thinning them to about 6 inches. If grubs attack the plants they ought to be hunted for and destroyed, a pointed stick being the handiest thing for loosening the ground and bringing the grubs to light.

THE BEE-KEEPER.

APIARIAN NOTES.

HOME FROM THE HEATHER.

I HAVE returned home after nearly six weeks' stay at the Heather, the weather being almost sunless the whole time, accompanied with wind and a low temperature never before experienced by the oldest natives living. We had more sunshine on the 21st, the day I brought my bees home, than all the time I was there put together, and, singular to say, the only serene day since December, 1891. It is little wonder, then, that we envied the fine weather said to be prevailing in other parts of the kingdom, where large yields of honey have been obtained. We have unfavourable seasons frequently, but the present one at the Heather is the worst I have had for thirty years. The honey season on the whole is, however, better than it was in 1891 or in 1862 either. Taking memory and history into account, I find that we have had a succession of unfavourable summers periodically every thirty years: 1890, 1891, 1892; 1860, 1861, 1862; 1834, 1835, 1836.

MONOPOLY.

The greatest profit from honey goes into the dealer's pocket, much on the same principle as that from beef and mutton does. My pen did some service towards checking in the bud a system of honey dealing which, had it succeeded, would have bought all the honey in the country at 3d. per lb., and bee-keepers were to be thankful for that, as they had no right to expect remuneration for

time spent on bees. Had this succeeded there would have been an entire end to profitable bee-keeping, due entirely to so-called friends of bee-keepers. In addition to my remarks "A Hallamshire Bee-keeper" drafted at great labour a synopsis of a system for bee-keepers to dispose of bee products on a co-operative principle remunerative to bee-keepers. I mention this as introductory to other matters for the benefit of beginners, and I trust they will remember that all practical information on bees and bee-keeping was first promulgated through the *Journal of Horticulture and Cottage Gardener*. The best proof of this is to turn back a dozen years or so, and read on up to the present time the other journals both of this country and America. The question will naturally arise, Where did they get the information, and why have they changed their minds, and the management of bees? Turn to the pages of our *Journal* and the answer to the question will be clear.

WHAT VARIETY OF BEE IS BEST?

This is a question commonly put by beginners. Were I restricted to one pure variety, the Carniolan would be the selection. With them there is little or no stinging, consequently no veils or nauseous smoke are necessary, and the purest of sweets is got in all its purity. They are the best winterers of any, strong on the wing, long and distant flyers. They are industrious honey gatherers and quick sealers. They are of all the least inclined to rob other hives, but there are no bees entirely free from this vice. They do not, like some varieties, raise an enormous number of queens, and, as a rule, they are all perfect. When swarming, they sometimes fly a long time, but never to a great distance. They are the best locaters of their site, flying directly to it, and do not mix with other bees, as some varieties do. To prevent hiving after swarms, these, like all other varieties, should, on the ninth day after the first swarm, have all surplus queen cells removed, either by forming nuclei or to destroy them. Unfortunately pure Carniolans are not easily got now, the greater number having yellow bands characteristic of the Syrian bee, that bee being the one selected by dealers to cross others with on account of its beauty, and thus commanding a sale. I believe there is not such a bee as a pure Italian Alp bee in America, nor are Carniolans having yellow bands, or even those of a light colour, pure.

PURE CARNIOLANS

are easily known by their trig shape and light coloured markings, but the most distinguishing feature is when the wings are closed and the head of the bee towards you; owing to the reflected rays the anterior part of the abdomen appears to the deceived eye as reddish orange. Sometimes the bees of some colonies have a few brown hairs at the same point, but never anything like yellow bands. The crosses of the Carniolan are superior, and perhaps as good as any; but were I restricted to one cross only I would keep no other but pure Punic, crossed if possible with Carniolan drones. They possess all the properties sought by modern bee-keepers. The untoward seasons we have had since I became possessed of pure ones have prevented a fair test, but at the Heather a swarm of pure ones were a sight to see, rarely witnessed by—A LANARKSHIRE BEE-KEEPER.

TRADE CATALOGUES RECEIVED.

M. M. Ketten Frères, Luxembourg, France.—*Roses*.

Messrs. Ph. Mayfarth & Co., Frankfurt, and 16, Mincing Lane, London, E.C.—*Machinery for Horticultural Purposes and Fruit Evaporating*.

Messrs. W. Paul & Son, Waltham Cross.—*Roses, Hardy Trees, Shrubs, Herbaceous Plants, and Fruit Trees*.

Tottenham Nurseries, Limited, Dedemsvaart, Zwolle, Netherlands.—*Plants, Shrubs, Roses, Fruit Trees, &c. (wholesale)*.

Mr. Charles Turner, Royal Nurseries, Slough.—*Roses, Fruit Trees, and Nursery Stock*.

Mr. W. Wells, Earlswood, Surrey.—*Chrysanthemums*.

*All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Cypripedium (J. J. S.).—Please send a good flower packed in damp moss, so as to arrive in a fresh condition. That received was quite dried up, owing to spending Sunday in a box with nothing to keep it fresh, and we cannot form an opinion of it.

Peach and Nectarine for Unheated House (E. T. B.).—You could not have a better Peach than Royal George, and as a Nectarine none surpasses Victoria, but it is late, and if you want one to come in with the Peach you may select Dryden. We are not aware that the Violet named is in commerce; if it is it ought to be advertised.

Bulrushes Casting their Fluff (A Reader).—We are unable to tell you what will prevent the "flowers bursting;" but we have not found any difficulty from this after taking care to cut them with the necessary amount of stalk as soon as the pokers were just clear of the sheaths. That, it appears, you have not done, but have been too late. Perhaps some of our correspondents can assist "A Reader" to a preventive.

Wintering Fan Palms (B. C.).—If it be *Chamaerops Fortunei* it may be wintered safely in an outhouse or stable stall which has a fair amount of light, and the roots are protected with hay or straw, only giving sufficient water to keep the soil moist. Should it be a *Latania* it would not winter safely in such a position. The other is nearly hardy, and would succeed outdoors in sheltered positions, but it ought not to be put out at this time of year. Keep it until next spring in the outhouse, and then give it a trial.

Tea Roses for Growing in Pots (St. J. A.).—Of the varieties you name the following are suitable for growing in large pots, but it is a great mistake to overpot Tea Roses:—Madame Lambard, Madame de Watteville, William F. Bennett, Safrano, Marie Van Houtte, Souvenir d'un Ami, Comtesse de Nadaillac, and Hon. Edith Gifford. Maréchal Niel and Rêve d'Or are best planted out. We have not grown the others you name. Adam (President) and Madame de St. Joseph are excellent, as also are Sunset and the indispensable Niphetos.

Red Spider on Violets (Inquirer).—The best remedy is plenty of nutriment and copious supplies of water. We always mulch our Violet plants out of doors with manure as soon as they become established after planting, and we are never troubled with red spider either outdoors or in frames. Manure, keep the soil moist, and there will be little or no red spider. Put a peck of soot in a tub, use enough water to form a paste, then add 60 gallons of water, and with this syringe the Violet plants, using the clear liquid only. This will destroy the red spider and invigorate the plants.

Brompton Stocks and Wallflowers (W. D.).—The Stocks having been thrice transplanted ought to withstand an ordinary winter in sandy soil; still, as there is always the possibility of a severe winter occurring it is prudent to establish as many plants in pots as can be accommodated in a cold frame, or where some protection can be improvised. With a clear space between the rows of your Wallflowers the plants ought to be sufficiently hardy for passing the winter with little or no injury, but everything depends on the severity and continuance of frost. Tree leaves lightly placed amongst and over the plants afford good protection in severe weather.

Tortoise in Garden (A. B.).—We presume the "small tortoise" is the common European species (*Testudo graeca*), so frequently domesticated, and which occurs chiefly on the western borders of the Mediterranean Sea. The animal has the habit of hibernating through the colder part of the year, and retires to some quiet corner, from which it emerges in spring. We have no experience of it as a household pet, but it seems to require no feeding, usually finding sufficient insects about a garden and greenhouse to satisfy its appetite. It would be at home in a greenhouse during the winter, allowing it to retire, and taking care it is not disturbed. We find it has instinct enough to find out a snug place to hibernate. We have no experience of it outdoors, as it always takes care to get where it is comfortable when the cold weather comes on, and generally makes its "nest" in a greenhouse or similar structure.

Vine Leaves Deficient in Chlorophyll (R. H.).—The leaves you sent, though large, are thin, and the cells in the spaces between the veins are deficient in green colouring matter (chlorophyll), which causes the light appearance. This is probably due to overcropping and weakness, as the cell growth has exceeded the supply of nitrogenous matters necessary to the formation of the chlorophyll. A similar result is seen in the case of many etiolated or blanched plants that have been grown rapidly either in great heat or a dark position, the strength of the plants being exhausted in the cell-increase, and contain little besides water.

Forcing Spiræa japonica Two Years Consecutively (O. G.).—It is not desirable to pot the plants that were turned out after forcing, as they have not had time to recuperate. We divide our plants into two or more pieces with a spade when they have been sufficiently hardened off after being forced, and plant them in good rich light soil, in a sheltered, but not shaded nor hot and dry situation, in the garden, in rows 1 foot apart, and that distance between the plants, firming the soil well about the roots, and giving a good watering if the weather is dry. In winter they are mulched with spent hotbed manure or leaf soil, and, after growing the following summer, they are lifted and potted after the foliage has fallen, and they are plunged over the pots in ashes, and introduced to the forcing-house in batches as required. With a year's rest they make capital plants. If your plants are in pots we should plant them out now, let them grow next year, and lift and pot them in the following autumn. The plant is perfectly hardy.

Renovating a Vine Border (G. H.).—The best time to renovate a Vine border is when the leaves begin to turn yellow, but before they have fallen. The best compost is turfy loam taken off a pasture, about 2½ inches thick, where the soil is a good yellow loam, neither too light nor too heavy. Add to the turf a sixth part of old mortar rubbish and a tenth of charcoal, thoroughly incorporated. Thomson's manure is a good application, and may be mixed with the soil, but it is most economically given as a surface-dressing. Wood ashes and crushed bones may also be added to the soil with advantage, using about 2 cwt. of each to ten cartloads of soil. It is not wise to lift the roots in both inside and outside borders the same season, but to do one one year and another the next. The best time to lift Peach trees in an orchard house is when the growth is mature, and the leaves give indications of falling. Thomson's manure is a first-rate dressing for Peach trees if the instructions are followed. These subjects have received a large measure of attention in "Work for the Week" lately.

Striking Cuttings of Shrubs (Nemo).—Cryptomeria japonica is best propagated from seed sown in sandy soil in a pan, placed in a cool house, and covered with a square of glass until the seedlings appear; the glass should then be removed, the seedlings hardened and placed outdoors, wintering in a cold frame or house. Cuttings may be inserted now in sandy soil, surfaced with an inch of sand, under a handlight, preferably in a cold house. Biota cuttings should consist of half-ripened shoots, inserted about the middle of August in a cool shaded frame, or in pots put in heat and covered with a bellglass. Retinospora cuttings should be put in during October. Select young side shoots with a heel, insert in well-drained pots of sandy soil, place in a close cold frame, and keep just moist through the winter. By February they will be callused, and should then be placed in gentle heat; they will root freely, after which harden them off and plant them out. Cuttings of Aucuba japonica may be inserted now, though it would have been better done early in the month, in sandy soil in a cold frame. If taken off with a heel they will root in a sheltered situation without a covering of glass, but that is preferable.

Select Tea Roses for Outdoors (Tea Rose).—Tea Roses in the open air require protection in the winter, and when grown in beds it is advisable to take them up at the end of October, pot them, and keep them in a cold pit, taking care to have the lights off constantly in fine weather. They may be planted out again at the end of March or the beginning of April, according to the season. The soil should be rich, light, and well drained. They, however, do fairly well in a sheltered situation, with protection in severe weather, and a good mulching over the roots. Adam, Comte de Paris, Comtesse de Nadaillac, Etendard de Jeanne d'Arc, La Boule d'Or, Madame Bravy, Madame de St. Joseph, Princess of Wales, Souvenir d'Elise, Souvenir de Paul Neyron, Souvenir d'un Ami, Sunset, Viscountess Folkestone, Duchess of Connaught, and W. F. Bennett are moderate growers, and should be planted about 2½ feet apart, or 2 feet if on the margin of a bed. The following should be planted about 3 feet apart:—Beauté de l'Europe, Gloire de Dijon, Innocente Pirola, Belle Lyonnaise, Marie Van Hout e, The Bride, Reine Marie Henriette, Perle des Jardins, Lady Mary Fitzwilliam, and White Lady. It would be a good plan to have the ground well prepared, and defer the planting until spring, especially of those that are received in pots.

Names of Fruits.—*Notice.*—Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot

be preserved. (J. B.).—The dark Pear is Brown Beurré, the others Beurré d'Aremberg. (J. R. P.).—1, Cox's Orange Pippin; 2, Gloria Mundi; 3, Scarlet Nonpareil. (J. B. Dashwood).—Golden Noble. (Nemo).—3, Winter Hawthornden; 4, Reimette de Canada; 5, Ribston Pippin; the others not known. (Somerset).—Kerry Pippin. (J. Foster).—1, American Mother; 2, Blenheim Pippin; 3, Lord Suffield; 4, Emperor Alexander; 5, Cellini; 6, Emperor Alexander. (J. A. W.).—1 and 2 cannot be named, particulars of the flowers, whether small or large, not having been supplied; 3, White Magnum Bonum; 4, Washington; 5, Diamond; 6, Violette Hâtive. (Alfred Brook).—1, Nonesuch; 2, Bedfordshire Foundling; 3, Dumelow's Seedling; 4, Blenheim Pippin; 5, Duchess of Oldenburg; 6, not known. (A. W.).—1, Pearson's Plate; 2, Potts's Seedling; 3, Lord Suffield; 4, Manx Codlin; 5, King of the Pippins; 6, King of the Pippins. (J. R.).—1, Early Julyan; 2 and 3, We do not undertake to name inferior varieties (see above); 4, Warner's King; 5, Blenheim Pippin. (R. V. and Sons).—A very nice Apple, but do not know the name; probably Sugar-loaf Pippin. (J. B.).—Black Morocco. The Fig was quite rotten. (Faie).—B, Royal Russet. The others are probably continental varieties, as we cannot identify them with home-grown sorts.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (Bolney).—1, Helianthus decapetalus; 2, H. rigidus, large variety; 3, H. rigidus, small variety; 4, Verbascum phoeniceum album; 5, Aster Amellus; 6, A. novæ-belgii formosissimus; 7, A. n.-b. densus. (G. A. B.).—Lastrea varia. (F. A. B.).—The flower has puzzled several experienced men. It appears to be a Nerine; send us one or two more flowers in damp moss, and we will try again. (G. R. A.).—1, Griselinia littoralis; 2, Looks very much like Desfontainia spinosa, but the flowers were faded. (J. T. A.).—Veronica longifolia subsessilis. (Nemo).—1, Erodium manescavi; 2, Cotoneaster frigida. (E. H., Hull).—1, Pyrus intermedia; 2, P. Aria. P. Sorbus is the Service Tree.

COVENT GARDEN MARKET.—SEPTEMBER 28TH.

MARKET very flat indeed, with prices much depressed.

DAIRY FARMING.

THE series of reports just issued by the Board of Agriculture on dairying in Denmark, Sweden, and Germany contain many valuable hints and much useful information for British farmers. It is a disgrace to us that we have allowed Denmark and Sweden to wrest so large a share of our business from us. While we have been grumbling about hard times, and cherishing the blind conceit of a fanciful superiority, treating hints of the possibility of profitable change or improvement in farm management with contempt, they have been striving for improvement in everything and in every way. Have they succeeded? They have, but with all their success the one thing that still makes us hopeful of the future of dairy farming in this country is the fact of the best English or Irish butter being better than any we import. The importance of this is obvious; equally important is it also that first class home made factory butter is in such high demand that there is never enough of it. Managers of factories are outspoken enough about this, but they cannot help it, simply because there is a limit in the capacity of any factory to produce best butter. Milk must be delivered fresh to the factory to afford the best results, it suffers when sent from long distances; butter does not if it is carefully packed.

Plain and forcible is the teaching here. We have not applied it, but Munster farmers are doing so. With them co-operative factories are fast bringing about a revolution in farm management and farm profits. Only a short time ago the Irish lump butter which they sent to market reeking with filth, was practically profitless; now their factory butter competes successfully with any imported butter. The capacity of each factory is limited to the milk of eight hundred cows. Mark this, for it affords invaluable data for the guidance of English farmers. Not simply in the establishment of factories lies our chance of restored prosperity. If farmers are to derive all the benefit from them that is possible they must become shareholders, must have an interest in the whole of the concern, and not be mere suppliers of milk at so much per gallon. They have a splendid opportunity if they grasp it and retain the matter in their own hands. The price of milk will improve strictly according to its quality, but if they allow dealers to forestall them, and factories to become a trade speculation, then the price of milk will be forced down by competition of which the keen dealers will take full advantage.

But we may be told that farmers have no capital to float speculative butter factories. We hold that they possess ample means for doing so. The maximum amount required is £1 per cow, which is paid gradually by calls of 2s. or 3s. for buildings and plant. Once convince them that the scheme is sound and profitable and they will find the money fast enough. Many a farmer might advantageously take a hint from the life of a successful Cheshire farmer who began in a small country shop, then hired a small farm, taking six cows in valuation. Finding the farm did not afford sufficient food for that number of cows, he at once sold one of them, purchased corn and manure with the money, fed both cows and land better, and soon made twice as much cheese as his predecessor had done. Ways and means are plentiful, the great want generally is intelligence to use them. We waste our strength in trying to do too much, we go beyond the scope of our means, are altogether too diffuse. Concentration and centralisation should have much more attention than has hitherto been accorded them by farmers. Their concession to the centralism of the day is to send farm produce to large centres of population. That is right so far as it goes, but

it is for them to see that their produce goes to market in the right form. Because it answers to send milk to London from Essex, Kent, or Surrey, it by no means follows that it can be sent profitably from farms outside the radius of the home counties. It would be better for all southern and midland farmers if the metropolitan milk supply were confined, say, to a radius of twenty miles; then if outside that radius other centres were formed by the establishment of co-operative butter or cheese factories requiring all the milk from surrounding farms, the price of milk would be higher, all factory shareholders at least would have a wholesome incentive to breed or select cows for both quality and quantity of milk. There would then be a general improvement in dairy cows, profits would be higher, farmers would not be so much at the mercy of foreign competitors, and the chief industry of the country would be more prosperous, and less liable to periodical depression. All this calls for organisation and business capacity. We hope next week to show how much of the success of Swede and Dane is owing to this.

WORK ON THE HOME FARM.

Wheat has been harvested so well that threshing machines are in constant use, notwithstanding the low prices. The farmer has now something to sell for which he is paid at once; he is short of ready money, so he sells—it can hardly be said at a profit. The best sorts of Wheat for seed are in demand in the market, a good sample of well-known sorts meeting with a brisk sale at a few shillings per quarter above market price. In most districts there are now some growers of seed corn who find it answer fairly well to purchase a certain quantity of seed from the great seed firms, to raise a stock of seed for sale. If they are thus able to place a good sample of seed on the market it goes very well, because they sell at a comparatively low price; but competition is now so keen that an inferior sample has no chance.

Sow a good sample of winter corn, and sow thickly; thin seeding and bare fallows have had their day. Thick seeding for a full crop and to smother weeds is now answering. No corn hoeing, no bare fallows, and a thick plant of corn all tend to keep down expense. A pound or two per acre saved in crop production, another pound or two gained by having more produce to sell, just make the difference between success and failure. Sow no corn on poor or inferior soil, manure well, and be satisfied with nothing less than a full crop. If there is a doubt about having enough green food in spring, do not hesitate to sow more Rye; it will come into use quickly after the first sowings, and will serve admirably to keep the flock going. Near large towns all green fodder answers well for sale. It may either be sold on the land or sent direct to consumers. The latter plan is preferable, because the work may just as well be done by the farm men, and the carts can always load back with manure. Peat moss and sawdust from town stables are both excellent fertilisers; saturated as they are with urine and containing a large admixture of horse dung they are useful both as top dressings and for ploughing-in. Nothing answers better for fruit plantations and Strawberries as a top dressing. Have a sufficient quantity of either or of short farmyard manure at hand by November for top-dressing fruit trees and bushes as they are planted. Never forget that all our best farmers—the successful men—invariably keep the soil well stored with fertility, for only by doing this is it possible to have full crops.

REMARKS.

- 18th.—Sunshine throughout.
 19th.—Bright sunshine almost throughout.
 20th.—Heavy shower at 6.45 A.M., then alternate cloud and bright sunshine; generally overcast afternoon.
 21st.—Overcast and gloomy early; heavy rain from 9.30 to 10.30 A.M., and occasional showers after; some sunshine at midday, and thunder about 3.30 P.M.
 22nd.—Overcast with occasional drizzle.
 23rd.—Occasional sunshine, but generally cloudy.
 24th.—Overcast, with frequent slight rain early; sunny after 11.30 A.M.
 A generally fair autumn week, with temperature rather above the average.—G. J. SYMONS.

ROSE ANALYSIS, 1886-92.

THE Crystal Palace Exhibition of the National Rose Society proved this year the most extensive the Society has yet held. On the other hand, the number of Roses tabulated for the purpose of this analysis is the smallest for six years. This apparent anomaly is, however, easily accounted for by the fact that at all previous Exhibitions four prizes in nearly all classes have been awarded, whereas this year there were but three prizes in each class. Consequently, as this analysis only concerns itself with those flowers which appear in prize stands the number at our disposal is considerably smaller than it otherwise would have been.

The following statement gives the number of Roses noted down at each of the last seven Exhibitions, making a total of 13,000 Rose blooms in all.

	1886	1887	1888	1889	1890	1891	1892
Hybrid Perpetuals ...	1038	1130	1247	1176	1396	1184	1121
Teas and Noisettes ...	509	642	854	778	631	662	554
	1547	1772	2101	1954	2027	1846	1675

Owing to the early date (July 2nd) at which the Society's Metropolitan Show was this year held, and the season being again a backward one, the late flowering varieties are once more placed at a certain disadvantage in the analysis. The influence of the seasons has not, I find, so serious an effect on the relative positions occupied by the different varieties as might be supposed. No doubt the reason of this is that unless the summer prove exceptionally backward there are sure to be certain districts where even the later flowering Roses are in bloom on the day of "the National," and it is of course from these favoured spots in the south of England that on such occasions a large number of the blooms in the prize stands invariably come. Nevertheless, in order to obtain strictly comparable results it is very desirable that the early and late summers should be as equally balanced as possible.

The established varieties among the Hybrid Perpetuals which were more frequently shown this year than at any of the six previous Exhibitions were La France, Charles Lefebvre, Etienne Levet, Duke of Wellington, Le Havre, and Victor Hugo. Madame G. Luizet, A. K. Williams, Marquise de Castellane, Baroness Rothschild (one of the latest flowering of all the H.P.'s), Dupuy Jamain, Heinrich Schultheis, Fisher Holmes, and Comte Raimbaud were also considerably above the average. On the contrary, Marie Baumann, François Michelin, Captain Christy, Alfred Colomb, Marie Verdier, Comtesse d'Oxford, Xavier Olibo, Beauty of Waltham, Madame V. Verdier, and Marie Cointet were all very indifferently represented. Marie Baumann, usually regarded as the most certain exhibition flower of all the H.P.'s, was this year staged less frequently than at any of the six preceding Shows.

Although there are about seventy varieties on the list of Hybrid Perpetuals only four of them are less than six years old—viz., Mrs. J. Laing, Earl of Dufferin, Jeannie Dickson, and Gustave Piganeau. Of these Mrs. John Laing, which was sent out in 1887, takes a very high position, already standing at No. 3 in the analysis. Last year it was also at No. 3, but its claim to that position only rested on its record for a single show, whereas now it has been made dependent, and I think more correctly, upon the average

number of times it appeared in prize stands at the last three exhibitions. This year it was staged oftener than any other Rose whatever in the Show. It is light pink in colour, and if that light pink were only somewhat clearer in tint and its petals smoother at the edges than they generally come, it would be as nearly as possible a perfect H.P.; indeed, there are few varieties, old or new, possessing as many good qualities. Earl of Dufferin is another 1887 Rose, and, like Mrs. J. Laing, was also raised in the British Isles. This deep crimson variety has but slightly improved on its last year's position, rising only from No. 38 to No. 35. But then it must be remembered that it comes into flower rather late in the season, and consequently has been placed at a disadvantage the last two years. Gustave Piganeau, No. 46, introduced in 1889 and making its first appearance on the list this year, promises to be a high class exhibition Rose. On maiden plants it has proved itself very dependable, and should it turn out to be a sufficiently strong grower on cutbacks, which at present appears doubtful, it is likely at no distant date to rise to one of the leading positions in the analysis. Jeannie Dickson, No. 42, was first distributed in 1890, and, like Earl of Dufferin, was raised by Messrs. A. Dickson & Sons of Belfast. The flower is a very distinct shade of rose pink, and considering the short time this variety has been out has been well shown. It may be mentioned in passing that the same firm this year received the gold medal of the National Rose Society at Chester for a charming Rose of a very similar colour, entitled Mrs. W. J. Grant, which, judging from the blooms then exhibited, may be best described as an improved Jeannie Dickson. It will be interesting to watch the progress of this promising new Rose in future issues of our analysis. It may, however, be a year or two before we see Mrs. W. J. Grant again, as the stock of it is stated to have been purchased by an American.

The Teas, which at the last Exhibition distinguished themselves by appearing in more prize stands than at any other show of the series, were Souvenir d'Elise Vardon, Madame de Watteville, Madame Cusin, and Princess of Wales. Innocente Pirola, Maréchal Niel, Hon. Edith Gifford, and Anna Ollivier were also exceptionally well shown. As regards Maréchal Niel we have to go back to the 1887 Exhibition in order to find so many blooms of this variety at a National Show; in fact, this year there were only two other Teas or Noisettes as numerous shown. On the other hand, Souvenir d'un Ami and Madame Lambard were never before so poorly represented, while Marie Van Houtte and Jean Ducher were also very scantily exhibited.

Our list of Tea and Noisette Roses is gradually being extended, five fine varieties having been added to it during the last few years. First comes The Bride, a nearly white sport from Catherine Mermet, which we received from America in 1885, and which since last year has risen from No. 5 to No. 3 in the analysis, being bracketed with Comtesse de Nadaillac. This year it was staged more frequently than any other Tea Rose in the Show. It may here be mentioned that there is another sport from Catherine Mermet little grown at present, but which will no doubt before long also secure a good position on the list, and that is a deep pink one called Waban, also an importation from America. Madame Hoste (No. 26), distributed in 1887, is a lemon-yellow variety. For some reason it has scarcely improved on its last year's form, but nevertheless is such a good Rose that it is pretty certain sooner or later to take a higher place. To the year 1888 we are indebted for a remarkably fine new Tea, I need scarcely say that I refer to Ernest Metz. It is salmon rose in colour, and appears in the analysis for the first time at No. 21. The long-budded pale pink Cleopatra, sent out in 1889, rises from No. 31 in last year's list to No. 17 in the present one, and was surprisingly well shown at the last Exhibition. Souvenir de S. A. Prince, a white sport from Souvenir d'un Ami, like the variety from which it originated, was less frequently to be seen this year than at any previous show. Nevertheless it is a Rose which has wonderfully

improved in constitution during the last two years, and is sure to become a great favourite.

In days gone by nearly all our good Roses came to us from France, but a glance down the columns in the two tables giving the raisers' names and dates of introduction of the different varieties will at once show how few high class Roses we have

received from the Continent in recent years. During the twenty years ending 1881 the French raisers sent us no fewer than fifty-seven out of the Roses mentioned in the analysis, or on the average nearly three choice varieties a year. In the same period only twelve Roses sufficiently good to find places in the analysis were sent out by our own nurserymen, and among these there was not

HYBRID PERPETUALS.

Position in Present Analysis.	Average Number of Times Shown in the Seven Years.	Number of Times Shown in 1892.	Name.	Date of Introduction.	Raiser's or Introducer's Name.	Colour.

32	11.9	10	Duke of Teck	1880	Paul & Son	Crimson scarlet
32	11.9	16	Fisher Holmes	1865	E. Verdier	Shaded crimson scarlet
33	11.6	8	Abel Carrière	1875	E. Verdier	Crimson maroon
35	11.3	8	Earl of Dufferin	1887	A. Dickson & Son	Deep crimson
35	11.3	10	Prince Camille de Rohan	1861	E. Verdier	Crimson maroon
36	11.0	6	Pride of Waltham	1881	W. Paul & Son	Light salmon pink
37	10.9	9	Monsieur Noman	1866	Guillot	Pale rosy pink
38	10.2	4	Madame Victor Verdier	1863	E. Verdier	Clear light crimson
39	9.7	5	Violette Bouyer	1881	Lacharme	Tinted white
40	9.6	11	Viscountess Folkestone	1886	Bennett	Creamy white, shaded pink
41	9.3	7	Duchess of Bedford	1879	Postans	Light scarlet crimson
41	9.3	7	Sénateur Vaisse	1859	Guillot	Bright crimson
41	9.3	7	Star of Waltham	1875	W. Paul & Son	Carmine violet
42	9.0	9	Jeannie Dickson	1890	A. Dickson & Son	Bright rosy pink
43	8.8	9	Countess of Rosebery	1879	Postans	Carmine rose
44	8.7	8	Marguerite de St. Amand	1864	Sansal	Clear rosy flesh
45	8.3	3	Marie Cointet	1872	Guillot	Light pink
46	8.0	8	Gustave Piganeau	1889	Pernet & Ducher	Carmine lake
47	7.8	11	Victor Hugo	1884	Schwartz	Bright crimson, shaded
48	7.7	7	Charles Darwin	1879	Laxton	Brownish crimson
49	7.5	9	Comte Raimbaud	1867	Rolland	Clear crimson
49	7.5	3	Reynolds Holc	1873	Paul & Son	Deep scarlet maroon
50	7.0	2	Duchesse de Morny	1863	E. Verdier	Silvery rose
50	7.0	5	Madame Eugène Verdier	1878	E. Verdier	Light silvery rose
51	6.7	11	Suzanne M. Rodocanachi	1883	Lévêque	Bright silvery rose
52	6.5	8	Madame Isaac Perèire (B)	1880	Margottin, fils	Carmine red
53	6.2	3	Auguste Rigotard	1871	Schwartz	Cherry red
54	6.1	4	Madame H. Jamain	1871	Jamain	Pale flesh
55	5.9	4	Magna Charta	1876	W. Paul & Son	Bright pink carmine
56	5.8	3	Queen of Queens	1883	W. Paul & Son	Pale blush pink
57	5.3	7	Victor Verdier	1859	Lacharme	Clear cherry rose
58	5.1	9	Dr. Sewell	1879	Turner	Violet crimson
59	5.0	5	Mrs. Baker	1876	Turner	Bright cherry rose

a single Tea. Now, if we compare this record with a similar one for the last ten years the contrast will be seen to be very great. Of the nineteen varieties which bear a later date than 1881 only seven were received from France, thus giving an average of less than one Rose a year. Of these seven French Roses three are Hybrid Perpetuals:—Merveille de Lyon (1882), Suzanne Marie Rodocanachi (1883), and Gustave Piganeau (1889), while four are Teas—Hon. Edith Gifford (1882), Madame de Watteville (1883), Madame Hoste (1887), and Ernest Metz (1888). Moreover, all the four Teas were sent out by the same raiser, Guillot. Of the remaining twelve varieties, nine were raised in England, two in Ireland, and one in America, eight of them being H.P.'s, and four Teas—viz., 1882, Princess of Wales, Lady Mary Fitzwilliam, and Heinrich Schultheis; 1883, Queen of Queens; 1885, Her Majesty and The Bride; 1886, Viscountess Folkestone; 1887, Mrs. John Laing and Earl of Dufferin; 1889, Cleopatra and Souvenir de S. A. Prince; 1890, Jeannie Dickson.

To those kind friends who assisted me in taking down the names of the Roses in the prize stands at the last Exhibition my thanks are again due.

It is not every exhibition Rose that can be recommended for ordinary garden cultivation, but the following may be depended upon as likely to grow and flower well in most localities. No time should now be lost in ordering the plants from the nurseries. They will then arrive in November, when they should be at once planted,

as it is very important to get them in the ground as early as possible. Plant firmly, and it is a wise precaution to at once secure each plant to a firm stake.

HYBRID PERPETUALS.—*Light coloured varieties.*—Madame Gabriel Luizet, La France, Mrs. John Laing, Merveille de Lyon, Captain Christy, Marie Finger, Baroness Rothschild, Viscountess Folkestone, Grace Darling, Jeannie Dickson, and Augustine Guinnoiseau. *Medium Reds.*—Ulrich Brunner, François Michelin, Marquise de Castellane, Comtesse d'Oxford, Marie Verdier, Dupuy Jamain, Heinrich Schultheis, and Camille Bernardin. *Reds.*—A. K. Williams, Marie Baumann, Alfred Colomb, Duke of Edinburgh, Ferdinand de Lesseps, Dr. Andry, E. Y. Teas, Sénateur Vaisse, Victor Hugo, Earl of Pembroke. *Dark varieties.*—Charles Lefebvre, Louis Van Houtte, Prince Arthur, Duke of Wellington, Prince Camille de Rohan, Duke of Connaught, and Sir Rowland Hill.

TEAS AND NOISETTES.—Innocente Pirola, Souvenir d'un Ami, Marie Van Houtte, Caroline Kuster (N.), Honourable Edith Gifford, Francisca Krüger, Anna Ollivier, Madame Lambard, Rubens, Souvenir de S. A. Prince, Madame Hoste, Souvenir de Thérèse Levet, Jules Finger, Ernest Metz, William Allen Richardson (N), and L'Idéal (N.). The two last named are not exhibition Roses, but should be in every collection however small.

BOURBON.—Souvenir de la Malmaison, and Mrs. Paul.—E. M. Berkhamsted.

TEAS OR NOISETTES.

Position in Present Analysis.	Average Number of Times Shown in the Seven Years.	Number of Times Shown in 1892.	Name.	Date of Introduction.	Raiser's or Introducer's Name.	Colour.

HOW TO IMPROVE OLD VINES.

VINES possess such marvellous recuperative powers that it is somewhat difficult to determine when they are worn out. After they have reached an apparently worthless stage it is surprising how quickly they may be brought back to health, vigour, and fruitfulness again. I do not advocate the renovation of old Vines in preference to planting young ones in cases where the loss of a crop for one or two seasons is of no material consequence, and when labour and expense are matters of secondary consideration, provided they lead to the production of superior Grapes. There are, however, numerous instances in which Vines are in a very

unsatisfactory state. This ought not to be allowed to continue without some effort being made to improve them. With proper treatment vast improvement may be effected in one season without the loss of a crop, and when once they are brought back to a healthy state old Vines may be depended upon to produce good crops of Grapes annually so long as they are well cared for; in fact, it is no unusual occurrence to find old Vines under the charge of a good cultivator bearing Grapes immensely superior to those produced on young Vines by less skilful growers.

There is no better time than the present for taking in hand the renovation of a Vine border in which early forced Vines are growing. The laterals will have been shortened back to five or

six leaves in order to plump up the remaining buds. The few leaves retained will not be seriously affected by the necessary disturbance of the roots, and will, moreover, when the work is completed, help to incite root action before falling. I have on many occasions had to deal with Vines after they have been completely or partially lifted, and from their subsequent behaviour have learnt many useful lessons. The result of my experience leads me to advise all who contemplate the overhauling of Vine borders, especially those in which early Vines are growing, not to attempt too much the first year, or the intended remedy may prove worse than the evil. If the roots are partly in an inside and partly in an outside border, the ordeal of lifting is sometimes not so trying for the Vines, because they are chiefly supported by the roots in the undisturbed border till young ones are formed in the fresh soil. Unfortunately, however, it is seldom that both borders are well furnished with roots, which generally confine themselves almost entirely to one or the other. Be content, therefore, with lifting those in the outside borders the first season.

The first thing to be done is to shade the roof of the vinery with mats or canvas; next dig a hole near one corner of the border right down to the drainage to ascertain the condition of it. In nine cases out of ten, if the border was well made, this will be in good working order, although the soil above may be close and sticky. This state of affairs is caused by too deep a border, by the use of too much animal or vegetable matter in its composition, and by the absence of a sufficient quantity of such porous and sweetening materials as lime rubble, charcoal, or bones. The roots found in a border which has lapsed into this condition are invariably long and destitute of fibre. To take out the whole body of soil down to the drainage, and then force the Vines the same season, would be to court failure; in fact, I have seen many old Vines ruined by resorting to such extreme measures, and I have had charge of other Vines which have been greatly improved by partial lifting, although they were forced hard enough the same season to produce ripe Grapes the first week in May.

The practice I advocate is partial lifting. Carefully remove the soil with a fork to the depth of 12 or 18 inches. This is best done by taking out a trench at the extremity of the border opposite the vinery. As the work proceeds all roots found should be preserved uninjured as much as possible, and be tied to stakes driven into the border. This will keep them out of the way of the operator as the soil is forked out from among them and wheeled away. Moreover, it enables the roots to be kept moist and fresh by giving an occasional syringing, and keeping them covered with mats. In all probability the majority of the roots found will be deficient in healthy fibre, the principal ones being deep down in the soil beneath. Having proceeded thus far, next mark off from 5 to 6 feet from the front wall of the vinery and drive a strong stake into the border at each end, then loosen the surface of the soil with a fork the whole length of the border, keeping the same width as the stakes indicate. When the forking is completed give a good dressing of soot, and place on it a layer of lime rubbish an inch or so in depth. A layer of prepared soil should be spread upon this, and if dry be trodden firmly. Spread about half the roots evenly over this surface, cutting notches with a sharp knife at intervals of 6 inches to induce them to send out fibrous roots at those points. Another layer of soil should next be placed over these roots.

As the work proceeds a wall of turf, with the grassy side placed downwards, should be built up to form a continuous straight line between the two stakes at each end of the border. A trench must next be cut along the entire length of the border, at the boundary; this ought to be opened down to the drainage, cutting off all roots which are met with. If the border has not been confined within brick walls, the probability is that many strong roots will have extended beyond the border, the severance of which will cause a considerable check to the Vines. In such cases it is not wise to disturb the roots any further at present. They should, however, be for the future confined to the border by building a wall along the trench already formed or by filling it up with concrete. All that remains to be done in the present case is to remove a little more soil from the lower level of the border—between the turf wall and the outer one—till roots are found, when a few inches of fresh soil should be added, and the whole surface of the border covered with 6 inches of half-decayed leaves. If when taking out the trench along the front of the border few, if any, roots are found, the soil may be removed quite up to the strip of border already completed, and marked off by stakes, the roots found as the work proceeds being, of course, carefully preserved. The drainage should then be cleared, and if found defective re-arranged. Use some freshly broken bricks and old mortar rubbish to finish off with, taking care to cover this with brushwood, bracken, or straw before fresh soil is added. The

roots should then be spread out in layers in the fresh soil, taking care to keep the bulk of them within 3 inches of the surface.

When completed the border will be in two sections, the one nearest the house being 12 or 18 inches higher than the other containing the surface roots, which previously extended the entire width of the border, while those roots in the outer half of the border which were deep down in the soil are brought within the quickening influence of fresh air and sunshine without being subjected to the trying ordeal of complete lifting, which in many cases would be disastrous to early forced Vines. If the Vines are allowed to make plenty of growth during the growing season after a couple of years the section of border nearest the house will be filled with healthy fibrous roots, for in addition to the roots sent out from the notched portions of the old roots another set will spring from the main stem of the Vines. These will perform the best future work, and should therefore be encouraged by filling up the lower section of the border with fresh soil, through which the young surface roots will steadily permeate, and if these are kept active and healthy by top-dressing and good treatment Grapes of high quality will be the result.

Vines in later houses may be completely lifted with more prospect of success, but even in their case better results may often be obtained by working on the lines above indicated. Of course in all cases the work of lifting should not be begun till after the Grapes are cut, and if the foliage is still on the Vines shading and syringing must be resorted to to keep the leaves fresh as long as possible. A good compost to use for the purpose is one consisting of six loads of good turfy loam, one of horse droppings, one of burnt refuse, half a load of lime rubble, 1 cwt. of half-inch bones and 3 bushels of soot, the whole to be thoroughly mixed before using.—H. DUNKIN.

THE PROTECTION OF PLANTS.

VARIOUS means are employed by Nature for the dissemination of plants over the surface of the earth and for their preservation. The natural forces, water, wind, animals, and even man are the most active agents of this dissemination, and many interesting species have been introduced into certain countries by their influence. If some plants appear in places where they had never been seen before there are others on the contrary which disappear from a locality, a country, or entire continent. Without discussing the subject of the great changes made in the flora of a country in the course of time I wish to call attention to certain plants, the approaching disappearance of which is anticipated and lamented by botanists, and at the same time I shall explain the measures taken in certain countries to protect those species which are most in danger.

Some will no doubt smile when I talk about protection. "Nature," it will perhaps be said, "does not require your intervention; it maintains itself, and we have only to preserve the greatest neutrality with regard to its works." This is true; but the neutrality must be absolute, that is to say it must be respected by all. From the instant of its being violated by some who strip the earth of its most beautiful ornament it is a duty to adopt measures for placing a check on these depredations. Certain kinds of animals formerly abundant, like the bison of America, the whale, the elephant, and lion, are rapidly decreasing, and they will probably disappear entirely. Some plants are menaced with a similar fate.

Psadia rotundifolia was at one time very abundant in the island of St. Helena, and in spite of its inelegant form it is of special interest, as it belongs to the great family of Compositæ, most known representatives of which are herbaceous plants. Here we have a tree of 6 to 7 yards in height with heavy naked branches bearing small Aster-like flowers. Man and goats have played such havoc with it that the numerous forests which covered the island have vanished, and this vegetable species would now be reduced to this single individual were it not for the fact that some have been planted and cultivated at Kew. One of the most graceful species of *Eucalyptus*, *E. alpina*, formerly abundant on Mount Williams in Australia, would now be unknown had not Baron Von Mueller of Melbourne planted a specimen in the Botanical Gardens. It is gradually being propagated by seeds and in other ways.

It will perhaps be said that this suppression of certain trees is an exception. True, it is rarely that man, in spite of his activity, is able to destroy or annihilate a species of plant. But we know the effects produced by the systematic clearing of woods. What has become of those immense forests which formerly covered Germany so thickly that a squirrel could travel from Strasbourg to Königsberg leaping from branch to branch? It is but three years ago, says a traveller, that it rained every day at Para; the vegetation was of extraordinary luxuriance. Since the population

of Brazil has increased the virgin forests have been cut down or burnt, and the cool shades have given place to a sterile and barren desert. Now months pass without a drop of rain falling. In France, on the Alps of Dauphiné, we find the slopes dry and arid; the rock appears everywhere. The environs of Gap lost their life with their forests. Have the Swiss anything more precious than the Arole (*Pinus cembra*, L.), the most majestic of forest trees, and which grows on the highest slopes? This species formerly existed in large forests; at the present day only some remnants are to be found.

A terrible consequence of this clearing, this stripping of mountain slopes, is the frequency of inundations. Forests exercise a salutary influence from the point of view of meteorology. At the time of heavy rains not only do the tops of the trees play the rôle of umbrellas, but the soil of the forest acts like a sponge, absorbing the water, and allowing it to run away gradually without endangering the lower parts. In the countries where the timber has been cleared away, on the contrary, the waters at once become formidable. At the Universal Exhibition, in the Forest Pavilion, the schemes presented for the turning of torrents comprise at the same time the replanting of the slopes at the foot of which the waters roll.

When I speak about the protection of plants I mean the humble flowers of our woods just as much as the large trees which shelter them under their branches. The savant is interested in not letting any vegetable species disappear; for him the loss of a species is equivalent to the disappearance of an interesting page of history. Clearings, works of public utility, the extension of the culture of useful plants, the draining of marshes cause changes in the local flora sometimes of a marked description, destroying rare plants, and causing the disappearance, in some localities, of interesting species. For the single department of Somme, M. Gonse recently called attention in the "Bulletin de la Société Linnéenne du Nord de la France" to the fact that some fifty species had disappeared or were tending to disappear. The species of plants most menaced are those which are sought by amateurs or horticulturists on account of their gracefulness, the brightness of their flowers, or merely their rarity. Let us add to these spoilers some botanists who do not even respect the rarest plants, and are in the habit of sacking everything wherever they pass.

The dwarf Palm *Chamærops humilis*, L., the only one of its family a native of Europe, was formerly in the environs of Nice. In 1841 M. Cosson, directed by M. Risso, a Nice botanist, gathered leaves on the last stalk, nothing but leaves, which have been preserved in his herbarium. This plant, which had been spared by all the inclemencies of the weather, which even resisted the effects in 1820 of a nocturnal cold ever memorable for the south of France (10° C.), and which killed in one night all the Orange trees of the Mediterranean coast, was destroyed by the Vandalism of foreign botanists, who extirpated even the last representative of the Palm.

Spiranthes Romanzoviana is a very interesting plant. Its white flower exhales an exquisite perfume. Its only station known in Europe is a small meadow on the borders of Bantry Bay, in the south of Ireland. After numerous visits from botanists, the complete disappearance of this Orchid has recently been remarked. —V. BRANDICOURT, *Librarian of the Société Linnéenne of the North of France.*

(To be continued.)

ODONTOGLOSSUM GRANDE.

THIS magnificent cool house Orchid usually flowers during October and November, and the brightness of its colouring enlivens the collection at a dull period of the year and commands attention. The pseudo-bulbs are distinct from other *Odontogloss*s, being ovoid, 3 inches long, and of a peculiar green colour. They are surmounted by a pair of broad leaves, 4 inches long, striated. The scapes are produced from the base of the bulb, and bear three to six flowers, each about 6 inches across. The sepals are oblong-lanceolate, yellow, with bars and blotches of reddish brown; petals oblong, broader than the sepals, lower half reddish brown edged with yellow, upper half bright yellow; lip roundish, very pale yellow, with a few red spots and blotches. The flowers last in perfection from three to four weeks. *Od. grande* was discovered in Guatemala in 1839, and flowered in England for the first time in the Duke of Bedford's collection at Woburn in 1840 ("Bot. Mag.,"

t. 3955). Although it may be grown and flowered in the cool house, yet this *Odontoglossum* requires a drier and slightly warmer temperature during its resting period; after growth has ceased hardly any water will be needed until it commences again. No collection should be without this, the finest and certainly the most showy species of the genus.—C. K.

PERISTERIA LINDENI.

PERISTERIA LINDENI (see fig. 41) is a new species introduced a few months ago by L'Horticulture Internationale, Parc Leopold,

FIG. 41.—PERISTERIA LINDENI.

Brussels, and which flowered in spring at their establishment. It is distinguished by a new and very attractive colour. The flowers, which are globular in form, are abundantly spotted and washed with dull purple on a clear greenish yellow ground. They are produced to the number of five to seven on an erect stem, which rises very little above the bulbs. This new species, when exhibited at the April meeting of L'Orchidéeenne at Brussels, obtained a diplôme d'honneur of the first class unanimously. It forms plate 328 of *Lindenia*.—MAX GARNIER (in "Le Journal des Orchidées").

CŒLOGYNE OCELLATA.

INTRODUCED in 1822 from Sylhet by Mr. Loddiges, this charming Orchid holds its own as an intermediate or cool house plant. Although usually flowering early in the spring it often produces blooms about this time of the year. Grown in baskets or pans and suspended near the glass in the intermediate house or the warmest end of a cool structure it succeeds, and when flowering looks exceedingly pretty. The pseudo-bulbs are ovate, purplish and wrinkled, surmounted by two leaves each about 6 inches long, deep green and leathery. The erect racemes are produced on short peduncles from the apex of the bulbs and carry from three to six flowers. The flowers are starry in appearance; the sepals and petals are pure white, spreading, oblong; the lip is joined to the column and is three-lobed; the side lobes are erect and obtuse, the central one elongated, white tinged with yellow and veined with orange and brown. At the base of the middle lobe and on the inside of the lateral ones are several large orange spots; three raised wavy lines

run longitudinally down the centre of the lip. The column is white tipped with yellow.—C. K.

CYPRIPEDIUM HARRISIANUM.

THIS fine old plant is now flowering in various Orchid collections, and is a great favourite because of its strong constitution and its free blooming quality, the flowers when cut lasting a considerable time in water. *C. Harrisianum* is interesting as being the first hybrid "Lady Slipper" ever produced by artificial cross fertilisation. It was raised by Mr. Dominy at Messrs. J. Veitch & Sons' nursery at Chelsea in 1864 and flowered for the first time about five years later; it is a hybrid between *C. villosum* and *C. barbatum*. The leaves, which are about 8 or 10 inches long, are blotched with dark and pale green. The dorsal sepal is deep purple with a white margin, black veinings, lower sepal green; petals, upper halves (horizontally) purplish brown with dark veins, lower halves greenish yellow; the lip is dull, purplish, with greenish front. *C. Harrisianum* requires ordinary care; it grows and flowers freely, and succeeds either in an intermediate or stove temperature.—C. K.

CYPRIPEDIUM SAUNDERSIANUM.

THIS, one of the rarest and most distinct hybrid *Cypripediums*, is now in flower at Mr. William Bull's establishment. It is the plant purchased of Mr. Lee of Leatherhead for 300 guineas, the price conveying in some measure an idea of its choice and remarkable character.

DENDROBIUM PHALÆNOPSIS.

THIS Orchid is not only the best of the Australian *Dendrobies*, but it is one of the very best of the several hundred species known.

For its cultivation it requires the hottest and moistest stove, and it grows best when placed in a position close to the roof-glass. Messrs. Sander & Co. recommend for it the treatment of the Pine stove, or such as suits *Crotons* and *Ixoras*. The Kew plants are grown in baskets, and are planted in peat fibre and sphagnum. They are liberally watered and syringed when in growth, and are kept moderately dry after the growth is matured. It may be stated in proof of the good nature of this *Dendrobium* under cultivation that the plant sent to Kew by Mr. Forbes ten years ago is still in good health, and has flowered this year.—W. WATSON (in "Garden and Forest").

DISCUSSION ON APPLES.

HOLLANDBURY.

I SEND a sample of Apples for your inspection picked from a tree in a grass orchard about a fortnight ago, the tree bearing a heavy crop. Two years ago I gathered an Apple from the same tree weighing 17 ozs. It is a good cooker, and the tree is a good grower. The fruit keeps until November. I should like to hear if you know of any varieties similar to it, and shall look in the *Journal* for any remarks you may publish relating to so excellent an Apple.—F. WOOLLARD.

[The Apples received appear to be very fine specimens of the Hollandbury, known also as Kirk's Scarlet Admirable, Hallingbury, Horsley Pippin, and Hawberry Pippin. It is described in the *Fruit Manual* as very large, skin deep yellow tinged with green on the shaded side, but bright deep scarlet where exposed to the sun, generally extending over the whole surface. A beautiful and showy Apple for culinary purposes; in use from October to Christmas. To that description Dr. Hogg adds the following note:—

"I have not been able to trace the history of this handsome Apple beyond the close of last century. It is not mentioned in the copious list of Miller & Sweet, of Bristol, in 1790, nor in any of the nursery workings of the Brompton Park Nursery, lists of which are in my possession as far back as 1750. The first record of it I find is in the Forsyth MSS., where, under the name of Kirk's Scarlet Admirable, he seems to have received it in 1799, and again in 1801, from Ronalds, of Brentford, as Hallingbury, but in his *Treatise on Fruit Trees* it is called Hollingbury."

The Hollandbury makes an excellent orchard standard, and also succeeds well on the Paradise stock.]

NOTES FROM NEWBURY.

I WAS pleased to see Mr. Bunyard's notes on Lady Sudeley, as I have several trees of it that at present have failed to bear fruit, although planted under the same conditions as other varieties that have fruited several seasons. There is little doubt, as your correspondent states, that some varieties have a partiality for a particular soil. With me the old Keswick is one of the best early Apples, but Lord Suffield will not thrive either as a standard or dwarf, being subject to canker. Our best crop of kitchen Apples this

season are Keswick, Ecklinville, Small's Admirable, Winter Hawthornden, Striped Beefing, and Lane's Prince Albert. Dessert.—Worcester Pearmain, King of Pippins, and Blenheim Pippin, which generally does well in this district. Some young trees of Scarlet Nonpareil and Baumann's Red Reinette also have good crops of well coloured fruit.—J. HOWARD, *Benham*.

KESWICK CODLIN.

I HAVE on various occasions mentioned this variety in notes on the fruit crop as being a sure cropper, and therefore well worthy of extended culture. During the past twenty-one years an espalier-trained tree of Keswick Codlin has annually borne a full crop of good fruit. Our soil is a light loam of an average depth of 2 feet, and rests on a gravelly subsoil.—H. W. W.

WORCESTER PEARMAIN.

THIS very handsome, highly coloured, and good quality dessert Apple is not met with in gardens so often as it undoubtedly deserves to be. I believe this excellent variety, like Keswick Codlin, does best in a somewhat light soil resting on a substratum of gravel. An espalier of Worcester Pearmain bore a fine crop of fruit here this year, which, owing to their handsome conical shape and beautiful colour, commanded the admiration of all who saw them; so much so, indeed, that I was loth to gather them, and therefore allowed the fruit to drop into the net with which it was necessary to protect them from the ravages of the birds.—W. H. W.

DOMINO.

WHEN on a large Kentish fruit farm towards the end of July I was much struck with the splendid appearance of a quarter of Domino. Standards planted five years ago were carrying 2½ to 3 bushels of fine fruit, which, sold at 6s. per bushel, would be 15s. to 18s. per tree. Considering, however, that even as early as Cherry gathering times quantities of good size fruit could be picked, this price would in all probability be exceeded. The fruit is borne in heavy clusters, and the thinnings gathered early and sold at a remunerative price would tend to the better development of the general crop. I particularly call attention to the value of this excellent Apple for planting in exposed positions. There are few high-class culinary varieties that will retain perfect health and fruitfulness under such trying conditions as Domino. Its tendency to come into early and profitable bearing on the free stock points to the fact that it would be valuable on the Paradise, where a hardy variety is wanted. I have also seen it in Nottinghamshire, where it is grown somewhat extensively, and its character for hardiness, sturdy growth and fruitfulness, is similar to that which it is earning in Kent. This is worth bearing in mind.—W. P. W.

STIRLING CASTLE.

IF I were asked to name one cooking Apple for a small garden I do not see how I could ignore the several good points which this variety possesses. As far as I know it only has one fault—bearing too freely—so much so that but little growth is made. Fortunately, however, the remedy is in our own hands—severely thinning the fruit. In the early part of November, 1890, I planted several trees of this sort, one especially in the kitchen garden. No particular pains were taken with it, beyond selecting a suitable day and carefully mulching the surface with some light half-decayed manure. Last year the tree carried nine handsome fruits, and this season the total weight of fruit borne is 14½ lbs., everyone a model in itself as to form, colour, and clearness of skin. Not a sign of speck or rust is apparent in one of the forty-two Apples borne. The tree has made growths 1 foot long, which is rather good for this variety. The colour of the leaves is a dense green; indeed the tree is the picture of health in spite of the heavy crop of fruit allowed to mature. Amateurs would do well to plant this Apple where space is limited. No sort that I know requires less attention in pruning and summer pinching of the shoots, the heavy crop of fruit invariably borne does all that is necessary in this direction. It is reported that when the trees are worked upon the Paradise stock they do not live many years, but quickly exhaust themselves. Be this as it may, when excellent trees can be bought for 2s. each it matters little. The outlay is quickly recouped.—E. M.

PRUNING APPLE TREES.

It was formerly a hard and fast rule not to commence the pruning of hardy fruit trees until after the leaves had fallen, but now it is considered to be the right thing to prune early, sometimes before the fruit is gathered. Why wait until the leaves have fallen, I would ask, when the work can be done so much more comfortably and with so much greater judgment before that period? It is much easier to judge which branches require removal or to determine where there is sufficient space for additional shoots to be

left from the current year's growth, when the leaves are still on the trees. October is a good time to prune the trees; indeed, I have already gone over many of ours. The main point to impress upon beginners in pruning is the absolute necessity of providing abundance of light and air between the branches; overcrowding them is the commonest cause of non-success. In high and moderately dry districts I am of opinion that much more regular crops of Apples would be annually produced if greater attention were paid to keeping the branches thinner than at present, and to following a regular system of summer pinching of the shoots. By this means the branches and buds in the embryo state are more matured and the flowers in a better condition to become fertilised, also to withstand light frosts. By following this method of pruning and summer pinching closely many of our trees have given us a full crop of fruit for the last ten years without fail. I am an absolute believer in the extension method of training Apple trees, of course where space will permit, as against the practice of close pruning of the branches and shortening of the roots with a view to the restriction of the trees generally. For this reason I regard a loose form of bush tree as being infinitely better than a formally trained pyramid tree, both from its giving more and better fruit and as requiring less attention in the matter of labour in training.

In pruning trees that were planted one or two years ago some attention must be paid to the manner in which they were pruned the same season as they were planted, as this will guide the future manipulation of the branches. I am a staunch supporter of pruning the trees the same season that they are planted, although I know that some persons prefer to let them alone for a year and then cut them back. I think this is a waste of a season, when equal growth can be had the first season by pruning the trees judiciously—i.e., cutting the shoots made the previous year to within about six eyes of the base, varying a little according to the manner of growth of each variety, some sorts being longer jointed than others. The second year I prune to within, say, 1 foot of the previous cut; sometimes more is left if plenty of space is available for the tree. By shortening the shoots back in this manner well-formed trees are obtained right from the base. It is an advantage to take the point out of any shoot over 9 inches long when dealing with trees planted less than five years; such shoots are thus induced to break more regularly into growth from all the eyes than when left untopped, the flow of sap is diverted from the leader, and if all the shoots are not required (as they will not be) fruit spurs may be encouraged to form by pinching the young growths during summer. Very often vigorous shoots will fail to send out side growths at all if left intact, all the sap flying to the point of the shoot and thus leaving it quite bare of spurs or side growths. This is neither desirable nor necessary considering that topping the shoot at the autumn pruning would obviate the defect. Timely attention to these apparently small details in pruning will render young trees not only a pleasure to look upon but a greater source of profit through the increased production of fruit.

In dealing with, say, two-year-planted standard trees, which were cut hard in the first season and are now furnished with shoots 2 feet long, or in some cases more, half of the shoot—for instance, the growth made last year—will now be bristling with fruit buds of this season's formation for next year. I do not advise these shoots to be interfered with at all if the last year's growth gives promise of forming buds and shoots, but if there is not sufficient evidence for the future furnishing of the tree I advise the point of the shoots to be taken out as directed. Next season these trees will bear fruit if allowed to do so, and if the weather at blossoming time is favourable, and the weight of the fruit on the long and, in some cases, upright shoots will induce the branches to form shapely heads by bending down the points of each. It is a mistake to crowd the branches of standard trees at any time, and especially the first two or three years. Each shoot should be allowed sufficient space to stand alone with a view to its maturity and the due formation of the future tree.

In pruning bush trees that have been established fully ten years I do not hold with the hard cutting-in of the points of the leading shoots if they are strong and inclined to make vigorous growth, and space is available for extension. I prefer to allow them to extend, simply removing the point to hasten bud and side shoot formation. After a couple of years of this treatment the length of the leading shoots will be considerably lessened, fruitfulness of otherwise bare branches will follow, and the necessity for root-pruning will diminish, providing, of course, that the roots are in a healthy condition and near to the surface. Especially does this method of pruning agree with Cox's Orange Pippin, Blenheim Orange, Warner's King, Ecklinville, and Mère de Ménage, all of which, with the exception of Blenheim, can be relied upon for an annual full crop of fruit. Abundance of space should be provided for the branches by a free removal of the current year's shoots, first by summer pinching to about three or four eyes, then cutting back

at the present time to one or two, so that a free admission of light and air to the inside of the tree is insured at all times.—E. MOLYNEUX.

A WOMAN'S CHOICE.

DURING the course of a conversation on Apples recently the wife of a nurseryman and fruit grower mentioned the advice she had given to her husband for extending his plantations. It was to this effect:—"Plant as many trees as you like, but the three sorts that always bear and are always good are Keswick Codlin, Ecklinville, and Alfriston. Those are the Apples for me, and I can do very well without any others." This is not a very bad choice. Who can name three more useful varieties?—A GARDENER.

DOCTORS DIFFERING.

THE notes given in the last number on different sorts of Apples seem likely to be useful, but "doctors differ" apparently on a most valuable point for those intending to plant—viz., what varieties will be best suited to their soils. Mr. Brotherston says Lord Suffield does not succeed on a light soil, while Mr. Bunyard, whose authority is second to none, says in his catalogue that it "does best on a light loamy or stony soil," and, I may add, that is a fair description of my land, and it does well with me. Again, the former says, "Cellini and Stirling Castle for heavy soils only," while Mr. Bunyard says of Cellini, "should not be planted in cold soils." I was thinking of trying Cellini, and should be inclined to trust Mr. Bunyard. Keswick Codlin does not do well with me, being poor in growth and in fruit, and Wellington, though growing well, gives me small samples. Lord Grosvenor is very good, and Alfriston and New Hawthornden give me nice crops of good Apples. Reinette de Canada has never failed to give me a crop of handsome and useful fruit. Lane's Prince Albert crops well, but I expect it likes a better soil, as the fruit is not very large, but even then the wood is so weak that it requires support. Of that excellent dessert Apple, American Mother, I have this year the best crop and the finest samples that my tree has ever borne. We had only a fair show of bloom, but the flowering season was so fine and favourable, without any frost, that I was much disappointed at the very small proportion of blossoms which set. It looked like being a bad year for Apples, but they have stayed on and filled out well, and in my own garden, and generally in this part of Suffolk, we have quite an average crop.—W. R. RAILLEM.

THE MARGUERITE CARNATIONS.

IN last week's *Journal of Horticulture* you inserted a short paragraph written by me in reference to some hybridised seedlings which are now in flower at the Spark Hill Nurseries, Birmingham. They are a marvellous improvement on the Marguerites, and show clearly that a great future is before this new race of Carnations when our practical florists take them in hand. They are also exciting attention, as may be seen by brief notices in the gardening periodicals, and in one or two instances inquiries made as to their origin. They were introduced from Germany, and in a catalogue now before me from a leading seed-grower there, are to be found under the heading of *Dianthus*, as *D. caryophyllus nanus fl.-pl.* *Margueritæ* (the new dwarf double Margaret Carnation). The plant is thus described: "An excellent annual Carnation, height about 18 to 22 inches. Sown early in the spring the plants will flower from July until winter, which renders this new Carnation very valuable for cut flowers as well as for market plants, and the play of colours consists of from fifteen to twenty various shades."

This description conveys a good idea of their qualities and habits, but I could not look upon them with much favour except as attractive border plants, because of their very serrated edges and want of form and texture or stoutness in the flowers. But it became a question of how far any improvement could be effected by crossing with our fine exhibition flowers, and Mr. C. H. Herbert, who is rapidly rising to the front as a cultivator and exhibitor of Carnations and Picotees, determined to try what could be done in this way. He crossed a Marguerite with pollen from Robert Houlgrave, scarlet bizarre Carnation, a prize variety, very rich in colour and of the finest form. This was done last September, for the Marguerites did not flower until the greater portion of the prize flowers were out of bloom; however, a late bloom or two of Robert Houlgrave enabled an experiment to be tried and a pod of seed ripened. The seeds were sown in February last, the seedlings pricked off and grown into handsome young plants, which are now flowering, and are the *beau idéal* of what pot plants should be for indoor decoration. They are in 48-pots, are from 18 to 20 inches high, well-formed bushy plants with from twelve to twenty blooms and buds on each, and with stronger and better foliage than the Marguerites. The latter possess a good erect

habit of growth, keeping the flowers well up, and especially so in the greatly improved seedlings now flowering at the Sparkhill Nurseries. The improvement in form, size, and substance is very remarkable, viewed as the result of a first cross between the two distinct sections. I sent you petals of the scarlet, and it is a very fine variety, with an almost smooth edge, fit for any stand of self blooms, and the plant is a picture of beauty. Another is a scarlet flaked or rather striped flower, for it is not distinctly flaked, as in our prize varieties. It also shows greatly improved form and size with great breadth of petal, but has a very serrated edge. Another is a good maroon purple self, and another a purple striped variety. All are double, and a great advance in every way as improved Marguerites. Mr. Herbert is again crossing these varieties, and will save every flower for seed, but as all our exhibition varieties are now out of bloom, and so many flowers of the seedlings have yet to open, further crossing will not be easy except from these seedlings.

I unhesitatingly say that there is a great future before this new section, for in reality they are to be regarded as annuals in this way—seed can be sown in January or February, and the seedlings grown so as to be strong flowering plants in the autumn. All other Carnations, including the very pretty free blooming bright scarlet double Grenadin, have to be treated as biennials—that is, the seed sown one year and bloomed the next; but with the Marguerite section, about seven months is sufficient to have strong flowering plants from the seed sowing. They should not be kept in warmth at any time, but treated in a hardy manner. No doubt the idea of improvements by crossing has occurred to others. I have not heard of others' experience. Next year at our Carnation shows, if the new race of seedlings can be got into bloom in time, Mr. Herbert will be able to show what he is doing, and if not then in flower other opportunities will crop up for their being seen.

The Marguerites, Grenadins, and the very beautiful double and single varieties of the Heddewigi and laciniatus families of Dianthus are all so richly deserving of the attention of amateurs that I very strongly recommend their culture, but to be grown in a hardy way. The two latter sections should be planted as single plants and not in clusters, so that their full beauty may be seen. Seeds are easily obtainable.—WILLIAM DEAN.

FUNCTIONS OF VINE LEAVES.

MR. W. IGGULDEN, in his latest contribution to this subject, page 286, has failed to bring forward any weighty arguments in support of his theories for two reasons. One is, that he tries, by citing exceptional cases to prove his previous assertions; the other, that he shows how in careless hands only the practice he condemns may prove a "snare and a delusion." It is seldom indeed that a careless cultivator achieves good results, less often great ones, and never lasting cultural successes. Let us, therefore, leave out the case of the careless cultivator, and argue on the assumption that whatever system is pursued it is intelligently carried out.

Mr. Iggulden is not, I am sure, the man to contend that Vine leaves badly infested with red spider are otherwise than injurious to the health of a Vine at whatever stage of growth they are allowed to establish themselves. The fact that he has been able to produce well-coloured Grapes and a thriving colony of this abhorred insect on the same shoot was probably because the colouring process was almost completed before the red spider was allowed to rest undisturbed. Then, again, it depends in a great measure upon the size of the bunch as to whether one or four primary leaves were necessary to secure perfect colour. Supposing, for the sake of argument, the bunch having four leaves beyond it was smaller than that having only one, the greater number of leaves may not have been necessary to effect the colouring of that particular bunch; they would, however, add materially to the health and vigour of the Vine, and by helping to maintain a vigorous circulation enable the one primary leaf to elaborate a greater quantity of sap than it could do if all the shoots had been stopped at one joint beyond the bunch. It is easy enough to obtain large bunches and berries for a few years by close stopping, but deterioration soon begins. Small and medium sized bunches colour well enough with but little growth beyond them as long as there is plenty of good leaves on other parts of the Vine, but I have never seen a large bunch satisfactory if treated in the same way. If Mr. Iggulden succeeds in colouring the bunch of Gros Colman he speaks of as perfectly as he usually colours that variety his theory will gain credence to a certain extent; but too much reliance ought not to be placed upon solitary instances; he must first prove it to be the rule before we can accept it as a conclusive proof.

Then with regard to the undoubted fact that bunches left on a

leading growth often produce small berries. This, Mr. Iggulden admits, is an extreme case, but that it first set him thinking on the subject. I am afraid, however, his active brain did not allow him to think quite deep enough to take into consideration how little analogy there generally is between the treatment a leader and a lateral receives. No doubt it is possible to be too liberal in allowing primary leaves beyond the bunch, especially if the shoots are allowed to go unchecked from the start to finish, as is often the case with a leader, extending sometimes to 6 or 7 feet beyond the bunch. Compare this treatment with that which the laterals receive, even when these go unstopped till they have made four leaves beyond the bunch. They are ready for that operation by the time the berries commence swelling, and sub-laterals do not make any great amount of growth till the stoning process begins; the fruit would then begin to be benefited by the elaborated sap, the leaves up to this time not being sufficiently solidified to perform the work of elaboration. In the case of a leader, however, the growth would be going on just at the time when the sap might, with advantage, be forced into the bunches. Some cultivators pursue the excellent practice of stopping their leaders when they have made about 3 feet of growth; the lateral, which shows at the point, is then rubbed out. This causes the main bud to break strongly and grow freely. Under this treatment I, and no doubt Mr. Iggulden as well, have seen grand bunches with fine berries brought to perfection, notwithstanding the fact that many feet of growth existed beyond the bunch.

The Muscat Vine rods in the famous vinery I referred to, were, as far as I can remember, about 6 feet apart, and the black varieties a foot or more less, but I maintain that by growing them at the distances apart I have previously stated would not result in a less weight of crop per superficial foot of glass, for the extra space given to each Vine enables it to perfect a corresponding increase of crop. With plenty of foliage and active roots one Vine will carry with ease a crop which to another would be ruin. I am inclined to think that the majority of cultivators consider active roots and the necessity for frequent applications of water a most satisfactory state of affairs rather than otherwise; to me it is a sure indication that all is well. Mr. Iggulden, somewhat ingloriously, tries to bring in the case of another famous vinery, the Vines in which he describes as having "gone wrong," although treated on exactly the same lines as I have advocated. He does not go so far as to say they have done so in consequence of having been so treated, but he leaves readers to infer as much. I can readily comprehend to what vinery he refers, but I have recently heard, from to a most reliable source, that the partial failure is attributed quite a different cause. This I was assured to be the case by an individual whose ideas on Vine culture are thoroughly well known to Mr. Iggulden.

I am fully convinced that numbers of Vines which get into a weak and unsatisfactory state do so to a great extent because they are persistently closely stopped, and I am equally certain that hundreds of others may and are greatly improved by allowing greater freedom of growth, in conjunction with good culture in other respects. Under the close stopping system Vines may be at their best when six or seven years old. There are, however, many Vines which are better at twenty than at six years old. I will even go so far as to say that Mr. Iggulden's Vines have been greatly benefited by the practice he now condemns. His strong advocacy of close stopping has only recently been adopted, and I think in his own practice only partially carried out. When I saw the Vines under his charge I found, unless my memory plays me false, young rods being taken up from some of them, and the principal rods by no means closely disposed; so that, although his Vines are old, they are still satisfactory, because a good deal of extra growth has been annually going on, and even this year he has shown that some laterals have been allowed to develop five leaves beyond the bunch. I fully believe that if he continues for any length of time the close stopping he now advocates he will, sooner or later, find it wise to abandon the practice.—H. DUNKIN.

I do not wish to intrude myself into the discussion between Mr. Iggulden and Mr. Dunkin, at its present stage at any rate, but I do think the former might profitably expound his views on the two closing lines of his last paragraph, page 286. "The colouring will be satisfactory enough, but something else besides good leaves is responsible for that." This "something else" many persons would, I think, like to know. Mr. William Taylor once said in the pages of this Journal that he could undertake to colour any Grapes (I am not, however, certain now whether he did not allude especially to Black Hamburgs, but I am writing from memory), if the Vines were not overcropped and the roots were active. For years I wished I knew Mr. Taylor's secret. I have no idea on what principles he worked, but for several years now I have

had no difficulty in colouring Grapes provided the Vines are fairly healthy and the foliage good and free from insect pests.

All that is needed, in addition to adequate support, to colour Grapes well is abundance of air day and night during the colouring period. The majority of badly coloured Grapes is not alone due to overcropping, or the foliage devoured by red spider, but by growing the Vines in too close, too moist, and too confined an atmosphere. Such treatment is detrimental to the colouring of Grapes. I have found Grapes to colour best when the structure in which they are grown is ventilated from the time they commence colouring as liberally as a greenhouse. Early in the season a check is avoided by gradually subjecting the Vines to cooler and more airy treatment. If this liberal ventilating principle were carried out more generally we should hear less of scalding in the case of Lady Downe's and other late kinds.

I remember once saying there was no more difficulty in scalding Black Hamburgh and Madresfield Court than in scalding Lady Downe's. The statement met with a good deal of opposition at the time. As I stated then, I can state now in good faith, that scalding is not constitutional to Lady Downe's, but is brought about by the cultivator, and can by him be prevented. — WM. BARDNEY.

ROSES AT THE PRINCIPALITY NURSERY, DEGANWY, LLANDUDNO.

ON paying a recent visit to the above—the latest addition to Messrs. Wm. Clibran & Son's nursery grounds—I was agreeably surprised to observe such a transformation scene in so short a time, rough uncultivated grass land having been quickly changed to a breadth of Roses. The nursery is about 15 acres in extent, and is mainly devoted to Rose-growing, for which purpose the marly loamy soil is eminently suited, as evidenced by the clean and healthy appearance of the 30,000 or 40,000 plants grown. There was not a weakly plant to be seen, nor was any mildew or rust to be observed on the place. All classes were making strong, sturdy, useful growth with every prospect of splendid well-ripened plants for sending out in November. It has been unnecessary as yet to use manure of any kind, and as long as the natural soil will produce similar blooms, and such strong and sturdy, but not gross plants, none will be needed. In the pure air of their breezy hillside the blooms of H.P.'s develop wonderful depth of colour, and the exquisite and delicate shades of the Teas and Noisettes come out to perfection.

All, or nearly all, the plants are grown as dwarfs, the stock most extensively used being the Briar in both its cutting and seedling form, and the results so far have proved the wisdom of the selection. Hybrid Perpetuals, as a matter of course, are largely grown. Of varieties of recent introduction, the white La France, Augustine Guinoisseau, and Sir Rowland Hill are conspicuous, and they are very effective in contrast. Among the older varieties the following are particularly noticeable:—Alfred Colomb, A. K. Williams, Baroness Rothschild, Duchess of Bedford, Duke of Edinburgh, Merveille de Lyon, Annie Wood, Captain Christy, Chas. Lefebvre, Comtesse de Serenye, Général Jacqueminot, Her Majesty, La France, Lord Macaulay, Louis Van Houtte, Madame Gabriel Luizet, Marie Baumann, Monsieur E. Y. Teas, Mrs. J. Laing, Mrs. Jowitt, Prince Arthur, Prince Camille de Rohan, Reynolds Hole, Rosieriste Jacobs, Sénateur Vaisse, Sultan of Zanzibar, and Ulrich Brunner. The Teas are pictures of health and vigour. They are grown in immense quantities, and where all are so good it is almost invidious to make comparisons; still some are found to merit a special note. Climbing Niphetos is in grand condition, and there is no doubt of its climbing propensities as grown there. Mrs. James Wilson is also strongly in evidence, and likely to prove a fine acquisition, and so is White Perle. Of Anna Ollivier, Catherine Mermet, Innocente Pirola, Madame Cusin, Marie Van Houtte, Souvenir d'Elise Vardon, The Bride, Rubens, Souvenir d'un Ami, Princess of Wales, Perle des Jardins, Niphetos, Madame Lambard, Madame de Watteville, Devoniensis, and Climbing Devoniensis, I can say no more than that they are seen at their best. Among the Hybrid Teas Grace Darling and Lady Mary Fitzwilliam are conspicuous even in good company, and so are Maréchal Niel and W. A. Richardson among the Noisettes. Bourbons also receive their quota of space and careful attention. In this class Kronprinzessin Victoria and Mrs. Paul struck me as being a pair of grand autumnals.

Space will not admit of copious notes, so that many of the varied classes of Roses cultivated have to be passed over hurriedly; moreover, my time was short, but even with the probability of missing my train I was compelled to halt and admire the lovely Rugosa Madame Georges Bruant, its ample glossy leafage and exquisite elongated Niphetos-like buds being charming. It is worthy of extensive planting—if not in the Rose bed or Rose border proper, then in clumps, skirting lawns and shrubberies and similar positions, where it would prove as interesting and be as great a source of beauty and usefulness as its larger brethren

arc in more favoured spots. Let us hope that others of the same class in different colours will soon be added to the list.

Although this is a Rose nursery, we find many gems in shrubs suitable for sea-coast planting, and such as are too tender to winter safely out of doors in Cheshire. Hardy herbaceous plants, too, if not as yet in large numbers are in great variety, forming the nucleus of an extensive stock, and of such quality as the firm is already so deservedly noted for. The thriving condition of all the plants is apparent throughout the grounds, reflecting high credit on the skill and painstaking care of the manager of this branch, Mr. Heath.—JOHN ROBERTS, *The Gardens, Tan-y-bwlch, R.S.O., N. Wales.*

NEW IRISH ROSES.

I SUSPECT that others of your readers, as well as myself, felt disappointed by the announcement that Messrs. A. Dickson & Sons had sold their splendid gold medal Rose Mrs. W. J. Grant to an American nurseryman, because this will mean that we shall not be able to get it until the spring of 1894. There seems to be no possibility of denying "cousin Jonathan" when he sets his mind upon the acquisition of anything first-class, whether it be a thoroughbred Hereford or Derby winner, or, as in this case and that of Mrs. J. Laing and Her Majesty, a gem of the first water among Roses. And this Rose is certainly unique. La France is generally regarded as a hybrid, and hybrids are considered to be non-seed-bearing, yet this is a seedling from La France and Lady M. Fitzwilliam. Its colour, too, will ensure it a hearty welcome from lovers of old-fashioned flowers, for it is the true old bright rose-pink, and as sweetly scented as Roses were when Shakespeare uttered his oft-quoted dictum, "A Rose by any other name would smell as sweet." Add to this that it is constantly in flower from early June until frosts cut it off, and it will be conceded that our American friends are to be congratulated indeed.

But if we are disappointed about Mrs. W. J. Grant we must find consolation in the fact that Marchioness of Londonderry is still in the raiser's hands, and to make her début next spring. From the exhibitor's point of view solely this will probably prove the finest Rose yet seen. With Margaret Dickson Messrs. Dickson touched high-water mark, but with the Marchioness they certainly go a step farther, for the new comer is of a pure ivory whiteness, while the bloom is shaped like a first-rate example of Alfred Colomb, and about twice the size. The flower stem also is as thick as an ordinary lead pencil, and quite as sturdy, so that the flower stands as erect as an Oak, even after travelling twenty-four hours without water. As additional proof of its staying powers, I may say that a bloom so sent retained its form completely for three days after. No wonder this fine variety was awarded two special first prizes at the Ulverston Show. If it is beaten for the gold medal at the Crystal Palace next July its conqueror will have to be a wonder. The foliage is large and leathery, and the scent very distinct—something like a Magnolia. Judging by these two splendid novelties and others which have come to us from the same hands, the days of our dependence upon French raisers seem to have for ever passed away.—J. B.

STEAM VERSUS HOT-WATER HEATING.

IN order to determine whether steam or hot water were the best for heating greenhouses, a series of experiments have been made at the Agricultural Experiment Station in connection with the Cornell University (New York, U.S.A.), in which the following conclusions were arrived at:—1, The temperatures of steam pipes averaged higher than those of hot-water pipes throughout the entire circuit for the entire period of test. 2, The higher the inside temperature in steam pipes the less is the proportionate warming power of the pipes at a given point. The heat is distributed over a greater length of pipe, and as steam is ordinarily carried at a higher temperature than hot water, it has a distinct advantage for heating long runs.

3, When no pressure is indicated by the steam gauge, the difference between the temperatures of the riser and the return is greater with steam than with hot water. 4, Under pressure the difference is less with steam than with hot water. 5, There is less loss of heat in the steam risers than in the hot-water risers, and this means that more heat in the steam system is carried to the farther end of the house and more is spent in the returns as bottom heat. 6, This relation is more uniform in the steam risers than in the hot-water risers, giving much more even results with steam than with hot water. 7, When the fires are operative the fluctuation in the temperature of the risers at any given point is much greater with hot water than with steam.

8, An increase in steam pressure raises the temperature in the entire circuit, but the temperature does not rise uniformly with the pressure. 9, The first application of the pressure increases the temperature of the returns much more than that of the risers. 10, Steam is better than hot water for long and crooked circuits. 11, Pressure is of greater utility in increasing the rapidity of circulation of steam and in forcing it through long circuits and over obstacles. 12, Unfavourable conditions can be more readily overcome with steam than with hot water.

13, Hot water consumed more coal than steam, and was at the same time less efficient. This result would probably be modified in a shorter and straighter circuit with greater fall. 14, Under the conditions here present steam is more economical than hot water and more satisfactory in every way, and this result is not modified to any extent by the style of heaters used.

EVENTS OF THE WEEK.—The ensuing week will be rather a very busy one so far as metropolitan horticultural events are concerned. The great Show of Potatoes and fruit which opened at the International Horticultural Exhibition on Wednesday, continues to-day (Thursday) and Friday. The National Chrysanthemum Society will hold an Exhibition of October flowering Japanese Chrysanthemums at the Royal Aquarium, Westminster, on Wednesday, October 12th, continuing the two following days. The Conference Meeting will be held on Wednesday evening at seven o'clock. The customary sale of Orchids and other plants will take place at Messrs. Protheroe & Morris's auction rooms.

— **THE WEATHER IN LONDON.**—During the past week the weather has been cold and variable. On Sunday heavy rains fell, and the two following days opened fine, but towards evening the elements were again disturbed. At the time of going to press the weather is milder, but with every prospect of rain.

— **GARDENERS' ROYAL BENEVOLENT INSTITUTION.**—We are requested to remind our readers that the Anniversary Festival dinner of this Institution will take place on Tuesday, November 15th, at the Hotel Métropole, Lord Brassey in the chair. Applications for tickets should be made to the Secretary at 50, Parliament Street, London. It is also desired that collecting cards which are outstanding may be sent in before the above date.

— **ROYAL HORTICULTURAL SOCIETY.**—The attention of the Council having been drawn to a difficulty in the awarding of certificates, &c., to plants which have received * * * at Chiswick, passed the following minute at a meeting on October 4th:—"The Council request that in future whenever any plant (fruit, flower, seed, vegetable, &c.) shall have had * * * given it by a Committee meeting at Chiswick the Superintendent of the Gardens will (if it be possible) bring it forward at the next (or nearest possible) general meeting of the Society at Westminster or elsewhere in order that it may, if still thought deserving, receive a more definite award." The Council also passed the following minute:—"The definite award made under the above minute of Council will be given (as all the Society's awards are made) to the plant in question, and the custody of the certificate or other award will vest in the person sending the plant, &c., to Chiswick for trial."—W. WILKS, *Sec. R.H.S.*

— **DEATH OF MR. C. H. SHARMAN.**—It is with feelings of great regret that we have to announce the death of Mr. Charles Henry Sharman, who has for many years supervised our extensive establishment in Holborn under the direction of our managing partner. Those who have been favoured with Mr. Sharman's acquaintance will have observed that during the last twelve months he has not carried the same hale and hearty appearance that has characterised his bearing through a long series of years. If you will kindly give effect to a few lines in your columns expressing our deep regret at his sudden demise we shall feel obliged.—JAMES CARTER & CO. [All who were acquainted with the late Mr. Sharman will share in the regret of the proprietors of the great firm which he served so loyally and well. He died on the 28th inst., we understand from an apoplectic seizure, and was, we think, about fifty years of age.]

— **GARDENING APPOINTMENTS.**—We understand that Mr. J. F. Simpson, until recently foreman at Marton Hall, Middlesborough, Yorkshire, has been appointed head gardener to W. M. Smythe, Esq., The Lawn, Warwick, and has entered upon his duties. Mr. F. Kneller, late foreman to Mr. S. Bides, of Farnham, has also received an appointment in a similar capacity to the Marquis of Ripon, Studley Royal, Yorkshire. Mr. Jas. Bagshaw has been appointed to succeed Mr. C. W. Sharpe as head gardener to Edmund Peel, Esq., Bryn-y-Pys, Ruabon, Flintshire.

— **DEATH OF MR. C. EDMONDS.**—We regret to learn of the death of Mr. C. Edmonds, a well known grower of Cyclamens and Primulas, at Hillingdon, near Uxbridge. He died on September 17th, aged sixty-three.

— **STOCK PRINCESS ALICE.**—Among the different varieties of Stocks that I have grown this season this has proved the best. It is a pure white, and most useful for cutting, branching out from the stem. A row in the kitchen garden has been a mass of flower for the past four months; it is also an excellent variety for pots.—J. H.

— **MODERN FRUIT CULTURE.**—Under this title Mr. G. Bunyard sends us a pamphlet of thirty pages containing hints for amateurs and others, the articles being chiefly reprints from the catalogues of the firm, as well as papers read by Mr. Bunyard at meetings of the Royal Horticultural Society. The matter is therefore practical and useful.

— **EDGING FOR BORDERS.**—I shall be glad if any of your readers can tell me the most durable, most economical, and most pleasing edging for borders. I favour tiles, but these are so liable to get broken and are expensive; therefore if these are recommended from experience the price should be reasonable and perhaps may be stated.—W. M. B.

— **THE PEAR CROP.**—Our crop of all varieties of Pears on walls is very light this season, although there were plenty of blossom, but a few standard trees of Williams's Bon Chrétien, Marie Louise, and Beurré Clairgeau have carried heavy crops of fruit and with a clearer skin than has been the case for several years. No doubt the recent rains have been very beneficial to them, the fruit generally having greatly improved of late.—J. H.

— **PEACHES IN THE OPEN AIR.**—At a recent meeting of the members of the Wakefield Paxton Society Mr. J. Campbell, gardener to Mrs. J. H. Micklethwaite of Painthorpe, read an essay on "Stone Fruit." The essayist, who is a successful fruit grower, dealt with his subject in an interesting and thoroughly practical manner. Mr. Campbell contended that it is quite possible to grow Peaches in the open air in the neighbourhood of Wakefield, and said that he had grown them thus with success.

— **GREENHOUSE RHODODENDRONS.**—Mr. Bardney writes:—"Where a delicate pink is needed for table decoration at this period of the year and the following three or four months, Rhododendron Princess Royal (greenhouse variety) should be grown in quantity. This variety grows freely under suitable conditions, and when fully exposed to the sun every point will bloom. The plant naturally produces its flowers in succession, and on this account it is the more valuable for the purpose for which it is recommended. I have not tried it planted out, but intend to do, as I believe it will grow with much greater freedom than when kept in pots."

— The same correspondent observes:—"There will be no lack of variety amongst greenhouse Rhododendrons, if we are to judge from the large number of seedlings raised from crosses now flowering and about to flower for the first time in the Handsworth Nurseries, Sheffield. The type followed appears to be that of jasminiflora. Several plants with blush and delicate shades of pink blooms were in flower, and which, as far as I could form an opinion, will prove worthy additions to the varieties already in commerce."

— **SILVER BEET.**—Attention may fittingly be drawn to the Silver or Seakale Beet as a valuable vegetable, which should be grown in all gardens where Seakale is appreciated. By many the midribs of this Beet are preferred to Seakale. One or two rows will yield an abundant supply if given liberal treatment. It requires land that has been well worked and liberally manured. It should not be sown too early, or it is liable to run to seed in early autumn.—A GARDENER.

— **THE CURRANT CROP.**—Currants are likely to be dear this Christmas. The new crop, according to the letter of a Bristol house, Messrs. Wedmore & Co., is the smallest for many years. The reduction in weight by disease, they say, has been generally understated. This disease, a kind of mildew (the Greek *Peronosperos*), suddenly attacked the Vines when the fruit was maturing, and seems to have withered up and destroyed the bunches. The greatest damage has been done in the district of Pyrgos, where the crop turns out only 15,000 tons, against 40,000 tons last year. In the islands Zante and Cephalonia the crop is 12,500 tons, against 20,000 tons last season. These important districts, therefore, have together produced less than one-half of last year's yield. The other districts have suffered more or less seriously. Supposing them to produce 80,000 tons against 100,000 last season the "shortage" on the total crop of Currants will be over 50,000 tons. In the last three seasons the average consumption of Currants in the world has been 149,000 tons. There are only four tons of Currants this year against every five tons last year. France, we are told in the letter above quoted, is likely to use Currants largely for wine making this season, as the vintage in that country is a small one, and must be supplemented from other sources.

— PEACH MAGGOT.—Perhaps "J. B." would send, in a tin box to the Editor, specimens of the maggot complained of on page 282, as then one could better judge of the mode of treatment.—ENTOMOLOGIST.

— A PROPOSED NEW PARK.—It is stated that a project is on foot for the acquirement of the ground occupied by the "Wild West," at Earl's Court, as a public park. The space is about 6 acres in extent, and it would be of considerable value for the purpose named. By adding the adjoining site of the International Horticultural Exhibition a park of some pretensions would be acquired.

— SUBURBAN ALLOTMENTS.—According to the *City Press*, the Leathersellers' Company have granted a seven-years lease of between five and six acres of their land at Catford, a south-eastern suburb of London, for the purpose of garden allotments for the poorer residents of that locality. Between thirty and forty applications have already been made for the land, and there will be room for ten or twenty others this autumn.

— PRESENTATION TO A NOTTS GARDENER.—Mr. J. H. Walker, who was for many years gardener to the late John Wesley Lewis, Esq., of Hardwick House, Nottingham, was presented on the 28th ult. by his friends at Radford with a very handsome watch and chain, in addition to a magnificent gold scarf pin, as a token of respect on his leaving Nottingham to fulfil his engagement as lecturer to the Leicestershire County Council.

— CARTER'S HOLBORN PROLIFIC POTATO.—I am very pleased to report favourably of this distinct, handsome, and really first-rate new Potato. It is a good cropper; the tubers partake very much of the character of Woodstock Kidney in shape, colour, and quality; in short, Holborn Prolific is everything that constitutes an excellent all-round Potato, the pebble-shaped tubers being of good appearance, having few, scarcely perceptible, eyes, and like balls of flower when cooked. Holborn Prolific is destined to occupy a prominent position at future exhibitions of the "noble tuber."—H. W. WARD.

— A FLOWER SHOW AT HOVE.—The Committee of the Hove Industrial and Horticultural Society have once more to be congratulated upon the success of their annual Exhibition (the fifteenth of the series) held at the Hove Town Hall recently. The steady increase in the number of exhibitors and exhibits is evidence of the popularity of the shows. This year the exhibitors numbered 593 as compared with 554 last year, their productions reaching a total of 1180, or 47 more than was the case last year. Messrs. Baldwin & Sons lent a large number of plants for decorative purposes.

— A NEW STYLE OF ROOFING GREENHOUSES.—When I called last week at Messrs. Keynes, Williams & Co.'s nursery, the latter member of the firm drew my attention to a somewhat novel method of roof making and closing of a large span greenhouse. The rafters were composed of iron in small furrow or V-shapes, being about 1½ inch deep, and 2 inches broad on the upper side. The panes of glass, 14 inches by 16 inches, rested on a bed of putty one-third of an inch in width, laid on to the projecting ledge on each side. Thus, when the glazing was complete, the rain water falling on to the glass ran into the furrows of the rafters, and being in that way carried off, effectually prevented drip of any kind. The ironwork received a coating of rough varnish, and thus prevented rusting. To render the newly glazed roof secure, pieces of copper wire were placed at intervals under the rafters and the ends bent over, made just to press upon the glass the width of the putties, then beneath, with a pair of pincers, a turn or two was given to the wire and it was made absolutely tight. In that way the glass was made in the fiercest storms absolutely wind and watertight.

— ROSA POLYANTHA AS A STOCK.—Mr. Williams also showed me, in a large collection of early spring grafted pot Roses, now standing outdoors, a plant of Niphetos worked on to this stock that had done wonderfully well even as compared with plants on the Manetti. He thinks it is a capital stock for many varieties for pot culture, but advises that it be not trusted for outdoor purposes, as he has found it to suffer severely in hard weather. It is well to be advised by so good an authority in such a matter.—D.

— FROST AND DAHLIAS.—"We had," said Mr. Williams, "one of the most promising lots of seedling Dahlias I ever saw on the 17th of September, and I purposed making a fine show of them at the Drill Hall on the following Tuesday. The severe frost, about 6°, of the morning of the 18th, however, fully settled every plant, and caused a wreck that was piteous to behold. It was a case in which one had need of the profoundest philosophy."—A. D.

— CASSIA CORYMBOSA.—The finest specimen I have seen of this plant is growing in the conservatory at Rooksbury Park, near Fareham, in this county. It is a very old one judging from its appearance, but gives good crops of flowers annually. It reaches fully 20 feet high and is 10 feet in diameter. It is pruned every year, the young growth giving abundance of bright yellow flowers, which are charmingly set off by the dense green leaves for which the plant is noteworthy when in health.—E. M., *Hants*.

— SEPTEMBER RAINFALL IN SUSSEX.—The total rainfall at Cuckfield, Sussex, during the past month was 2.06 inches, being 1.07 inch below the average. The heaviest fall was 1.04 inch on the 29th. Rain fell on twelve days. The rain for the nine months is 15.41 inches, which is 4.86 inches below the average. The highest temperature was 70° on the 12th; lowest 39° on 18th. Mean maximum, 63.2°; mean minimum, 48°; mean temperature, 55.6°.—R. I.

— DAHLIAS AT CHELTENHAM.—A mistake occurs in your report of the Cheltenham autumn Show. "Dahlias were of extra quality. Messrs. Heath & Son secured premier honours for twenty-four distinct varieties." So far quite right. The second prize was awarded to Mr. Thomas Hobbs, Easton, Bristol; Mr. Newman, Kingswood, third; Mr. G. Maylett, Worcester, fourth. Seven stands were staged, and considering the severe frost on the morning of Sunday the 18th, the blooms were of extraordinary good quality. Mr. Garaway of Bath as reported did not exhibit Dahlias. Please note in your next issue.—THOMAS HOBBS, F.R.H.S.

— REPORT OF THE WEATHER AT HAMELS PARK, BUNTINGFORD, HERTS, DURING SEPTEMBER, 1892.—While some correspondents of the *Journal* complain of a very light rainfall, I am glad to say we had sufficient. A very disastrous frost occurred on the morning of the 21st, when Dahlias, French Beans, &c., and even Chrysanthemums, was blackened by it. Rainfall on twelve days during the past month. Maximum in any twenty-four hours was 0.86 on the 21st; minimum, 0.02 on the 25th. Total during the whole month, 2.62, against 1.18 of 1891.—E. WALLIS.

— THE DEVON AND EXETER GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.—The annual business meeting for the election of President, Vice-Presidents, Secretaries, Treasurer, and Committee for 1892-93, was held in the Council Chamber of the Guildhall on Wednesday evening, the 28th September. The following excellent autumn programme has been arranged for the session 1892-93. Wednesday, 5th October, Mr. J. McCormick, Wear House Gardens. Subject:—"Grape Vines and their Cultivation." Wednesday, 19th October, Lieut. Percy Smith, Devonshire Regiment, Higher Barracks. Subject:—"Lilies and their Culture." Wednesday, 2nd November, Mr. J. Stoneman, Teacher of Botany at Exeter Museum. Subject:—"How a Scientific Knowledge of Plant Life can help a Gardener." Wednesday, 16th November, Mr. G. B. Carlile, Topsham (late of Martin's Lane). Subject:—"Fruit: its Selection and Handling—from a Fruit-salesman's standpoint." Wednesday, 30th November, Mr. J. Mayne, Bickton Gardens. Subject:—"The Cyclamen: its Culture and Value as a Decorative Plant." Wednesday, 14th December, Discussion on papers read last Session, to be opened by Mr. W. Mackay.

— LACHENALIAS IN BASKETS.—In no other form do these plants produce a better effect than when growing in baskets, especially the variety tricolor, its natural pendulous habit rendering it particularly suitable. The present is a good time to make new baskets or re-arrange the bulbs in the old receptacles, as growth is just beginning. Under good cultivation the bulbs increase fast, so that a selection in various sizes is easily obtained. For suspending in a conservatory or greenhouse a splendid effect can be secured by the aid of a few of these baskets, the rich green of the leaves contrasting well with the three-coloured flower spikes. A cool Peach house is a capital place to grow them in until flowering time; the air required for the Peaches seems to suit the Lachenalias to a nicety. Abundance of water is needed when the plants are growing freely. When the flowers and foliage fade water is entirely withheld from them, and the baskets are hung up in a cool shed until growth commences afresh. Massive baskets, 18 inches in diameter and about 15 inches deep, make the finest display. I have seen many small baskets employed, but none look so well as those mentioned. Galvanised wire (No. 8 size) is more suitable than wood for making them, as it is easily hidden by the moss with which the inside of the basket is lined to retain the soil. The bulbs are put in in layers 3 inches apart for the strongest, and a trifle less for weaker ones. A compost of substantial materials, such as fibrous loam, cow manure, and leaf mould, three parts of the former to one of the latter, will grow good Lachenalias.—E. M.

— PROFIT IN PRUNES.—A writer in the American "Pomona Progress," basing his estimates on the profits of his own Prune orchard and the figures given him by four of the most careful growers in Pomona Valley, California, makes the rosy statement that 10 acres planted with French Prunes will, within ten years, yield an annual net income of £1000. The outlay for such an orchard during the first four years will be something less than £600, including interest. This outlay will be nearly equalled by the crop of the fifth year, while a handsome profit is assured the next season.

— FLAVOUR IN TOMATOES.—The theory that yellow Tomatoes invariably have a higher flavour than red ones will not bear examination. To assume that mere difference in the colour of the skin and flesh, without any change in the texture or composition of the flesh, will enhance flavour, is too absurd. It is like the opinion that white blossomed runner Beans have better flavoured pods than scarlet flowered ones, and yet one is but a colour sport from the other. Flavour will be found in Tomatoes very much just as the plants have been grown in ample light, and have not been over-watered or fed. There can hardly be too much sunlight or warmth to make Tomatoes good. A very handsome looking yellow plum-shaped Tomato shown at the Drill Hall last week was found to be more flavourless than any of the red ones. It is only to start a theory and plenty of disciples are discovered, yet it is generally found that the theory has no tangible basis.—D.

— VICTORIA ASTERS.—This section of annual Asters have been unusually good during the present season, and have well sustained their character for usefulness in the months of August and September, not only as border plants, but for cutting purposes. The range of colour that is procurable in this section renders them both valuable and interesting. Distinct hues can now be had from separate packets of seed. We have a long border filled with Roses, and enough space is allowed in the front for one row of the Victoria Aster and another in front of it of the dwarf Chrysanthemum-flowered section. When the Roses have passed their best, as is the case in August, the Asters maintain the border in a bright condition. Like most annuals Asters do best in a rich soil. We have plenty of plants this year carrying a dozen good blooms, which would be considered far too many if exhibition was the aim, but as decoration of the garden, combined with providing cut flowers, is the object, the more blooms the plants produce the better. Where so many persons make a mistake in growing Asters, as well as with other half-hardy annuals, is in giving too much heat when preparing the plants. When this is the case they are weakened in their infancy, and cannot afterwards give good blooms, nor a quantity of them. A cold frame is all the protection our plants have, but we sow the seed the first week in March, ample time is then allowed for a gradual steady growth. The plants when in bloom never exceed 1 foot high. One stake in the centre of each plant prevents the weight of the blossoms from over-balancing the plants.—S.

— EMIGRANTS' INFORMATION OFFICE, 31, BROADWAY, WESTMINSTER, S.W.—The October circulars of the Emigrants' Information Office, and the annual editions of the penny and other handbooks, with maps, show the present prospects of emigration. The Canadian Government is offering bonuses of five to ten dollars a head to those who take up land in the North-West or British Columbia. The Government Immigration Agencies in the Province of Ontario have just been abolished. Emigrants are warned that the system which exists of paying premiums in this country for instruction in farming in Canada is liable to grave abuse, and is considered by the Canadian Government to be unnecessary. Sydney, in New South Wales, suffers, as usual, most of all from the prevailing depression, and no one without money should go there at the present time unless he has work waiting for him. In country districts there is work to be had on vineyards, stations, and farms, especially at this season of the year. In South Australia almost the only demand last quarter was for ploughmen, shearers, and general farm and station hands, of whom, however, there was a plentiful local supply. In Queensland the re-introduction of the Pacific Islanders to work on the sugar plantations, which has lately been authorised by the Government, has given an impetus to sugar growing, and consequently to the manufacture of machinery for plantation and agricultural purposes, but there is no demand for fresh hands. In South and Western Australia, Tasmania, Cape Colony, and Natal there is a demand for small capitalists, farmers, and fruit growers. As the Brazilian Government are endeavouring to introduce European labourers into some of the tropical provinces of Brazil, it becomes necessary to repeat again most strongly the warnings which have been frequently issued from this office against British emigration to that country.

— A NEW INDUSTRY FOR FOREST DISTRICTS.—Mr. W. S. Manning writes from 2, Gray's Inn Road, London: "As your valuable paper circulates in many woodland districts allow me to make the following suggestions for those interested in forestry, or the welfare of their poor neighbours. A new industry might be gradually started where hedge nuts or beech nuts abound, and permission can be obtained to gather them, if these nuts could be gathered and sent up to London or other large towns. Both could be sold at 2d. per lb., or by the cwt. at 10s. to 12s. in any quantity, and the kernels would sell at 5d. per lb. The shelling would afford evening work for the elder children during the autumn months, and I shall be glad to find an outlet for the first 200 or 300 lbs. offered, and pay cash on delivery at a London railway station for either of these nuts on the above terms to make a start. To secretaries of gardeners' societies I may add that I shall be glad to give an address or open a debate on what is man's best and natural food free of any charges."

— SUMMARY OF METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, WORKSOP, NOTTS, IN SEPTEMBER.—Mean temperature of month 54.1°. Maximum on the 19th, 67.4°; minimum on the 18th, 36.1°. Maximum in the sun on the 25th, 124.1°; minimum on the grass on the 18th, 27.4°. Mean temperature of the air at 9 A.M., 55.5°. Mean temperature of soil 1 foot deep, 54.8°. Nights below 32°, in shade, none; on grass, 7. Total duration of sunshine in month, 109 hours, or 29 per cent. of possible duration. We had four sunless days. Total rainfall, 1.74 in.; maximum fall in twenty-four hours on the 20th, 0.99 in. Rain fell on thirteen days. Wind, average velocity 11.0 miles an hour; velocity exceeded 400 miles on one day, and fell short of 100 miles on one day. Approximate averages for September:—Mean temperature, 55.5°; sunshine, 110 hours; rainfall 2.26. A rather cool, but otherwise fairly normal month. The first three weeks were fine. The bulk of the harvest was secured in good order, but the rest of the month was showery and unsettled.—J. MALLENDER.

— CHOLERA PRECAUTIONS AND HORTICULTURAL IMPORTS.—It is feared by the importers of seeds and bulbs that the precautions against cholera may kill or keep out of the country a good many plants besides the comma bacillus. The long delays at quarantine in the close holds of steamships will injure many seeds and bulbs and kill many living plants outright. Besides this a delay at this season of active opening of the autumn trade is most annoying, and it will cause much disturbance if not pecuniary loss. Many invoices have not yet left the other side, and importers hardly know whether to countermand their orders or allow the stock to take the chances of quarantine delay, and what is still more dangerous, of quarantine disinfection. It may be that some of the vapours used to destroy cholera germs will not kill Holland bulbs, for example. But some of the processes in which hot steam is used to kill the comma bacillus by sheer heat would be likely to cook bulbs beyond all hope of germination. We hope the dangers of the situation are not so serious as some have feared. Importers will doubtless order shipment only from clean ports, and if health officers use proper judgment in selecting their modes of disinfection seeds and bulbs ought to escape without injury. But it is well worth while for the importers of stock of this character to make a united effort to secure fair treatment. Thus writes "Garden and Forest" (American). Happily there is no cause for precautions with British exports.

— A DISTINCT SINGLE BEGONIA.—Any good break in these flowers is welcome. I saw on Sunday last, when taking a stroll round the outskirts of that fine Somersetshire town Yeovil, what was evidently a very brilliant display of Begonias in a show house, over which was the name of Mr. B. R. Davis. To pass such a show, even though recently pretty well satiated with Begonias, was against gardening nature. I therefore found Mr. Davis, and had a close view of his beautiful single and double flowers. They have not all the good things at Forest Hill or Swanley by any means, but it does seem a surprise to find Begonias in such splendid form at Yeovil. The gem of the collection, however, in my estimation, was a striking single crimson, the flowers being both five and six petalled, large, flat, and regularly placed. One of the blooms there was 6 inches across, but others have exceeded 7 inches. That will show that the variety has the merit of size, as well as the novelty of surplus petals. The sort is four years old, and first gave four-petalled crimped-edged flowers; then came the following year six petals, in all cases of large flowers. The following year they produced five petals, and now this year they have been six again, except in the case of one late bloom. Here is the prospect of a break, which should give to us quite a new and even more beautiful strain of Begonias than we now possess. Mr. Davis promised he would do his best to send the flowers to the Floral Committee.—ALEX. DEAN.

A FINE WEEPING ASH.

THE engraving (fig. 42) has been prepared from a photograph of a fine Weeping Ash standing at the south-western corner of the lawn at Benham Park, Newbury. Its height is about 30 feet and its circumference 90 feet. The age of the tree is not known, but it has been planted upwards of thirty years. Mr. J. Howard, the head gardener, informs us that the circumference of the tree was much the same when he first saw it fourteen years ago, but that it was then allowed to make a new leader and has since nearly doubled its height. There are doubtless many taller specimens than this, but perhaps few so symmetrical in growth. As may be seen there is an opening in the tree, and it has occasionally

NOTES ON CROCUSES.

THE Crocus with its rich yellow, purple, pure white, blue and lilac flowers is a prey to a variety of pests. Its flowers have a peculiar charm for sparrows and rooks, while mice seem to delight in devouring the corms, and rabbits the foliage. What difference there may be in the corms I do not know, but mice have a particular liking for those which bear yellow flowers. I have known them to destroy nearly every yellow one, while whites, purples, and striped kinds have not been touched. A slight syringing with petroleum and water will often prove effectual in the case of rabbits.

The Crocus is a sun-loving plant; it will grow in the shade, but it seems to lack the bright brilliant hue that is so characteristic of the flowers when grown in open sunny spots. It is less useful for growing

FIG. 42.—WEEPING ASH IN THE GROUNDS OF BENHAM PARK, NEWBURY

been used as a resort for tea and refreshments at tennis parties. The photograph, which is an excellent one, was taken by Miss Myers.

The tree on the right of the Ash is a Beech in ill health, and is condemned to come down in the winter. Another effective tree on the lawn is a good specimen of the Golden Yew, which a month ago was in full summer beauty. Near the Ash is a plant of *Chamærops humilis* over 20 feet high; it was removed from the conservatory last year and stood the test of the winter fairly well, but when the cold winds of March came it was severely cut. It has lately made a number of new leaves, and Mr. Howard hopes to get it permanently established.

in grass than the Snowdrop, because its foliage is considerably longer in dying and thus prevents mowing. Crocuses should never be planted in the grass where it is necessary to keep it neat and short. In woods, by the side of woodland walks and in any semi-wild place, they are delightful springing naturally from amongst the grass. In these positions the foliage can ripen off naturally before it is necessary to mow the grass. Cut off the foliage while it is green, continue the practice for a few seasons, and the Crocuses will quickly degenerate. The yellow, white, and light forms are the best for planting in grass. Crocuses, like Snowdrops, should always be planted in positions where they can remain undisturbed until it becomes necessary to lift them through overcrowding. They are charming for association with the flowers named, and the

departing beauty of the one does not appear to mar in the least the brilliancy of the other. For garden decoration Crocuses are extremely cheerful, and when planted in large numbers they add a bright, even a picturesque effect if carefully and judiciously planted.

Crocuses are far more particular about the soil in which they are grown than Snowdrops. Although they live, flower, and to some extent flourish in poor soil, they do not increase so rapidly, grow so strongly, or produce such large flowers as when grown in good fertile soil. But this is not the main point; they must have a drier and warmer soil than Snowdrops. In the Lincolnshire fens, where Snowdrops can be well grown for sale, some of the land is too wet and cold for the well-being of Crocuses. On any light, warm, dry soil their culture for market might be taken up with advantage. Large quantities are grown for sale in Lincolnshire and other places, but even larger quantities are annually imported, which could be equally well grown if cultivators would only set about doing so. If small cultivators of land would commence growing such bulbs as Crocuses with the same zeal and energy that many display with bulbs of different kinds in the neighbourhood of Dorrington, and other districts near Spalding, they would find it far more remunerative than many things that they grow in small quantities, and have therefore a difficulty in finding a good and ready market for. There is land far more suitable for bulb growing than that in the neighbourhood to which I have referred.

Crocuses are more generally forced than Snowdrops, and this is due doubtless to the more striking appearance of their flowers. Where flower forcing is carried out on a large scale and conservatories are kept gay with a variety of plants that flower months before their natural time a few Crocuses should certainly be grown, but they ought to precede those flowering outside or their culture in pots is best left alone. The corms should be obtained for this purpose by the end of August or the first week in September at the latest. I have found some difficulty in getting them as early as I should like; whose fault this is I do not know. One thing is certain, they leave the home grower in time to be in the market ready for distribution by the end of August. Four and 5-inch pots are the most suitable. The latter are preferable and should contain as many corms as can be conveniently placed in them. I believe in covering the bulbs with an inch of soil and leaving room in the pots for watering. The pots should be plunged in the usual way, or covered with 2 inches of fine coal ashes until they are full of roots and signs of top growth are visible. The plants should not be allowed to grow too long before they are removed to a cold frame. The best method is to place the pots in cold frames and to sprinkle between them some cocoa-nut fibre refuse so as to fill the pots level with the rim and allow the plants to grow through. They will progress rapidly under these conditions, and if finally removed to a house where the temperature averages about 45° they will come forward almost naturally into flower. They need plenty of water, and should never be allowed to become dry. They ought never be placed on dry shelves, and they should not be hurried, as they resent any attempt at forcing. Subject them to an undue share of forcing, and they will either go blind or be longer in coming into flower than if brought forward under more natural conditions.

For a good many years I have been engaged in forcing Crocuses, and the earliest flowers, though perhaps not the finest, can be had by looking after the plants well after flowering and forcing them the second year. A few only should be retained for this purpose, because for successional batches the cost of the labour is more than new bulbs can be purchased for. My remarks on growing Crocuses in pots only deal slightly with those grown specially for the exhibition stage. For this purpose much larger pots are generally used, and if there is one difficulty to contend with it is that of keeping back the plants for the date of the show. In some seasons they come almost naturally into bloom at the desired time, and therefore there is not so much skill required in having good pots for showing as to have them in flower early in the season.—WM. BARDNEY.

ROYAL HORTICULTURAL SOCIETY.

OCTOBER 4TH.

A MORE than usually interesting display awaited visitors to the Drill Hall on this occasion, for apart from the Michaelmas Daisies, which were expected to be the most prominent feature, there was a varied assortment of plants and flowers, a brilliant show of Orchids, and a magnificent display of fruit. Messrs. Cheal & Son had a superb collection of Apples and Pears; while A. H. Smee, Esq. (gardener, Mr. Cummins), and the Dowager Lady Freake (gardener, Mr. Rickwood) also had excellent displays.

FRUIT COMMITTEE.—Present: Philip Crowley, Esq. (in the chair), with Rev. W. Wilks, Dr. Hogg, and Messrs. John Lee, T. F. Rivers, P. Veitch, G. Bunyard, J. Cheal, G. Taber, H. Balderson, J. Hudson, G. Wythes, G. Sage, W. Bates, C. Ross, A. Dean, G. Cummins, Harrison Weir, J. Willard, and J. Wright.

A dish of *King Harry Apple* was sent from Chiswick as a free bearing useful variety, very tender, sprightly, and juicy (award of merit). Messrs. S. Spooner & Sons, nurserymen, Hounslow, sent an Apple called *The Baron*, a handsome looking fruit, like a richly coloured Queen. The Committee desired to see it again later in the season.

Mr. C. Ross sent two dishes of Apples, seedlings from *Golden Reinette*. No. 1, was transparent, attractive, but over-ripe; No. 2, coloured, not remarkable for quality, but an award of merit was accorded. Mr.

Edmonds, The Grange, Gillingham, Kent, sent a dish of an Apple named *Empress*, a seedling from *Dumelow's Seedling*, good in appearance, but though no doubt useful, was not regarded as an advance on existing sorts. Mr. James Miles, Normandy Farm, Kent, sent a dish of small well-coloured Apples called *Duchess of Kent*, but the variety was not considered better than *Col. Vaughan*.

Mr. T. Francis Rivers placed on the table a dish of *Rivers' Codlin Apple*, a conical variety of good size, raised from American Mother. Mr. Barron had tested the fruit in a cooked state and pronounced it excellent. Tree a free bearer, and the fruit is said to keep till March (first-class certificate).

Mr. Barron placed on the table bunches of the *White Gros Colman Grape* grown at Chiswick. It was raised by the late Mr. Roberts of Charleville, and has been previously before the Committee. The Vine was sent to Chiswick by Messrs. Dicksons, Limited, Chester. The berries in shape and size resemble the type, but are more sweet, juicy, and refreshing (first-class certificate). Mr. Barron also submitted bunches of *Royal Muscadine* and *Chasselas Vibert*, the last being of twice the size of the former, earlier, and better. An award of merit was granted for it as a cool greenhouse and outdoor Grape. Mr. G. C. Ritchings, gardener to D. Frankland, Esq., sent a Melon, the result of a cross between *Read's Scarlet* and *Hero of Lockinge*, a variety of promise, which the Committee desired to see in the summer.

Mr. Willard, Holly Lodge, Highgate, sent cooked and uncooked heads of *Adam's Early Maize* from plants sown in the open in April and May. The flavour was good, and an award of merit was accorded.

Mr. J. Simpson, Dallis Hill, Kilburn, sent Tomatoes *x Perfection* and *Main Crop*. The variety was recommended to be grown at Chiswick. Mr. Hudson sent very fine fruits of Tomatoes, the produce of plants grown in ashes (cultural commendation). He thought, and most of the Committee were of the same opinion, that Tomatoes are often grown in too rich soil. Mr. R. Owen, Maidenhead, sent good and highly coloured Tomatoes resembling *The Conference*. Mr. J. Wilson, Glenlee Gardens, Hamilton, N.B., sent a Cucumber, very large, like an Indian club, altogether too overgrown for southerners. Mr. Leach, Albury Park, sent good specimens of Lettuce, and was accorded a vote of thanks. Mr. A. J. Brown, the School of Handicraft, Chertsey, sent a small collection of Apples and Pears, from trees planted in 1890 (vote of thanks). Mr. John Cook sent very good *Reine Claude de Bavay* and *Coe's Golden Drop* Plums, and a dish of Peaches; a vote of thanks was accorded.

Mr. Rickwood, gardener to the Dowager Lady Freake, Tubwell Park, Richmond, sent forty dishes of admirably grown Apples and Plums, and a small silver medal was recommended.

A. H. Smee, Esq., Hackbridge, (Mr. G. W. Cummins, gardener), exhibited sixty dishes of Apples fine in size and colour, and a silver Knightian medal was recommended. Messrs. J. Cheal & Sons, Crawley, staged 140 dishes of remarkably fine Apples and Pears, and a silver-gilt medal was unanimously recommended.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair), Messrs. J. Laing, B. Wynne, R. Dean, R. Owen, H. Herbst, E. Bause, G. Phippen, G. Nicholson, F. Ross, W. C. Leach, N. Davis, C. E. Pearson, C. J. Salter, W. Bain, C. Jeffries, J. T. Bennett-Poë, T. Baines, J. Walker, John Fraser, G. Paul, W. Goldring, C. T. Druery, W. Furze, and G. Gordon.

Messrs. J. Veitch & Sons contributed *Hymenanthera crassifolia* (see below), *Caryopteris mastacanthus*, *Amasonia punicea* (cultural commendation), *Rhododendron multicolor Neptune* (see below), and a splendid box of *Streptocarpus*, well illustrating the great advance that has already been made with these. Messrs. B. S. Williams & Son showed *Clivia Autumn Beauty*. Mr. W. C. Leach, Albury Park Gardens, Guildford, contributed *Hippophaë rhamnoides*, *Rosa polyantha japonica* and *Rosa rugosa*, also pots of *Mignonette Her Majesty* from seed sown in June. A vote of thanks was accorded. Mr. W. Wells, Earlswood, sent a collection of Chrysanthemums, for which a bronze Banksian medal was awarded. He had a large box of the yellow Japanese *William Wells*, together with good blooms, considering the earliness of the season, of many well-known varieties. Mr. H. Elliott, Stourvale Nursery, Christchurch, sent a collection of Nerines, of which *corusca major*, rich scarlet, and *c. m. sarniensis*, very deep rose, were the best. Messrs. Pitcher & Manda sent *Anthurium crystallinum fol. variegata* and *Adiantum cuneatum fol. variegata*. Both, however, were passed. Mr. Owen sent Chrysanthemum *Madame Zephyr Lionnet* and two English seedlings, named *General Hawkes* and *Lady Brooke* (see below). The Rev. W. Wilks sent a few perennial Asters; Mr. Fry, a small yellow Carnation, named *Buttonhole*; and Mr. Rawlings, *Dahlia Mrs. Vagg* (see below).

Messrs. Peter Barr & Son, Covent Garden, staged a most interesting collection of Asters, prominent amongst which were *Aster amellus majus*, *Aster ericoides*, *A. ericoides Cleo*, *A. puniceus pulcherrimus*, *A. novæ-angliæ roseus*, *A. vimineus*, *A. cordifolius*, *A. umbellatus*, *A. cordifolius elegans* and *multiflorus* (silver Banksian medal). An excellent collection of Asters was sent from the Royal Horticultural Society's Gardens, some very fine varieties being staged. *A. corymbosus*, *A. trinervis*, *A. paniculatus* var. *W. E. Grant*, *Aster acris* var. *nanus*, *A. versicolor* var. *Antigone*, *A. amellus* var. *bessarabicus*, *A. amellus* var. *majus*, *A. umbellatus*, *A. linoxyris*, *A. puniceus* var. *pulcherrimus*, *A. novæ-angliæ* var. *Melpomene*, *A. novi-Belgii*, *A. lævis*, *A. novæ-angliæ* var. *præcox*, *A. novi-Belgii* var. *Horace*, *A. Arcturus*, *A. longitoliolus formosus*.

Messrs. E. D. Shuttleworth & Co., Fleet, Hants, sent a group of

hardy perennials, amongst which *Tritoma Uvaria*, *Rudbeckia laciniata*, *Pyrethrum uliginosum*, *Helenium autumnale*, *Rudbeckia Newmanni*, *Aster nivea*, *A. amellus* *bessarabicus*, *A. puniceus* var. *lucidus*, *A. novæ-angliæ rosea*, *A. Robt. Parker*, and *A. Curtisi*. A bronze Banksian medal was recommended. Henry Southall, Esq., The Craig, Ross, also staged a collection of Asters. Mr. Thos. Ware staged a charming group of *Nerines*, including *pumila*, *sarniensis*, *coruscans* major, excellens, *amabilis*, *Planti*, and *flexuosa*. He also staged four plants of *Iris alata*, a very beautiful species and remarkably fragrant, for which a vote of thanks was accorded. A small group of tree Carnations was staged by the same exhibitor, amongst which were J. Jassand, Marie Forest, Irina, flavium, Auguste Cotton, John Broughton, Rose Rivoire, Lucifer, and Field Marshal.

Messrs. H. Cannell & Sons, Swanley, sent flowers of the double *Begonia* Rosebud, also a few fine trusses of Zonal Pelargoniums. Messrs. J. Laing and Sons, Forest Hill, were accorded a vote of thanks for a small group of *Saxifraga sarmentosa* *tricolor superba*, which is a pretty and effective little plant. Mr. Crook, gardener to W. H. Evans, Esq., Forde Abbey, Chard, Somerset, staged a small group of Asters, and a collection of hardy border plants, for which he received a vote of thanks. Mr. Thos. Hobbs showed three good blooms of *Dahlia James Hobbs*.

Mr. A. Waterer, Woking, staged, amongst other shrubs, two hampers of *Pernettyas* (silver Banksian medal). Mr. H. Elliott, Stourvale Nursery, Christchurch, sent half a dozen *Dracenas* in variety (see below).

Prizes were offered for hardy perennials. For a collection of eighteen bunches the Earl of Dysart, Ham House, Richmond (Mr. Sage, gardener), took the first prize, showing *Eryngium Oliverianum*, *Helenium autumnale*, *Aster lævigatus*, *Rudbeckia Newmanni*, *Helianthus multiflorus plenus*, *Gypsophila paniculata*, *Pyrethrum uliginosum*, *Lilium auratum*, *Erigeron speciosus*, *Phloxes*, *Helianthus decapetalus*, and some fine bunches of Asters. The first prize for twelve was awarded to W. E. Hall, Esq., Coker Court, Yeovil (Mr. Horley, gardener), who staged fine bunches of *Lilium tigrinum splendens*, *Helenium Hooperi*, *Sedum spectabile*, *Gladiolus ramosus* *Princess Clothilde*, *Iris*, *Anemone japonica alba*, *Rudbeckia Newmanni*, *Pyrethrum uliginosum*, *Phygelius capensis*, *Helianthus latifolius*, and Asters. The second prize was won by Mr. James Gibson, The Oaks Gardens, Carshalton, who exhibited *Rudbeckia occidentalis*, *Statice*, *Chrysanthemum maximum*, *Helianthus decapetalus*, *Aster Robert Parker*, *Lilium lancifolium rubrum*, *Rudbeckia Newmanni*, *Aster lævigatus*, *Aster amellus*, *Helianthus multiflorus plenus*, *Pyrethrum uliginosum*, and *Anemone japonica alba*. Mr. J. Hudson, Gunnersbury House, gained the first prize for a collection of eight hardy perennials, staging *Pyrethrum uliginosum*, *Rudbeckia Newmanni*, *Phlox scedling*, *Asters Robert Parker*, *A. bessarabicus*, *A. leucanthemum*, *Eryngium amethystinum*, *Helianthus multiflorus maximus*. Miss Debenham, St. Peter's, St. Albans, was second with *Aster longifolius formosus*, *Sedum spectabile*, *Solidago virgaurea*, *Aster novi-Belgii*, *Pyrethrum uliginosum*, *Gaillardia grandiflora*, *Aster novæ-angliæ*, and *Rudbeckia Newmanni*.

ORCHID COMMITTEE.—Present: H. J. Veitch, Esq. (in the chair), Messrs. Jas. O'Brien, S. Courtauld, H. Williams, Hugh Low, T. B. Haywood, F. Sander, and Dr. Masters. There were no specialties among the Orchids, but there was a very fine display of bloom considering the time of year.

Wilberforce Bryant, Esq., J.P., Stoke Park, Slough (gardener, Mr. Kemp), exhibited a large pot of *Oncidium ornithorhynchum*, a mass of bloom, but it was not one piece. A cultural commendation was awarded. Messrs. Pitcher & Manda, Hextable, Swanley, had a collection mainly composed of *Cypripediums* such as *Wallertianum*, *conchiferum*, *Harrisianum*, *Pitcherianum*, *Spicerianum*, *Ashburtoniæ*, *S. pendulum*, *atro-purpureum superbum*, and others. Messrs. F. Sander & Co., St. Albans, had a number of *Cypripediums*, including the beautiful *Spicerianum magnificum*, also *Phalaenopsis Lowi*, *Cattleya labiata*, *Calanthe orphanum* hybrid, *Zygopetalum rostratum*, *Cattleya Schofieldiana*, yellow variety; *Paphinia grandis*, *Oncidium Burbidgeanum*, and other good things (silver Banksian medal). Messrs. Hugh Low & Co., Clapton, had a small but very bright and varied group, in which *Vanda Kimballiana delicata*, *Cattleya superba splendens*, *Cypripedium Crossianum*, *Dendrobium formosum giganteum*, and *Cattleya speciosissima* were conspicuous (silver Banksian medal). Messrs. B. S. Williams & Son, Upper Holloway, had a bright collection in which *Dendrobium superbiens*, *Dendrobium Dearei*, *Odontoglossum grande*, *O. mirandum*, *Miltonia candida grandiflora*, and two fine pieces of *Cypripedium insignis* were very noteworthy (silver Flora medal). T. Statter, Esq., Stand Hall, Manchester (grower, Mr. Johnson), sent *Cattleya bicolor cœrulea*, which displayed a very peculiar colour contrast, the sepals and petals being greenish yellow and the lip pale mauve; also *Lælia elegans chelsensis*, and *Cattleya grandiosa splendens*. The latter, with its yellowish-green sepals and petals and pale lip deeply embossed with magenta, is very attractive. M. Wells, Esq., Broomfield, Sale (gardener, Mr. R. Hinde), sent *Cattleya Hardyana*, apparently a hybrid with *aurea* and *gigas* parentage. The apical portion of the lip are rich crimson, the side lobes nankeen yellow; the sepals and petals are rose with light veins, the former being much the deeper. C. K. Wild, Esq., Hampstead (gardener, Mr. Pallant) received a vote of thanks for *Stanhopea aurea* carrying nine flowers.

CERTIFICATES AND AWARDS.

Hymenanthera crassifolia (Messrs. Veitch & Sons).—This shrub is remarkable for the small white bead-like berries which stud the growths,

and give it a very beautiful appearance. The leaves, which are chiefly borne in tufts of three and four, are small, thick, and blunt. The sprays had been cut from the open (first-class certificate).

Rhododendron multicolor Neptune (Veitch & Sons).—A brilliant scarlet variety of great beauty. A standard about a foot high was shown, having seven clusters of bloom. There is room for many varieties of this type (first-class certificate).

Tacsonia Smytheana (Mr. W. Smythe).—A beautiful rich rose variety, very brilliant in colour, and doubtless very effective when expanded, but the flowers were not open (first-class certificate).

Chrysanthemum General Hawkes (Owen).—A Japanese with narrow, semi-tubular florets, maroon with silvery reverse; of good size and form (award of merit).

Chrysanthemum Lady Brooke (Owen).—A yellow Japanese with broad, flat florets, the lower cream, the upper ones bright yellow (award of merit).

Dracæna australis var. *rubra* (Elliott).—This differs from the type in the bronzy suffusion of the leaves. It has the same graceful appearance (first-class certificate).

Dahlia Mrs. Vagg (Rawlings).—A fine Show variety of splendid form and colour, being a rich rosy carmine (award of merit).

Apple King Harry (R.H.S.).—A tender, juicy, free bearing variety from the R.H.S.'s gardens at Chiswick (award of merit).

Apple Rivers' Collin (Rivers & Son).—A conical variety raised from American Mother, said to be a free bearer, and keeps to March (first-class certificate).

Grape White Gros Colman (Dicksons, Limited).—This variety has berries resembling the type in size and shape, but are more sweet and juicy (first-class certificate).

Grape Chasselas Vibert (R.H.S.).—An excellent cool greenhouse and outdoor Grape (award of merit).

Adams' Early Maize (Mr. Willard).—A useful Maize, the heads being of good flavour when cooked (award of merit).

Apple Seedling No. 2 (Mr. Ross).—A well coloured variety of fair quality (award of merit).

MR. DEWAR ON MICHAELMAS DAISIES.

The subject of the afternoon paper was Michaelmas Daisies, and the reader, Mr. D. Dewar, who has done much work amongst them during the last year or two and laboured manfully, together with his colleagues on the special Sub-Committee engaged on them at Chiswick, to secure order in a mixed and confused throng of species, hybrids, and varieties. The warm thanks of every lover of this beautiful and invaluable autumn flower are due to all of them. Mr. Dewar described the collection at Chiswick as the finest that existed in any one garden, the best cultivated forms having been gathered together and grown side by side with what were presumably wildings, this affording a good opportunity for observing the remarkable advance that had been made. As indicative of the confusion which has existed amongst those grown in British gardens, he alluded to the fact that they had greatly puzzled the late Dr. Asa Gray, notwithstanding that he had made the plants a life study. There were altogether about 250 species, and of this number the United States were the headquarters of 130 to 140. He pointed out the looseness with which the term "Michaelmas Daisy" is applied. *Erigerons*, for instance, distinguishable botanically in the number of ray florets, being so called, also giving other examples. The genus, he thought, requires thorough revision. It must be recognised how freely the plants hybridise, both in a wild state and under garden culture. The Sub-Committee were drawing up popular descriptions of the varieties, which would be published in due course.

Referring to the garden value of Michaelmas Daisies he thought that any hardy flowers such as these which tended to draw autumn and spring together were deserving of close attention. As decorative plants they were of great importance, and were extremely varied in habit, from the tall *novæ-angliæ* to the Dwarf *Stracheyi*. They had companions in the Golden Rods and Sunflowers. He recommended the employment of the dwarf forms, such as *alpinus*, *acris* and *Amellus* for bedding, and another use to which Michaelmas Daisies might be put was to plant them in association with *Rhododendrons*, which, though beautiful in spring, were afterwards bare. The plants well merited good and careful cultivation. They did best in a strong, deep, well-matured soil. He advised annual division, choosing the strong outer growths, and as all increased readily by cuttings, the young shoots might be inserted in spring, leaving the stock roots all the better for the thinning. They might also be raised from seed and an interesting course of crossing pursued. All the best forms had been thus obtained. He suggested the massing of some of the selected forms, such as *Cordifolius*, *Diana*, *W. Grant*, and *Lindleyanus*, and remarked that when grown in open spaces lateral branches were pushed almost to the ground. He then gave an interesting review of the genus, illustrating his remarks with examples of the different varieties. He pointed out the wide distribution of the forms and gave a few notes on the characteristics of some of the best. He thought that a garden name ought to be found to include the whole of the hybrids.

At the conclusion of the paper Mr. W. Marshall expressed a hope that English and not Latin names would be given to the varieties, and Dr. Masters alluded to the number of butterflies infesting the flowers in autumn, a point corroborated by another gentleman. A vote of thanks concluded the meeting.

PORTSMOUTH CHRYSANTHEMUM SHOW.

THIS great Show is fixed for November 2nd, 3rd, and 4th. A balance sheet of last season's Exhibition has been received, and shows a deficit, the first for eight years. Supporters of the Society are desired to do their utmost on its behalf, and if their efforts are supported by favourable weather there is little doubt that the lost ground will be more than regained.

CHRYSANTHEMUMS IN FINSBURY PARK.

THE twelfth annual display of Chrysanthemums in this park is now open to the public daily at ten o'clock. It will be at its best some two or three weeks hence.—J. MELVILLE.

CHRYSANTHEMUMS IN BATTERSEA PARK.

WILL you kindly announce in your next issue of the *Journal of Horticulture*, that the Exhibition of Chrysanthemums in Battersea Park will be open to the public on Saturday, the 15th October, in the frame ground, near the Albert Bridge entrance?—J. J. COPPIN, *Superintendent*.

NATIONAL CHRYSANTHEMUM SOCIETY.

THE autumn Exhibition of Chrysanthemums and other flowers will take place at the Royal Aquarium on Wednesday, Thursday, and Friday, October 12th, 13th, and 14th; and it is confidently expected the display of October-flowering Japanese varieties will be very fine. The Conference meeting arranged for Wednesday, October 12th, to consider the proposed enlargement of show boards for Japanese blooms, will take place in the Library of the Royal Aquarium at 7 P.M., Sir Edwin Saunders, President, in the chair, when it is expected that Messrs. C. E. Shea, R. Falconer Jameson, E. C. Jukes, and W. Herbert Fowler, among others, will read papers or take part in the discussion. It is hoped the members of the Society will attend the Conference.

CHRYSANTHEMUMS AT IMPNEY GARDENS.

FOR some years now—in fact, as long as Mr. R. Parker has had charge of them, these gardens have been celebrated for Chrysanthemums, and judging from the fine condition of the plants when I saw them a few days since they are not likely to lose any of their prestige during the coming tournaments. The plants are somewhat tall (a feature which is characteristic of all the collections I have recently seen in Worcestershire), very strong, having stout stems, well furnished with dark green thick leathery leaves almost to the base. The buds were mostly well developed and seemingly well timed, a point which specially marks the work of an experienced cultivator, such as is Mr. Parker.

At the time of my visit (September 25th) most of the plants were in light airy houses, such as would suit them admirably. About 600 plants are grown as standards for large blooms, ten or twelve plants each being grown of all the best recognised exhibition varieties. Half a dozen good plants of Richard Parker, the new golden yellow sport from Miss Haggas, now being sent out by Mr. N. Davis I noticed. Several plants each of the following new varieties, all of which Mr. Parker thinks are very promising, are being grown:—Edwin Beckett, Mrs. E. Beckett, Miss L. Cope, Le Verseux, W. Tricker, R. C. Kingston, W. K. Woodcock, J. S. Dibbin, President Harrison, and Miss M. Wightman. Most of these are likely to be seen upon the exhibition boards in November. A new American variety named Mrs. P. Rider, bronze and yellow, is just expanding its florets, and gives promise of being a valuable addition to our list of October-flowering varieties. It is very dwarf with good foliage, and produces brightly coloured large flowers. Mr. Parker thinks highly of it.

In addition to the 600 standards, about 100 plants are grown as large free bushes for decorative purposes. These average about 3 feet in height and 2 feet in diameter, are clothed with good foliage down to the pot, and appear to be capable of carrying twelve to twenty fine flowers each. One well known and popular variety (E. Molyneux) will this season be absent from Mr. Parker's stands. The reason of this is that shortly after the final potting an inexplicable disease broke out amongst the bushes and standards of this variety, causing the leaves to curl and the plants to assume a stunted starved appearance. The same thing has been noted in previous years by other gardeners and with other varieties, but it is generally limited to one variety in each case. It would be interesting to know if anyone can give a cause or cure for this.

PARKFIELD, WORCESTER.

At this fine place the gardens are well managed. The glass houses are very numerous, and perhaps the finest feature of them is the grand collection of Orchids. At present, however, my subject is only Chrysanthemums. Of these about 500 are grown as standards for large blooms, though not for exhibition.

The plants, though not so strong as those at Impney, are still very good, and will undoubtedly produce fine flowers. No particular attempt appears to have been made to time them so as to have early and late

flowering varieties in a special period, as has been done very successfully at Impney; consequently many are late, and the flowering season will thus be somewhat lengthened.

WITLEY COURT GARDENS.

Here Chrysanthemums are a great feature, about 800 plants being grown as standards with three blooms each. They are in most cases very tall but somewhat lacking in strength, the wood being less stout and the foliage smaller than of those at Impney. Many of the Japanese varieties have been allowed to go on to the terminal blooms, hence they will be rather late, smaller than if crown buds had been taken. The finest feature of this collection is about 100 plants of the "Queen" family. They are strong and will give good flowers.

ABBERLEY HALL.

On looking over the extensive and well kept gardens here one must come to the conclusion that failures are nowhere to be seen. That high culture prevails throughout is evident. Under such circumstances it would be strange if Chrysanthemums were only second rate. Although no exhibiting is done, the flowers being required only for home display, the plants approach more closely to the Impney standard of excellence than any others I saw in the county. About 500 are grown as standards and 200 as bushes. Anna Hartzhorn is now in flower, carrying fine deep blooms. There will be a grand display here during November.—W. K. WOODCOCK.

REVIEW OF BOOK.

A Manual of Chemical Technology. By RUDOLF VON WAGNER, translated and edited by WILLIAM CROOKES, F.R.S., from the 13th Enlarged German Edition as remodelled by Dr. Ferdinand Fischer London: J. & A. Churchill, 11, New Burlington Street.

THE publication of an English edition, revised by a competent authority, of Wagner's colossal work on chemical technology will be welcomed by students of all classes, and not the least by those who are animated by a laudable desire to acquire a sound basis of scientific knowledge. It is important in estimating the value of such a book as this to note that it is not one dealing with theories and general laws, but one abounding in practical information on a wide range of subjects, and therefore a real help to those who aspire to something more than a superficial acquaintance with the enormous field that is embraced in the term "chemical technology." It will be gathered that it is far from being limited in its scope to information on horticulture or botany, nevertheless its pages are a store from which few horticulturists who aim at a combination of scientific and practical knowledge can fail to draw with advantage. The character of a closely printed volume of 968 pages, embellished with nearly 600 engravings, cannot be conveyed with anything like full justice by a few references and extracts; nevertheless it will be well to refer to some points of special interest to horticulturists in order to give some idea of its general usefulness.

The work opens auspiciously with a consideration of fuel, and on the first page is a table showing the respective heat values of wood, peat, lignite, coal and anthracite. They are given in thermic units, and are as follows:—Wood, 4100; peat, 4500; lignite, 5700; coal, 8000; and anthracite, 8200. The last-named material has therefore a double advantage in its high heat value and non-smokeless character, and its use in gardens may be expected to extend. The information on thermometry that follows is of considerable interest. The first spirit thermometer (Moriani's) was, we learn, made in 1640, and it was Fahrenheit (1709) who first used mercury. Tables are given showing how the scales of Fahrenheit, Celsius (Centigrade), and Réaumur can be converted into each other. The recognised value of wood charcoal as a plant food will lend interest to the chapter on the manufacture of charcoal, although it is not with this object that the subject is so fully dealt with and so freely illustrated. The same remarks apply to heating.

A considerable amount of valuable information is scattered through the volume on the substances and preparations used as food for plants. Ammonia is dealt with at great length, and both inorganic and organic sources of it are pointed out. Of the latter coal is indicated as the most important. "In the production of coal gas and coke," we read, "it yields up its nitrogen as ammonia, which is obtained as gas liquor. The ammonia of the gas-water may be utilised in various ways. Where fuel is cheap, and crude ammonium sulphate, or crude sal-ammoniac, a marketable article, the gas-water may be at once neutralised by an acid, and the liquid thus obtained evaporated. This is done in a sal-ammoniac factory at Liverpool, where, during the colder season of the year, 300 cwt. weekly of this salt are prepared. Generally, however, the gas-water is submitted to a process of distillation, and the ammonia evolved converted into sulphate, as in Mallet's apparatus, or into sal-ammoniac, as in Rose's apparatus." The value of urine as a source of ammonia is pointed out, and it is also stated that "by the destructive distillation of animal substances, such as bones, hoofs of horses, refuse horn, skin, hides, decayed meat, &c., there is obtained a series of products, among which ammonium carbonate prevails. . . . The organic matter of these substances contains from 12 to 18 per cent. of nitrogen, the organic matter of bones contains 18 per cent. of nitrogen, and, as the organic matter amounts to about one-third the weight of the bones, these contain about 6 per cent. of nitrogen." Bones, therefore, may serve us as a source of nitrogen as well as a source of phosphorus. The methods of preparing sulphate of ammonia, one of our most valuable

fertilisers, are numerous. We learn that it is met with native in the mineral known as mascagnin on Vesuvius and Etna, in larger quantities in the boracic acid of Tuscany, and also in Boussingaultite, a mineral. The methods of preparation from the ammoniacal water of gas-works, lant (stale urine), the products of the dry distillation of bone, by the aid of sulphuric acid, or by double decomposition by means of gypsum or iron sulphate are described. It is pointed out that "ammonium sulphate is, industrially speaking, far the most important of the ammonia salts, because, besides being very largely used in artificial manure mixtures, and by itself for the same purpose, it is extensively employed in alum making, and is the starting point of the preparation of ammonium chloride, ammonium carbonate, liquid ammonia, and other similar products."

Phosphates, so valuable as sources of plant food, provide an interesting chapter. In superphosphate the phosphoric acid present in natural phosphates is rendered soluble by mixture with sulphuric acid. "The most important materials for the manufacture of superphosphate are the phosphorites. That occurring in large masses in Estremadura is nearly pure phosphate, but large quantities are met with in commerce which contain only 60 per cent., along with considerable quantities of silica and calcium chloride. Of less value are the staffelites from the value of the Lahn. The Canadian phosphorite contains :

Tricalcium phosphate	91.20
Calcium fluoride	7.60
Calcium chloride	0.78
Sand... ..	0.90
	100.48

Coprolites, the fossil manure of saurians, are found in the lias in Norfolk, Suffolk, Cambridgeshire, &c., in England, and near Helmstadt in Germany. A sample of Cambridge coprolites contained :

Moisture	0.12
Organic matter and combined water... ..	5.61
Silica	0.18
Carbon dioxide	6.50
Phosphoric acid... ..	30.21
Lime	49.01
Fluorine	3.08
Alkaline salts	5.29
	100.00

The materials are finely ground and mixed with the requisite quantity of sulphuric acid in pits provided with agitators. The mixture is rendered dry by the combination of the calcium sulphate with water, and is then broken up." The method of determining the soluble phosphoric acid as accepted at a meeting of agricultural chemists is given, with a considerable amount of other information ; also an illustration of the method by which fat is extracted from the bones by means of benzene. Guano, kainite, gypsum, nitrate of potash, and nitrate of soda are referred to at length ; nor will the information that is supplied on the preparation of potash from vegetable matter, supplemented as it is by tables showing the respective potash value of different woods, fail to receive earnest study.

Amongst the uses of sulphate of copper, to which the horticulturist turns with interest, the editor has omitted to allude to the large scale on which it is now utilised for the destruction of injurious fungi. Experiment proves that in combination with lime this valuable salt is a powerful antidote to the dreaded Potato disease, and there is every likelihood of the demand for it for this purpose developing largely.

Vines and wine making form a very interesting chapter, and not less so is that on starch and dextrine, introducing as it does our valuable friend the Potato. It may interest some readers to see the constitution of Potatoes as given :—

	Newly dug Potatoes.	Potatoes dried at 100°.
Water	75.1	—
Albumen	2.3	9.6
Fatty matter	0.2	0.8
Cellulose	0.4	1.7
Salts	1.0	4.1
Starch	21.0	83.8

Illustrations show the starch granules and the cells of the tuber, while the method of drying the starch is treated at length ; but into this and countless other features space will not permit us to enter.

The interest of the book to horticulturists is far from exhausted by these few brief references, and it may safely be said of this magnificent work that money devoted to its purchase is "an investment and not an expenditure."

ASTER DIPLOSTEPHIODES.

THIS fine and somewhat rare Aster, of which we give an engraving (fig. 43), was exhibited before the Floral Committee of the Royal Horticultural Society on July 26th by Wm. Marshall, Esq., of Bexley Heath, and a first-class certificate awarded for it. That it is so seldom

seen in gardens is no doubt to be accounted for by the difficulty experienced in its cultivation in some parts of the country. Described in 1836 by De Candolle in his "Prodromus" under the name of *Heterochaeta diplostephioides* and figured in the "Bot. Mag.," t. 6718, it would have been frequently met with could it be regarded as a true perennial in most gardens. This is not so, however, as in many places it proves to be only a biennial. It seems to be perennial at Bexley Heath, and at the Royal Gardens, Kew, and in at least one garden in the vicinity of Manchester. In several instances which have come within my notice it has not, however, proved so satisfactory, and has consequently been discarded. This appears to be a common occurrence with many plants

FIG. 43.—ASTER DIPLOSTEPHIODES.

from the Himalayas, of which *A. diplostephioides* is a native. Many of them are very fastidious in their ways, and while flourishing in some gardens are failures in others.

A. diplostephioides is seldom catalogued, and seeing it offered by a Cheshire firm a few years ago I sent for a plant, but was informed that the stock had been raised from seed, and that the plant had not proved hardy with them and could not be supplied. Seed was offered six or seven years ago by a well-known Ipswich seedsman, but this species has not proved satisfactory with him either. *Aster diplostephioides* grows from 16 to 24 inches in height and produces beautiful flowers of large size, in some cases nearly 4 inches in diameter. The ray florets are bright blue purple with a bronzy coloured zone and a blackish purple disc. It is to be hoped that its successful culture in some gardens may lead to it being more frequently seen.—S. ARNOTT.

INTERNATIONAL HORTICULTURAL EXHIBITION.

DINNER AND PRESENTATION TO MR. H. E. MILNER.

ON Thursday evening last a complimentary dinner was given to the Chairman of the Executive Committee of this Exhibition. About a hundred persons attended, including Mr. H. Percy Dodson (Chairman), Sir Charles Tupper (High Commissioner for Canada), Baron de Reuter, Baron G. de Reuter, Major Isaacs, Sir John Heron-Maxwell, Professor Stewart (Linnean Society), Col. Cody, Lieut. Dan Godfrey, Mr. Hays, Mr. Johnson (Treasurer), Mr. G. A. Loveday (Secretary); also, among horticulturists, Messrs. John Lee, W. Paul, T. Manning (representing Messrs. Veitch), W. Bull, A. Waterer, P. Barr, H. & A. Turner, H. Williams, F. Q. Lane, J. & H. Laing, W. Dreer, (Philadelphia), Owen Thomas, H. Herbst, A. F. Barron, R. Dean, W. Elphinstone, G. Wythes, and J. Wright.

In proposing the health of Mr. Milner, Mr. Dodson said the present Exhibition was got up in a period of about six weeks, the death of the Duke of Clarence having put a stop to the projected United Service Exhibition which was originally intended. All the work then devolved on Mr. Milner, who kindly offered his services. The undertaking had been most admirably managed, and during the whole time that the Horticultural Exhibition had been opened, thanks to that gentleman's good management, not a jar had occurred. On behalf of the whole Executive he had to express their grateful thanks to Mr. Milner, who in all respects had shown himself so thoroughly an English gentleman; and he asked his acceptance of a handsome silver salver, to which all the officials of the Exhibition had subscribed, as a token of respect.

Mr. Milner, in returning thanks, said the presentation was a total surprise to him, and he should regard it as a pleasant memento of the harmony and unity that had prevailed throughout the staff. All the officials of the Horticultural Exhibition had but one object in view, the success of the Exhibition, which had been gigantic. This was due to the great efforts of the Chairman, Directors, and members of the staff, who had ever been ready to help one another, from the highest to the lowest. The most distinguished scientific men and the noblest of the land had also lent their support, the Royal Family having privately visited the place no less than seven times. The desire of the Directors had been to encourage gardening and promote a love for it amongst all classes. The number of visitors up to the present time was nearly two millions. The Exhibition had been especially appreciated by ladies, and there had also been no accidents throughout the season. He felt deeply the compliment that had been paid him, and the remembrance of it would last through his whole life. Mr. Milner's excellent speech was much applauded.

The toast of "The Board of Directors and Officials of the Exhibition" was submitted by Sir Charles Tupper, who remarked that nothing had struck foreign visitors more than the fact that so remarkable a floral Exhibition could be brought together in this great smoky City. The people of England at large, as well as of London, were greatly indebted to Mr. Milner and his colleagues for all they had done in providing this beautiful Exhibition, and there would, unquestionably, be a widespread feeling of satisfaction if it were possible to continue it for another year. (Applause.) The toast was acknowledged by Mr. W. Hays and Mr. A. Johnson. Other toasts, which included "The Dinner Committee," proposed by Professor C. Stewart, and responded to by Mr. R. Dean; and "The Chairman," proposed by Sir J. Heron-Maxwell, and suitably acknowledged by Mr. Dodson, brought the proceedings of a pleasantly spent evening to a close.

LIST OF AWARDS TO SEASON EXHIBITORS.

THE following awards have been made to the permanent exhibitors at the International Horticultural Exhibition:—

Group A, class 1.—W. Richardson & Co., Darlington, gold medal; Mackenzie & Moncur, Edinburgh, silver-gilt medal; Compton and Fawkes, Chelmsford, silver medal; W. Duncan Tucker, Tottenham, silver medal; S. Deards & Co., Limited, Harlow, silver medal; E. Newton & Co., Hitchin, bronze medal for plant houses, vinerys, Peach houses, forcing houses, stoves, fruit rooms, frames, and pits. Class 2.—S. Deards & Co., Limited, Harlow, certificate; E. Newton & Co., Hitchin, certificate; Newton, Chambers & Co., Sheffield, certificate; E. Newton & Co., Hitchin, certificate for systems of glazing and ventilation. Class 3.—Thames Bank Iron Company, London, gold medal; Newton, Chambers & Co., London, silver-gilt medal; John Jeffreys, London, silver medal; W. Richardson & Co., Darlington, silver medal; John Watson, St. Albans, bronze medal for methods of heating, including hot-water boilers.

Group B, class 4.—Ransomes, Sims, & Jefferies, Limited, Ipswich, gold medal; A. Shanks & Co., London, silver medal for lawn mowers in hand or horse machines. Class 5.—Newton, Chambers & Co., Sheffield, silver medal for garden rollers. Class 6.—Merryweather & Sons, London, gold medal; Shand, Mason & Co., London, gold medal; J. H. Heathman and Co., London, silver medal; Wilson & Sons, Limited, London, silver medal; Sphincter Grip Armoured Hose Company, Limited, London, bronze medal for water barrows, syringes, pumps, and spray distributors. Class 8.—Joseph Davis & Co., London, silver medal; R. Springate & Co., London, bronze medal; Joseph Davis & Co., London, certificates for thermometers and barometers. Class 9.—Joseph Davis and Co., London, silver medal for rain and snow gauges.

Group C, class 10.—A. Maertons, London, silver medal; Gourrock Rope Co., Greenock, certificate; John Unite, London, certificate; Chas. Limare & Sons, Fecamp, certificate for garden tents.

Group D, class 15.—G. Micheli, Venice, silver medal for ornamental ironwork for conservatories and greenhouses. Class 16.—David Rowell and Co., London, gold medal; the Economic Fencing Co., London, silver medal for ornamental wirework, trellises, arches, apiaries, and aviaries. Class 17.—The Economic Fencing Co., London, silver medal for fences, gates, and tree guards.

Group E.—Corry & Co., London, bronze medal; W. Clibran & Son, Altrincham, bronze medal; Jos. Bentley, Barrow-on-Humber, bronze medal; Jos. Bentley, Barrow-on-Humber, bronze medal; James George, London, bronze medal; B. S. Williams, London, certificate; B. Hembrey and Co., London, certificate; G. Shearod & Co., London, certificate; J. Pinches, London, certificate; W. Clibran & Sons, Altrincham, certificate; Jos. Bentley, Barrow-on-Humber, certificates; James George, London, certificate; Charles Judson, London, certificate; W. Richardson & Co., Darlington, certificate for shadings, paints, labels, sticks, manures, silver sand, glass, weed-killers, soils, mats, insecticides, and fumigating materials.

Group F.—The Permanent Nitrate Co., London, silver medal; J. Waddell & Co., Greenwich, silver medal; W. Wood & Son, Wood Green, bronze medal; James George, London, certificate; the Stott Fertiliser and Insecticide Distribution Co. (Limited), London, certificate; W. Colchester, Ipswich, certificate; W. Wood & Son, Wood Green, certificates; G. W. Davis, London, certificate; the Horticultural Supply Co., London, certificate for Orchid and other peats, fuel for general horticultural purposes, fertilisers and artificial manures.

Group G, class 32.—Pulham & Son, London, silver medal; Dick Radclyffe & Co., London, silver medal for rockwork built in natural stone and artificial material. Class 31.—Dick Radclyffe & Co., London, silver medal; Charles Williams, Hammersmith, bronze medal for portable and permanent ferneries.

Group H., class 33.—R. Sankey & Son, Nottingham, silver medal; W. S. Iles, Camberwell, silver medal for garden pottery. Class 34.—F. Rosher & Co., London, gold medal; Pulham & Son, London, gold medal; Ernest Wahliss, London and Vienna, silver medal; Ardeshir and Byramji, London, silver medal; E. C. Fratelli Lapini, Florence, silver medal; Doulton & Co., London, silver medal for statuary, fountains, vases, edgings, &c.

Group I.—W. Barron & Son, Barrowash, silver medal; Jesse Martin, Great Totham, silver medal for tree transplanting machines and tree tubs.

Group K.—Ransomes, Sims & Jefferies (Limited), Ipswich, certificate; J. Kelly, London, certificate; J. Watson, St. Albans, certificate; P. Mayfarth & Co., Frankfurt, certificate; The Stott Fertiliser and Insecticide Distribution Co. (Limited), London, certificate for new or patent inventions among garden requisites.

Group L.—L. Farina & Co., London, silver medal; Madame Goffton Salmond, Norwood, silver medal; E. Bombois, London, certificate; Chas. Williams, Hammersmith, certificate for miscellaneous decorative requisites, such as bouquet holders, papers, tubes, &c.

Group M, class 43.—P. Mayfarth & Co., Frankfurt, silver medal for pumps and methods of irrigation. Class 41.—Gower, Dodson & Co., London, agents to Bulgarian Government, gold medal for perfumes.

Group N, class 44.—Jarman & Co, Chard, Somerset, gold medal for models of produce from seeds provided by the exhibitor.

Group O, classes 52 to 55.—Australian Irrigation Colonies, London, silver medal for the general improvement of grounds. Class 52.—Reid and Bornemann, Sydenham, silver medal for a design for the laying out of a typical estate of 100 acres. Class 53.—Van Hulle, Ghent, silver medal; T. Mawson, Windermere, silver medal for designs for the improvement of grounds attached to private residences.

Group P, class 56.—Geo. Cadell, silver medal, for an essay on the progress of gardening since 1886 to date of the last International Horticultural Exhibition.

Sundries.—B. S. Williams & Son, Upper Holloway, gold medal; Compton & Fawkes, Chelmsford, silver medal; J. E. & S. Spencer, London, gold medal.

FRUIT AND POTATO EXHIBITION.—OCTOBER 5TH, 6TH, AND 7TH.

THE Exhibition that opened at Earl's Court on the 5th inst. is in many respects one of the most important of the series held there during the present season. The bringing together of a representative collection of hardy fruit is much in itself, but in alliance with a similar Show of Potatoes its interest and value are largely increased. With the little time at our disposal for dealing with the collective display, general remarks must be brief. It should be noted, however, that alike in magnitude and quality the twin Exhibition is a magnificent one, and it is not easy to say which portion of it possesses the greater interest. Apples are magnificent, there being an enormous number of dishes of very high quality, and Potatoes are also splendid.

FRUIT AND VEGETABLES.

Class 1 is for a collection of Apples, kitchen and dessert, six fruits of each variety; and Messrs Bunyard & Co. win with a magnificent contribution, comprising 100 dishes. The examples of Gascoigne's Seedling, Golden Spire, Warner's King, Lord Derby, Bismarck, Norfolk Dumpling, Ecklinville, Grenadier, and Lady Sudeley are superb. The second prize goes to the English Fruit and Rose Company for a similar

number of dishes, but the fruit is hardly so heavy as that from Maidstone. Mr. J. Scott, Crewkerne, is third.

For a collection of Pears, six fruits of each, Mr. Becker, 13, Beresford Street, Jersey, is first with forty-eight very fine dishes of leading varieties. Mr. G. Woodward, Barham Court Gardens, Teston, Maidstone, is second; and Mr. A. J. Thomas, Sittingbourne, third.

Mr. Woodward shows some grand fruit in the amateurs' class for fifty dishes of Apples, and is an easy first. The Queen, Cox's Pomona, Queen Caroline, Small's Admirable, Washington, Stone's Nonesuch, Emperor Alexander, Warner's King, and others are splendid. Mr. Turton, Reading, is second, with smaller but clean well-coloured fruit; and Mr. Goldsmith, gardener to Sir E. Loder, Horsham, third. Mr. J. Mackenzie, Lintern Park, Maidstone, wins with twenty-four dishes, most of the fruit being large, clean, and full of colour. Mr. Smith, Loddington, Maidstone, is second, and Mr. Turton third, both with very fine dishes. Mr. Woodward has another magnificent exhibit in the class for twelve dishes, all being heavy and rich; Bismarck, Washington, The Queen, and Stone's are grand dishes. Mr. Austin Killick, Maidstone, is second, with smaller but nevertheless fine dishes; and Mr. G. Chambers, Maidstone, third. His samples of Pomona Apple are very noteworthy. Pears, twelve dishes, are best shown by Mr. Goldsmith, who wins with a heavy collection. Mr. Offer, Crawley, is second; and Mr. Nicholson, Chingford, third. Mr. Smith, gardener to Lady Frances Fletcher, Yalding, wins with six dishes; Messrs. C. West, Landford, Salisbury, and J. G. Dean, gardener to L. Leveson Gower, Esq., being second and third.

The collections of vegetables bring out some really splendid produce. With a trophy arranged for effect Mr. Pope, Newbury, is first with a magnificent display, his Carrots, Beet, Leeks, Potatoes, Celery, and Onions being very fine. Mr. Gibson, Carshalton, is second, also with a very fine display. Mr. Wilkins, gardener to Lady Theodore Guest, Henstridge, is first with a collection of twelve dishes, his Lyon Leeks, Solid White Celery, and New Intermediate Carrot are very fine. Mr. Lye, gardener to W. H. Kingsmill, Esq., Newbury, is a good second with many grand dishes. Mr. Friend, gardener to the Hon. P. Glyn, Rooknest, Godstone, is third.

Miscellaneous displays of fruit are one of the best features of the Show. Messrs. J. Veitch & Sons have a grand collection of Apples, Pears and Plums, comprising 300 dishes (gold medal). Mr. H. Becker, Jersey, exhibits some enormous Pears, Doyenné Boussoch, weighing 24 ozs., Buerré de l'Assomption 21, Duchesse d'Angoulême 24, Grosse Calebasse 22, Belle de Jersey 23, Catillac 30, King Edward 19, Doyenné du Comice and Conseiller de la Cour 18 each (silver medal). Messrs. H. Lane & Sons stage about ninety dishes of Apples and a collection of Filberts (silver medal). Messrs. Jarman & Co. have about seventy dishes of Apples, and fine specimens of Somerset Hero and other Onions (silver medal). Mr. Meads, gardener to G. Loveday, Esq., has a good basket of Pitmaston Duchess Pear. Messrs. S. Spooner & Sons contribute about seventy dishes of Apples and Pears, chiefly the former. Messrs. T. Rivers & Son have staged a number of orchard house trees, also some splendid dishes of fruit (gold medal). Messrs. C. Lee & Sons, Hammersmith, have nearly 100 dishes and baskets, mainly Apples large and well coloured. Mr. W. Taylor, Hampton, has forty dishes of Apples. Mr. W. A. Trotter, gardener to F. Ricardo, Esq., Bromesborough Place, Ledbury, exhibits a box of evaporated fruit, also Peas and French Beans (silver medal). Mr. G. Reynolds, Gunnersbury Park, has a splendid collection of Melons. Mr. Bythway has a few dishes of Apples.

Mr. W. Iceton has baskets of market Grapes. A splendid collection of Apples and Pears, comprising about 150 baskets and dishes comes from Messrs. Cheal & Son, the first being of splendid quality (silver-gilt medal). Mr. Miller, gardener to Lord Foley, Esher, has a small collection, and Mr. Watkins contributes cider and ornamental Apples. Mr. Woodward receives a silver-gilt medal for some splendid Peaches and Nectarines grown in the open. Mr. S. T. Wright, gardener to C. Lee Campbell, Esq., has nine bunches of Grapes (silver medal). Messrs. Bunyard & Co. have a splendid display of fruit outside the annexe that must not be missed (silver-gilt medal).

POTATOES.

In Classes 1 and 2 the prizes are offered by Messrs. Sutton & Sons, Reading. The first is for twelve dishes of Potatoes, distinct varieties, nine tubers of each. There are ten entries, and the competition is very keen. The leading prize, however, goes to Mr. J. H. Ridgewell, Cambridge, for splendid examples of Beauty of Hebron, Fidler's Reading Giant, Edgecote Purple, Pink Perfection (very fine), The Dean, Satisfaction, Mr. Bresee, Perfect Peachblow, Lord Tennyson, Snowdrop, Queen of the Valley, and Come to Stay. Mr. W. Pope, Newbury, is second; Mr. A. V. Cross, Banbury, third; Mr. W. Kerr, Dargavel, Dumfries, fourth; and Mr. G. Galt, Oxford, fifth. For nine dishes, distinct varieties, Mr. James Simkins, Shillington, Hitchin, is first; Mr. A. Coombes, Dudley, second; Mr. R. Lye, gardener to W. H. Kingswell, Esq., Newbury, third; Mr. C. J. Waite, Esher, fourth; and Mr. A. V. Cross, fifth.

For six dishes of distinct varieties Mr. J. Simkins is first, showing splendid tubers of Reading Giant, Reading Russet, Sutton's Seedling, Abundance, Windsor Castle, and Satisfaction. A silver medal was awarded for Reading Giant as being the best dish of Potatoes exhibited in the competing classes. Mr. W. Pope second, with smaller but even tubers; Mr. J. H. Ridgewell third; Mr. R. Lye fourth; and Mr. A. Chopping, Milton, Sittingbourne, fifth. Mr. G. Galt secures the first

prize for three splendid dishes of London Hero, Abundance, and Satisfaction. Mr. A. Chopping second; Mr. R. Lye third; and Mr. J. H. Ridgewell fourth.

For three dishes of coloured round Potatoes, Mr. J. H. Ridgewell is placed first for grand specimens of Reading Russet, Vicar of Laleham, and Pink Perfection. Mr. A. V. Cross, secures a second position. Mr. J. Friend, third; and Mr. R. Lye fourth. White kidney varieties are well shown. Mr. J. H. Ridgewell is first for three dishes of distinct varieties, nine tubers each, showing Snowdrop, Reading Giant, and Fidler's Purity in grand condition. Mr. James Lye, Market Lavington, is second, and Mr. Chopping third. Mr. J. H. Ridgewell is first for coloured kidneys.

Some splendid tubers of white round varieties are staged. In the class for one dish Mr. T. Wilkins, is first, showing magnificent samples of London Hero; Mr. J. Simkins second with Windsor Castle, and Mr. J. H. Ridgewell third. There are twenty-four entries in this class. Mr. J. Simkins has the best dish of any coloured round variety. For the single best dish of any white kidney Potato, nine tubers, Mr. J. H. Ridgewell was first with beautiful samples of Snowdrop; Mr. E. Chopping second, Mr. W. Pope third, and Mr. G. Wheeler, Newbury, fourth. Mr. T. Tooley, 22, Albert Street, Banbury, had the best dish of any coloured kidney, showing Mr. Bresee. Mr. W. Pope was a close second with Edgecote Purple, Mr. T. Wilkins third, and Mr. Ridgewell fourth.

In the class for six dishes of Potatoes introduced into commerce since January, 1886, prizes offered by Messrs. Sutton & Sons, Mr. J. Simkins is awarded first honours. Mr. J. Ridgewell second; Mr. J. Lye, third; Mr. A. V. Cross, fourth; and Mr. R. Lye, fifth. For three dishes of distinct varieties, Mr. J. H. Ridgewell is first; Mr. T. Tooley is second; and Mr. E. G. Wiles, Oxford, third.

Medals and certificates are awarded for various seedling Potatoes not in commerce. In the class for a single dish of seedling white round, Mr. J. Lye secures a bronze medal for a variety named Advance, a cross between Reading Russet and Schoolmaster. Mr. C. Ross gains a first-class certificate for Recruit, a clean round tuber, and Mr. E. Wiles a similar honour for Oxford Surprise (Chancellor x Sutton's Abundance). Mr. T. Laxton, Bedford, is also awarded a certificate for Murphy (Scotch Champion x Reading Hero), a medium-sized tuber of good shape. For seedlings of coloured round varieties, Mr. W. Kerr, Dumfries, gains a certificate for a seedling from Abundance. Similar honours go to Mr. Wiles for Pink-eyed Perfection (Abundance x Reading Russet), and to Mr. H. Fletcher, Annesly, Notts, for Lillic Langtry, a seedling from Lord Tennyson. For seedlings of any white kidney variety, three certificates are awarded as follows:—Mr. E. Wiles for Oxford Geart; Mr. C. W. Howard, Canterbury, for Lord Wolseley (Woodstock Kidney x Edgecote Seedling); and Mr. C. Ross for Rising Star, an even-shaped kind. Mr. J. H. Ridgewell secures a bronze medal for New International, a midseason variety. Mr. E. Chopping is awarded a similar honour for Lord Raglan (Woodstock Kidney x Blanchard). Mr. W. Kerr has a certificate granted for a seedling from Abundance. Messrs. Laing & Sons, Forest Hill, are awarded a first-class certificate for Mammoth Red Celery, a magnificent variety.

Messrs. Sutton & Sons, Reading, stage a large number of dishes of magnificent seedling and other Potatoes, possibly one of the finest collections ever brought together. The tubers were remarkable for their even size and bright, clean appearance. Messrs. Sutton also have a large number of miscellaneous vegetables, including Carrots, Marrows, Kohl Rabi, Parsnip, Beet, Onions, Leek, and Savoy. A gold medal was awarded for this fine exhibit. Messrs. W. W. Johnson & Sons, Boston, stage a large collection of well grown Potatoes (bronze medal), and Mr. C. Fidler, Reading, gains a silver medal for a collection of fine tubers. Messrs. Davidson & Sons, Leicester, secure a bronze medal; and Mr. W. Kerr, Dumfries, a silver medal for Potatoes. A silver-gilt medal goes to Mr. E. Chopping for a similar exhibit.

MISCELLANEOUS.

Messrs. W. Paul & Son, Waltham Cross, half fill the annexe near the main entrance with a splendid collection of shrubs and Conifers in pots, and Messrs. Cheal & Son have a stand of hardy flowers and fruit. Mr. H. Wrede, Luneberg, Germany, has a collection of Pansies (silver medal). Messrs. B. S. Williams & Son are represented by a display of Crotons and other foliage plants. Mr. Geo. Wythes has a group of early Chrysanthemums. Messrs. J. Laing & Sons have a beautiful group of Begonias well displayed (gold medal). Mr. Chas. Turner stages numerous boxes of good autumn flowers (silver medal), and Mr. C. Holder a mixed group (bronze medal). Messrs. E. D. Shuttleworth & Co. have a group of Palms and foliage plants (silver-gilt medal). Messrs. W. Barron and Co. stage sprays of ornamental trees and shrubs. Messrs. Barr and Son exhibit their Anti-blight and a beautiful assortment of hardy flowers. Prizes for Sunflowers and Michaelmas Daisies go to Messrs. Barr & Son, Mr. Davis, and Mr. G. H. Sage. Mr. Chard receives a silver medal for table decorations.

Mr. H. Deveriel, Banbury, is awarded a silver-gilt medal for a splendid collection of Onions, Leeks, and Carrots; and a similar award goes to Vilmorin, Andrieux & Co., Paris, for Celery and Endive. Mr. Ryder, Orpington, Kent, stages a collection of Tomatoes (silver medal), and Messrs. R. Veitch & Son, Exeter, show a basket of Prodigious Potato, a remarkably heavy cropper of first-rate quality, judging from cooked samples also exhibited.

FRUIT FORCING.

Vines.—*Early Forced Vines in Pots.*—To have ripe Grapes in March the Vines should be started not later than the early part of November. The Vines must be selected from those which have been started early in the year as cut-backs, and grown through the spring and summer in abundance of light so as to secure sturdy, thoroughly solidified canes, with plump buds, the wood being brown and hard. Strong canes are not necessarily the best for fruiting in pots, certainly not for early forcing, but they must be stout, short-jointed, and well matured in the wood, and the eyes must not be pointed or flat, but rounded and rather prominent. The varieties also should consist of the best forcers. White Frontignan never fails to show plenty of fruit on well grown canes, and it sets, swells, and perfects earlier than any other, and possesses a rich Muscat flavour. Foster's Seedling can hardly be grown at all without fruiting freely. It forces first-rate, ripens about the same time as the Black Hamburgh, and has a sweet, juicy, but not any Muscadine flavour. Black Hamburgh answers well for very early forcing, and, unless over-burdened with fruit and hungred or over-fed, finishes well. Madresfield Court produces fruit freely on well-matured canes, its oval berries show to advantage beside Black Hamburgh, and the flavour of the ripe Grape is very agreeable, sometimes having a slight trace of Muscat. Those four varieties we have found thoroughly reliable, and under good management they will produce Grapes fit for the table in March. It is no use, however, attempting to force indifferent canes, and the best must have a house that will catch every ray of light, as a lean-to or three-quarter span facing south, and plenty of hot water pipes, with due provision for ventilation. It is also a great aid in forcing to keep the glass free from ice. This can be effected by fixing a 1½ inch wrought iron galvanised pipe along the bottom of the rafters about 6 inches from the head of the front lights, and another at a similar distance lower down the roof than the opening of the top lights, the pipes being taking longitudinally of the house. The heat given off by these pipes is advantageous for ventilation purposes and to secure a more even temperature. The Vines being in their fruiting pots, say 12-inch, will only need the drainage seen to, and if defective rectified, but if they are in small pots they may be shifted into larger, yet only so increased in size as to admit of about an inch of soil all round the ball, which should only be loosened a little at the sides, and the fresh soil must be rammed as compact as the ball. Turfy loam, free from wireworm, torn up to a convenient size, with a pint of steamed bone meal to every bushel and a similar proportion of wood ashes form a suitable compost. The advertised fertilisers are excellent, and may be used instead of the above substances, following the instructions supplied with each. It is better not to be under the necessity of potting the Vines, yet it may be done without prejudice to the forcing. Provided the soil is moist enough, so as to keep the roots healthy, no water should be given, and the Vines are best kept no more than just damp at the roots till they start into growth.

Where there is a bed of about 3 feet depth and 4 feet width, 9-inch pedestals of loose bricks may be erected at 2½ feet to 3 feet distance apart and in the centre of the bed, and carried up so high that when the pots are placed upon them their rims will be slightly higher than the pit edge. The pit being filled with Oak or Beech leaves a gentle warmth will be afforded the Vines, and a genial moisture pervades the house, the bottom heat accelerating root formation, the transmission of steady supplies of nourishment, and this, with the congenial condition of the atmosphere, induces the canes to break well and to progress satisfactorily. The roots also pass from the pots into the leaves, deriving support—mainly nitrogenic and potassic elements—beneficial to the growth of the Vines and the production of Grapes. The temperature at the roots must not exceed 65° to 70° at the start, raising it by adding fresh material to 75° when the Vines are fairly started. The Vines should be placed in position by the middle of this month, and have a temperature of 50°, which will promote slight activity in the sap, and on November 1st the temperature must be kept at 50° to 55° by artificial means until the buds swell, then gradually increase it to 60° to 65° when they are breaking. The canes should be depressed to a horizontal position to secure their breaking regularly, and the house and canes will need damping every morning and afternoon, but not before the Vines are started.

Early-forced Planted-out Vines.—These may be forced to ripen the Grapes in March or early in April. It is, however, one of the worst practices in forcing Vines, and is little followed now, as the thick-skinned Grapes meet most requirements up to May, and where thin-skinned Grapes are desired in March and April it is better to provide a supply by growing Vines in pots. Nevertheless, pot-vine Grapes are not equal to those produced by Vines well established in inside borders, yet the Vines wear out quickly, as the consecutive early forcing is a great strain on their energies through the growth having to be made at the dulllest, and the rest taken at the hottest period of the year. It is extremely difficult to preserve the foliage in health after the Grapes are ripe, for red spider is seldom or never disassociated with early-forced Vines, and, unless the laterals are encouraged, so as to keep the roots active and afford an outlet

for the sap, the buds that are intended to furnish the succeeding season's crop of Grapes would probably be forced into growth in late summer, as we have seen them doing so in September. The beginning of December is quite early enough to start permanently planted-out Vines, and they will then ripen Grapes of the highest excellence in May. There is nothing gained by hard forcing except thin foliage to be scorched by powerful sun or made brown by red spider, and very moderate Grapes. Very early Grapes, however, generally finish well, except when the Vines are overcropped, and are free, as a rule, from shanking, even when the roots of the Vines are in an outside border 20° or more less in temperature than the mean of the atmosphere of the house, the micro-organism that produces this disease not being present at the dead season of the year.

Where there is no provision for growing pot Vines, which we strongly advise, and Grapes fit for table must be had in late March or early April, the Vines should be started not later than the middle of November, and we prefer to commence in earnest a fortnight earlier. Up to that time the house should be kept cool and dry, and the outside border, if any (and it is a grave mistake in early forcing), should be protected from autumn rains by covering it before the ground is chilled by continued wet and cold. We use a good covering of dry leaves with a little litter on the top to prevent them blowing about, 9 inches thickness being effectual against frost, and if tarpaulin is employed over all in case of heavy rains or snow nothing further is required. If the border is allowed to become moistened through by the autumn rains before being covered, no water will be needed there until the Grapes are perfected. Fermenting materials on outside borders are often more injurious than beneficial, because the heat is not regularly maintained, often being allowed to become cold and wet just at the time when the Vines need active roots to supply nourishment to the foliage and fruit. But they are very useful for placing inside the house to generate and maintain a genial condition of the atmosphere, and are economical, as the warmth and moisture given out lessen recourse to so much fire heat or sprinkling from the syringe. The fermenting materials should not be used until the house is closed, but they will need to be thrown into a heap a week or ten days previously, turned, and moistened if necessary. Three parts Beech, Oak, or Spanish Chestnut leaves to one of stable litter give a more suitable warmth, and a more congenial and ammonia-charged atmosphere than all manure. Mix well together when thrown into the heap, sprinkle water if dry, turn in four days to a week, throwing outside to inside, damp again if necessary, and when warmed through the material is fit for placing in the house.

Late Muscats.—The Grapes will now be thoroughly ripe, but they will improve in colour and maturity up to about December, and the foliage will be retained some time longer where the border is kept properly moist by watering as required in the early part of fine days. Muscat of Alexandria and Canon Hall become quite whitish, yellow, and sere at the edges of the leaves long in advance of the foliage falling, whilst the veins and footstalks are quite green and capable of assimilating some food which goes to plump and perfect the buds and is stored in the wood. Retain the leaves, therefore, as long as possible, and a moist condition of the soil will not injure the Grapes provided the atmosphere is not stagnant and does not become saturated with moisture for want of increased ventilation on fine mornings to dissipate it instead of allowing it to be condensed on the Grapes. A temperature of 50° should be maintained at night and 5° more by day, with sufficient ventilation so as to insure a circulation of air, and it should be admitted freely on all favourable occasions by day. If the Grapes are not well finished they should have a night temperature of about 60° to 65°, 70° to 75° by day, and 10° to 15° rise from sun heat, all with air, and the soil must be kept properly moist; but it is difficult to get finish into Grapes by a forcing temperature in autumn.

Late Grapes.—The thick-skinned varieties will be thoroughly ripe if they were started in good time, and have been assisted through the late spring and summer months with artificial heat. When the Vines, however, are started in April, and not accelerated in growth and for the perfecting of the Grapes, the latter will not be ripe, and they probably never will ripen, as we have found a forcing temperature after October comes in to have a very indifferent effect upon the fruit in ripening. If there is any deficiency of finish the chances are that it will never be improved; but in that case the temperature should be kept at 60° to 65° at night, 70° to 75° by day, 80° to 85° from sun heat, continuing this until the Grapes are ripe—at least, until the wood is brown and hard, which is essential to the production of fruit in the ensuing season. Only thoroughly ripe Grapes can be expected to keep satisfactorily, and in that case, the wood also thoroughly matured, all spray or laterals may be removed down to the main buds, ventilating freely on all favourable occasions, and fire heat will only be necessary to prevent the temperature falling below 50°. To prevent dust settling upon the berries, raking or sweeping must not be practised. If the border is covered with clean dry mats it will to some extent prevent evaporation, assist in keeping the atmosphere dry, and prevent the soil cracking. Ventilation, however, is the best antidote against the Grapes damping, and there must be a certain amount of atmospheric moisture, with a not very dry condition at the roots, or the Grapes will shrivel. Outside borders may be covered with glass lights to throw off heavy rains, or a good covering of bracken or straw is very serviceable, but many have to be content with a few inches thickness of leaves or litter.

Young Vines.—There is little gained by keeping Vines that have a tendency to keep on growing in an atmosphere favourable thereto, and lateral growth after this serves only to accelerate the evil—immaturity

of the wood. Check growth, therefore, by gradually removing the laterals, so as not to start the main buds, and facilitate the ripening of the wood by a high temperature and dry atmosphere by day, say 70° to 75°, with 10° to 15° rise from sun heat, with moderate ventilation, shutting off the heat and keeping the ventilators open at night, except when frost prevails.

PLANT HOUSES.

Chrysanthemums.—These should be housed without delay, or injury from frost may result. After the plants are placed under glass syringe them freely, or their foliage will be liable to suffer by the dry atmosphere of the structure. Slugs are frequently carried into the houses with these plants. It is a good plan to look over the pots carefully with a light several nights in succession to remove any that show themselves. Slugs may destroy some of the best blooms, while they prey injuriously upon the cuttings at a later date. If aphides are prevalent fumigate the house with tobacco smoke. They are much easier destroyed at the present time than when the plants are in full bloom. Once the blooms are infested with these pests they are soon spoiled, and rendered useless for any purpose. Late kinds that are grown for cutting purposes only may be kept outside; but they should be placed where slight protection can be given them in case of frost. If these plants are to keep their foliage healthy the roots must be kept at work near the surface, and then those grown for large blooms will develop flowers of the best quality. This can be accomplished by applying stimulants in a weak state, and artificial manure in small quantities to the surface soil occasionally. Flat blooms that are both void of colour and substance are frequently the result of overfeeding, which destroys the roots; unless the latter are thoroughly active until the last well-finished blooms cannot be expected. Earwigs are numerous this year, and they must be carefully watched for, as they soon devour the petals and destroy the blooms. Give abundance of air to plants placed under glass, so that the flower buds are not unduly hurried forward. It is also the best means of preventing damping in those expanding.

Calceolarias.—The earliest of these may be placed into 3 or 4 inch pots, according to their size. Grow these plants in a cold frame, but watch for slugs, which are particularly fond of them. Later plants may be pricked into pans and boxes according to the quantity grown. These may now have a light airy frame, and will do better than if kept in one with a northern aspect.

Cinerarias.—The earliest batch of these will be coming into flower and will be useful in the conservatory. Later batches that need more root room should be repotted at once. It is useless to repot those that are already showing their flower stems. Those for flowering in spring should be well cared for, because they are invaluable when the majority of bulbous plants are over. These plants will do for some time in cold frames. Give them abundance of air daily, and leave a little on the frames all night when mild. The watering of these plants should now be done in the morning. To those in their flowering pots that are well filled with roots weak stimulants may be given. Soot water in a clear state is very beneficial to them. Watch for aphides and destroy them directly they make their appearance.

Lilium Harrisii.—This is a useful decorative plant when in bloom, and should be grown in quantity. Medium sized bulbs should be placed in 6-inch pots that are well drained. The compost should consist of fibry loam three parts, the remaining part being composed of leaf mould and sand; to this may be added one-seventh of decayed manure. In potting the bulbs must be just covered. If the soil is moderately moist no water should be given. Stand the pots in a cold frame and fill the spaces between them with cocoa-nut fibre refuse, covering the surface with about 2 inches of the same material. Failing this fine ashes will answer the same purpose. When subjected to this treatment evaporation is prevented and the bulbs soon commence to root and grow. As soon as they show through the plunging material remove the plants to the greenhouse and apply water. If grown in quantity a low cool airy house will suit them well, or they may be placed on shelves moderately close to the glass. From one batch of plants a long succession of bloom may be obtained if proper treatment is given.

Callas.—If these are still in the open they should be lifted without delay, well watered, and stood behind a north wall until root action has commenced, when place in their winter quarters. Solanums, Bouvardias, Salvias, and other plants that are outside should be lifted and treated in the same way until they are established. If there is any appearance of frost while the plants are outside protect them by covering with mats.

Ivy-leaved Pelargoniums.—Plants that have been well ripened will, if placed under glass where a night temperature of 55° to 60° can be maintained, soon come into flower. If the plants have been standing outside they should have cool airy treatment for a week or two, and then gradually kept close. Those well ripened under glass and recently potted will in gentle warmth soon come into flower. Those for spring flowering in 5-inch pots may be pinched and placed on a shelf where the temperature will not fall below 45° during the next three months.

Zonal Pelargoniums.—All plants grown for autumn and winter flowering should be under cover. Heavy rains and dull sunless weather is very liable to start them into a soft growth, and if this takes place the plants will not flower satisfactorily. Those placed in a suitable house if gradually kept close and finally subjected to a temperature of 55° to 60° will be in full bloom during the early part of November, a time when they are specially useful. Those not needed so early may have the protection of cold frames for a time. Give them abundance of air when favourable, throw off the lights during fine days, but protect them from frost and heavy rains.

French and Fancy Pelargoniums.—For early flowering these plants are best in 5-inch pots. For this purpose cuttings are rooted early, placed into 3-inch pots, and the point pinched out, or, better still, taken out when the cuttings are inserted. If this is done the plants start into growth with three or four shoots, and are established in 3-inch pots. From this size they should be placed into 5-inch pots, using a compost of loam and sand, with one-seventh of decayed manure. The soil must be pressed firm into the pots to induce a slow sturdy growth. The plants should not be pinched again, but when potted stood on a shelf where the temperature during the winter will average about 40°. If the batch prepared for this purpose is too large pinch the remainder, give them the same treatment, and finally place them into 7-inch pots. Young stock are preferable to old plants. The earliest of these should be given similar treatment to that advised for the young stock; the second batch ought to be shook out and repotted in smaller pots. Keep these close for a few days until they have commenced to root, when place on a shelf in any cool house. Cuttings that have been dibbled in outside and are rooted may be potted and placed on a shelf in a cool house. A late batch of these plants are often as important as an early one.

Heliotropes.—Plants that have been grown outside as standards and bushes may now be placed into gentle warmth, when they will start into growth and soon be in full bloom. Those for spring flowering may be pinched and placed into 3-inch pots, and stood on a shelf where the temperature will range from 45° to 50°.

Fuchsias.—Cuttings that are just rooted may be potted singly into 3-inch pots. Stand these on a shelf close to the glass, where the temperature does not fall below 50°, until they are established, finally placing them where they can be kept at 45°. In this temperature they will grow slowly during the winter, and make excellent decorative plants early in the season.

APIARIAN NOTES.

BEES EXPELLING DRONES.

"J. H. M." would like our opinion about bees killing their drones tardily. It is not easy to diagnose the actual state of any hive by the killing of its drones without seeing it at work, and the manner the bees kill them. It is generally supposed when bees kill their drones that the queen is all right, and laying fertilised eggs, but this cannot be depended upon. The youthful bees in a normal hive as a rule begin to expel the drones shortly after they creep out the cell, and after they are strong enough for that work. This refers to the first-hatched bees of a young queen. Bees have also the habit of treating drones roughly unto death when they appear anxious to have their virgin queen mated, and this sometimes continues throughout the season until all the drones are killed, while the queen still remains in her virgin state. We had numerous instances this year. Our correspondent should examine the combs, and make sure the queen is a fertilised one; a little feeding will cause her to lay. Drone brood is known by the ruggedness of the cells, and the prominent convex coverings of them; while the worker brood is flat and even, or only a very little raised. Possibly the existing queen may be a drone breeder.

PUNIC BEES.

Continuing my notes from page 294, I come to Punics. They do not get into a frenzied state, like most other varieties do when in transit, so are valuable where they have to be taken long distances to the Heather. If spared till another year I will do my utmost to have one or more pure stocks tested for honey gathering. Crosses are superior, and judging from the way pure ones have worked in 1891 and 1892 at the Heather I am favourably impressed with them, and, as one of my pure queens is still living, hope they will survive the coming winter. One second cross by Carniolan drones are beauties; they cannot be detected from pure Carniolans in colour, but for smartness I have witnessed none to equal them, the untoward season also frustrating all attempts at proving the progeny of this year's mated queens.

THE TEMPER OF PUNICS.

The temper of Punic bees is not so mild as Carniolans, but is milder than all the other varieties I have had to do with. They are not nearly so fierce as the original British bee. The last-named variety attacks people at a great distance from their hives, which the Punics do not. I have never been attacked by a Punic bee further than 10 yards or so, and they do not follow the victim like Italian nor native black bees. But the temper of all bees (Carniolans excepted) depend very much upon the way they are manipulated or handled, and to the odour from the persons handling them. Veils should on all occasions be worn by beginners until they know by experience when they can be dispensed with. I manipulated

my pure Punics many times during summer without any protection further than a carbolised feather.

AT THE HEATHER.

Bees are, as a rule, more spiteful at the Heather than when at home, and for that reason I always approach them at first veiled. Without this caution one sting might incur thousands, and make them intolerable to all who approached nearer than 100 yards, while even at that distance no one is safe from the furious crosses or the pure Italian and Syrian bees.

INOCULATION BY STINGS.

This to prevent after swelling is a popular fallacy, which I am prepared to prove to anyone who doubts it, and by many living witnesses. When at the Heather I came into a discussion with a professor in the clinical department, who at the time was unknown to me. I quoted its origin and made explanations, which he scouted, and fell back upon the vaccination with lymph being analogous. I explained to him the action of the acid of the sting of the bee upon the blood, and also its harmlessness upon the stomach, and asked him whether vaccine lymph would have similar results. The discussion was listened to by many people, amongst whom were several bee-keepers, who coincided with my experience.

FEEDING

being a common thing this year with many bee-keepers, beginners will, therefore, be none the worse by a little information upon the subject. From the 22nd September till the end of the month we had unabated wind and rain, so that my bees stand as they were, temporarily covered when brought from the Heather, but I permitted feeding through the day without risk of creating robbing. I caution beginners against attempting this until they become experienced. Better to feed at sunset or a little before, and never after dusk at first. It sometimes results in losing many bees, as they have a tendency to fly out.

PURE CANE SUGAR.

No other than this should be employed, the proportion of water to sugar being about equal in weight. The mixture often given of less than half of that quantity of water is liable to candy in the hive, and the bees may die amidst plenty. Bees prefer all syrup thin. The modern idea of thick feed is that it should be the consistency of natural food. It seems to be forgotten that honey is watery at first, and that the bees by certain processes render it thick.

BOTTOM FEEDING.

This is more natural for the bees and handier for the apiarist. The bees take food quicker up than down, while when feeding from below the crown of the hive is supposed to be covered, as it will be during winter, the bees store it in its proper place, and contiguous to the winter cluster, so that the food will never be out of the reach of the bees during a zero temperature, as it is sometimes with certain crown-fed hives. I have fed several hives with thick syrup to show beginners the soundness of this teaching. Thick syrup is altogether unsuitable for winter feeding. — A LANARKSHIRE BEE-KEEPER.

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Paradise Stocks (J. B.).—Paradise Stocks are simply more or less diminutive varieties of Apples. The French Paradise is the smallest in wood, leaves, and fruit, and the least useful. It is said to have been introduced from the East as *Pyrus malus pumila*. Then there are the English Paradise, which is stronger and better, yet precocious, the French and Dutch Doucin stocks, and others, all probably chosen from

seedlings by stock raisers in the same way that Mr. Rivers selected the very good Nonesuch and Broad-leaved Paradise stock from seedlings of the English Nonesuch Apple, because of their sturdy fruitful nature and surface-rooting proclivities.

Moisture for Orchids (T. C.).—Every case has its peculiarities, and, as the doctors say, strong measures have to be resorted to occasionally. The treatment advised proved beneficial in the case referred to. We have no doubt you find that the requisite amount of moisture for the Orchids under your charge is provided when there is a difference of between 4° and 5° in the day as registered by the dry and wet bulb thermometers and 1° or 2° during the night; but all the same, the writer of the note you criticise is not a less successful cultivator of Orchids than yourself, and the large number of plants in his charge are in the best possible condition.

Caterpillars on Pear Leaves (W. J. M., Clonmel).—These will produce a small moth of the Tortrix family, named *Spilonota roborana*, which feeds upon the Rose, also upon the Apple and Pear. The ravages of the early or spring brood are more frequently noticed, but there appears to be generally a second brood, which sometimes feed in the autumn as in the present instance. Probably the application you mention would be of service to some extent, but any wash used to kill must be applied with considerable force, since the caterpillars are well hidden in the leaves. Some have found very efficacious for caterpillars of this and kindred species a mixture composed of Gishurst compound and tobacco water, or a wash of soft soap alone applied freely.

Plants for Bed and Pond (A. B.).—It would be best to occupy the bed with the hardier kinds of bulbs in winter, such as Winter Aconite, Snowdrop, Scillas, Hyacinths, Narcissi, and Tulips, and in summer with the ordinary class of bedding plants, such as Zonal Pelargoniums edged with Lobelia, Golden Feather Pyrethrum and similar plants. The bulbs should be planted this autumn. For the pond you may have *Aponogeton distachyon*, *Nymphaea alba*, *N. odorata*, *Nuphar pumilum*, and *Pontederia cordata*; plant those in not less than 12 inches, not more than 2 feet of depth of water. For the margin or in shallow water, *Iris pseud-acorus*, *Caltha palustris*, *C. palustris minor plena*, *C. palustris monstrosa plena*, *Menyanthes trifoliata*, *Ranunculus Lingua*, *Primula rosea*, and *Butomus unbellatus*. They are best planted in spring, about the middle to the end of April.

Tomato Sauce (R. G.).—As the recipes from your friends are not such as you require, as containing "cayenne and other strong things," we cite two others from Mr. Iggulden's manual, which all Tomato growers and users should possess:—1 (French), Cut ten or a dozen Tomatoes into quarters, and put them into a saucepan, with four Onions sliced, a little Parsley, Thyme, one Clove, and a quarter of a pound of butter. Set the saucepan on the fire, stirring occasionally for three-quarters of an hour. Strain the sauce through a horsehair sieve, and it is then ready for use. 2 (Italian), Take twelve or fifteen Tomatoes, a bit of butter, a little salt, half a dozen allspice, a little Indian saffron, and a glass of stock. Slice five or six Onions, and put the whole into a saucepan. Set it on the fire and stir frequently, as the mixture is apt to stick. When the sauce is observed to be tolerably thick, strain it like a *purée*.

Hyacinths and Tulips in Pots (J. B.).—About six weeks are required for the pots to remain plunged in ashes after the bulbs are potted. In the absence of ashes sand may be employed, and if of a sharp gritty nature is quite as good. We invert a small pot over the bulb of the Hyacinth, and cover with about 6 inches of cocoa-nut fibre refuse. As both the Hyacinths and Tulips will have grown somewhat when they are removed from the plunging material, care must be taken not to expose them suddenly to strong light or powerful sun, but they must be gradually inured to it, so as to prevent the foliage being damaged. Placed in a light airy position in a greenhouse, they will flower in March and April. The Tulips we presume are of the usual early varieties. A suitable compost for potting the bulbs is turfy loam of medium texture broken up moderately fine, to which add a fifth of well decayed manure or a fourth of leaf soil and a sixth of sharp sand. A quart of soot may be added to every bushel of compost, and the whole thoroughly incorporated.

Spearmint and Peppermint (W. J. M.).—Spearmint, or Green-mint, is *Mentha viridis* a native of Britain, in marshy places. The plant has a strong, aromatic odour, with a warm and slightly bitter taste, which is less pungent, but more agreeable than that of peppermint. The properties of the plant depend on a volatile oil, obtained by distillation. Oil of Spearmint is pale yellow or greenish when fresh, but becomes darker with age, and ultimately of a mahogany colour; it is used for the same purposes as oil of Peppermint. Its specific gravity is 0.975, and its boiling point 320°. Peppermint (*M. piperita*) is also a native of Britain. The plant has a warm, pungent, and camphorous taste, leaving a remarkably cold sensation in the mouth. Its odour is very strong, balsamic, and penetrating, particularly when touched, and which it does not lose, even in drying. Peppermint is stimulant and aromatic, and is good against nausea and flatulence. Its properties are owing to the presence of a large quantity of volatile oil which it contains, and is obtained by distillation. Oil of Peppermint is greenish yellow, and has a strong aromatic odour, with a warm, camphorous, and very pungent taste. Its specific gravity is 0.920, and its boiling point 365°. It is often adulterated with alcohol, and even with oil of turpentine. Combined with alcohol it forms essence of Peppermint, and it is used medicinally as a carminative and stimulant, as well as in confectionery for flavouring bonbons. Peppermint water, obtained by distillation, is very much employed in tonic, cordial, and anti-spasmodic drinks.

Eelworms Infesting Tomato Plants (X. Y. Z.).—We do not think we should advise you to pull up the worst plants and plant others in their places without making an entire change of soil, but rather to pull up and burn the plants most attacked, and seek to impart vigour into those least affected by dressings of bonemeal, sulphate of potash, and sulphate of ammonia. What effect this has had upon them you fail to note, though you say nearly all the remainder of the plants in the house have the same complaint. You ask for a dressing that will destroy the nematodes after you have removed 6 inches of the surface soil. We regret to say we know of no dressing that would destroy the insects that pass from the plants in autumn into the surrounding soil, ready to make their way to the new crop of food plants the following spring. Should there be any upon which they feed within their reach, that would not render the soil unfit for the growth of the plants. Some species of *Tylenchus* have the property of reviving in moisture after being apparently dried up for many months, or for years. No cold that we experience will destroy them; they endure extremes of heat up to 125° without injury, and they live in water alone for a lengthened period. They are not harmed by vegetable poisons, but they succumb to solutions of acids and most of the metallic compounds, especially to copper. This, however, cannot be applied to the soil without endangering the growth of the plants, and proving injurious, if not fatal, to human life. Sulphate of iron may be used at the rate of 1 ounce per square yard, and be mixed with the soil a foot deep after you have removed the 6 inches. This is some check on the Nematodes, but the only safe and sure remedy is to remove every particle of soil as deep and wide as the roots have penetrated, and not use it again for plants which are liable to attacks of eelworms, or, better still, subject it to a temperature not less than boiling point (212°) over a wood fire. That is a never-failing remedy, and often improves the soil for the growth of plants liable to be infested by eelworms at times, because it destroys vegetable matter, and so gives a larger percentage of mineral substances, particularly of potash and soda. Stable or farmyard manure is also liable to introduce the eelworms from diseased to healthy plants. We advise the use of fresh soil, and save seed only, if at all, from plants in which the disease has not appeared.

Names of Fruits.—*Notice.*—Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. *In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing.* The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*Ugbrooke*).—1, Minchull Crab; 2, Autumn Pearmain; 3, a malformed specimen of Greenup's Pippin; 4, Alfriston; 5, Bramley's Seedling. (*N.*).—1, Pear quite rotten at the core, worthless; 2, Blenheim Pippin; 3, Bedfordshire Foundling; 4, Dumelow's Seedling. (*J. J. D.*).—1, Maréchal de Cour; 3, Flemish Beauty; 4, King of the Pippins; 5, Summer Whorle; 6, Winter Codlin. (*H. J. W.*).—1, Probably local, and of little merit; 2, Potts' Seedling, a serviceable variety. (*W. M. B.*).—1, Beurré d'Anjou; 2, Beurré Diel; 3, Nec Plus Meuris. Continue your course of obtaining the paper, and send the extra copy to a friend. (*Alex. Haggart*).—The large Apples very closely resemble Flower of Kent, too closely, we think, for the variety to be regarded as distinct. Flower of Kent is a very old and good kitchen Apple, and was mentioned by Parkinson in the time of Shakespeare. (*A. Burness*).—1, Dumelow's Seedling; 3, Kerry Pippin; 4, Scarlet Nonpareil; 5, Rosemary Russet; 6, Easter Beurré, cracked and spotted through the soil being poor and probably sandy. **Special Note.**—We have named all the fruit that has been received up to the time of going to press in conformity with the above conditions. We have both boxes and baskets of fruit which cannot be named because the names of the senders were not enclosed with the specimens. Letters and cards posted separately obviously do not enable us to determine to which they refer. It is absolutely essential that the names of senders of fruit be placed *in the parcels*. It is as disappointing to us as to our correspondents that so many fruits cannot be named for the reason stated.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*E. J. T.*).—*Sedum spectabile*, also known as *S. Fabaria*. (*Taylor*).—1, *Onychium japonicum*; 2, *Adiantum Capillus-Veneris*; 3, either *A. scutum* or *A. tenerum*, cannot tell from small specimen; 4, *Pteris hastata*; 5, *P. serrulata cristata*; 6, *Adiantum gracillimum*. (*W. E. J.*).—*Ajuga*, send when in flower. (*F. A. B.*).—*A. Brunsvigia*, but send fresh flowers or a description of the plant. Compare with *B. Josephinae*. (*C. W., Bucks*).—1, *Cotoneaster microphylla*; 2, *A. Ceanothus*, possibly *C. rigidus*; 3, *Crataegus pyracantha* or *C. Lelandi*, specimen insufficient; 4, *Escallonia macrantha*; 5, Perhaps *Biota aurea*; 6, Possibly *Thuja dolabrata variegata*. No one can name shrubs with certainty from such diminutive scraps.

TRADE CATALOGUES RECEIVED.

Thomas Knight, Moss Side Nurseries, Ashton-under-Lyne.—*Dutch and French Flower Roots*.
J. R. Pearson & Sons, Chilwell Nurseries, Notts.—*Hardy Fruits for the Midlands, Roses, Evergreens, &c.*

DAIRY FARMING.

AFTER building up a national reputation for the production of butter of uniform quality, with every advantage of State aid and scientific supervision, the dairy farmers of both Sweden and Denmark found that the margin of profit was so small as to yield a poor return for efforts so thorough and purpose so earnest as theirs. Gradually, step by step, they have become as skilful in selling as in making their butter. Finding so large a share of their legitimate profits absorbed by middlemen, they have by means of co-operation effected change after change, till at length the establishment of shops in this country has brought them face to face with their best customers. In doing this they have shown what capacity, determination,

perseverance—aye, and business acumen—will do. So impressed is the Board of Agriculture of this country by all this, that it has recently published full and lengthy particulars of it, obviously for the benefit of British dairy farmers, making the matter sufficiently clear for the comprehension of ordinary minds.

Surely this is a step in the right direction, to be regarded as holding out a helping hand to farmers in difficulties. It is a word to the wise, which comes to us at a time when the difficulties of dairy farmers have exceptional prominence accorded them, from the action of Lancashire men in their cry for help to landowners and the Legislature. "Help yourselves!" is the answer to their appeal, "and let the spirit of co-operation shown by the Preston manifesto lead you to combine in similar efforts to overcome difficulties which the farmers of Sweden and Denmark have shown and are showing you are not insuperable." On behalf of our own farmers we ask, Is their appeal to the Legislature altogether uncalled for? May we not hope that State aid will at least be accorded them upon somewhat similar lines to those in force in Denmark, where Government rules for the management of dairy and cowhouse are enforced by competent inspectors? Any annoyance resulting from such interference must be counterbalanced by the advantage of the advice and guidance of skilful scientific practitioners. Many times we have known worthy farmers at a loss when cows have fallen off prematurely in the milk yield, or in the treatment of the ailments of one kind or other which occur in all herds. What a boon to them would be the right, as it would be their duty by law to have Government assistance in their difficulties!

Though the provision of a proper and seasonable dietary would be enforced, the establishment of suitable cowhouses and other means of shelter, according to the requirements of each homestead, would also have similar authoritative attention. With this would come, too, means of prevention of the enfeebled condition which so frequently leads to disease. Such means are wanting on many farms now, and where they are available are but too often not turned to account from ignorance of their true value and use. Another much wanted improvement would be found in the better class of cows, not mere show animals, but in which a greater milk yield would be developed. That this point, so advantageous to the farmer, would be constantly impressed upon him is certain, and it is reasonable to suppose it would then have the attention it deserves. Self interest should prove a sufficient incentive in this, yet it evidently is not so, and it remains for a spirit of emulation, which would probably spring from closer contact with others, to incite more attention to careful breeding.

Given such a reform as we have thus briefly indicated, it only brings us to the better production of milk. There is still before us the vital question, What is to be done with it? We repeat, that if it could be arranged for farmers near large towns to sell milk, and those outside a given radius to turn their milk to account for making cheese and butter, it would be to the mutual advantage of farmers generally. Now we hear frequent complaints of the low price of milk. We shall continue to do so while it is sent to London from farms upwards of a hundred miles off. In the *Melton Mowbray Times* of September 23rd there was an advertisement by a large London dairy company for "first-class dairies of milk, cheques weekly, and all churns found." While such advertisements have attention, can we wonder at the low price of milk? The remedy is to be found in the systematic establishment of co-operative dairy factories by milk producers, who would thus obtain a ready sale for their milk at a fair price, and also participate in the profits of the concern. Who will be the first to move? In Munster, after much discussion and hesitation, a public spirited farmer led the way. He had sufficient influence to induce others to combine

with him to start the first factory, and the success which they had with their bold venture was a veritable beacon light to other farmers, who soon followed the excellent example set them, and who have found their cows become 30 per cent. more valuable under a scheme which is proving such a blessing and relief to the south of Ireland.

WORK ON THE HOME FARM.

First let us correct an error in our work note of September 22nd, in which by an inadvertence it was stated that land in course of preparation for fruit farming should be ready for planting early in September. We of course intended to say November, and would urge all who intend planting fruit trees or bushes this season to be ready with land and trees by the first week of that month. You may plant from then till spring in favourable weather, but the work can never be done to such advantage as early in November. The roots then become sufficiently established in the soil to render robust vigorous growth a certainty next year. If planting is put off indefinitely till late in the season the trees will live if properly cared for, but they will put forth no useful growth, so that a year is practically wasted. In the formation of new fruit plantations attend to the due provision of shelter by planting mixed belts of Lombardy Poplar and Austrian Pine, which then gain size with the fruit trees, affording really useful shelter by the time the latter are well in bearing.

Keep calves shut in except on warm dry days; those left out on pasture in all weather have now much dry husky cough among them, and there will be losses from what is practically a preventible disease. Clear out all surplus or weakly live stock at any price; it is much better to make a considerable sacrifice now than run the risk of being short of food next Ladyday. Consider ways and means carefully, allowing a considerable margin in the winter store of food for a hard winter and late spring. It is a good rule to make a point of having a stack of hay in reserve at turn-out time in spring. The thing is quite easy of management if only the head of stock is kept within due bounds. Clear off fat beasts from pasture to the butcher as quickly as possible, avoiding any stall-fed beasts as a rule, for they cannot answer at the present low prices. Besides cows and heifers the only store cattle profitable to winter now are the calves of last spring, and steers calved in the spring of 1891, which if brought into the yards now in good condition, kept so till next spring, and grazed well till the autumn, should answer well and prove fairly profitable. But there must be no cake bills; the farm must be self-supporting.

OUR LETTER BOX.

Parsnips for Dairy Cows (W. R. R.).—Parsnips in moderate quantities may be used advantageously for dairy cows. They are not generally favoured by farmers as a root crop because they require a deep rich soil to give thick clean roots. Sown in shallow soil they put forth so many forked roots that the main root is comparatively worthless; the crop is both difficult to lift and to clean. In deep rich loam we have found Parsnips answer admirably, growing freely and well, and affording a very valuable supply of food for cows in winter. Give heed to our hint about moderation in the use of this root, so as not to run any risk of imparting unpleasant flavour to the butter. Sow early in March, using about 3 lbs. of new seed per acre. Lift the roots in October; they bear frost well, but it is best to have them off the land before it becomes saturated with the heavy rains of autumn.

REMARKS.

- 25th.—Generally sunny in morning, fair afternoon, clear evening.
 26th.—Cloudy early, generally sunny after 10.30 A.M.
 27th.—Fair, with one or two gleams of sun; rain at night.
 28th.—Fine and generally sunny.
 29th.—Brilliant till 11.30 A.M., slight shower at noon, cloudy afternoon, with high wind and occasional spots of rain; steady heavy rain from 6 P.M. to 6.30 A.M. on 30th.
 30th.—Steady heavy rain till 6.30 A.M., a little sun about 11.30 A.M., heavy shower of rain and hail at 0.15 P.M., sunny afternoon, rain at night; a loud peal of thunder about 11.30 P.M.
 1st.—Heavy rain from 8.30 A.M. to 0.30 P.M., sunshine from 1 P.M., fair evening.
 A week of average temperature and considerable rainfall, but the last week of October is frequently wet.—G. J. SYMONS.

"TIME'S tyrannic sway" deals hardly with workers in the great field of horticulture, and with the material that their hands had fashioned, for the gardener is called away from his sphere of love and labour, while the flower gives place to an improved rival; but, safely enshrined in the records of horticultural progress, literary contributions live on to afford instruction and delight to succeeding generations. Few—save those who have turned over with a reverent and sympathetic hand the pages of the past, making imaginary headway against the fleeting tide of time, and living for a few hours with the gardeners and writers of fifty years ago—can realise how much we owe to our fathers' teaching. What if, in some cases, the style appears quaint and stilted? The germ of good was there, and, far from smiling at the stately cadences, we should see nothing but what is admirable in the literary work of the gardeners whose labours to clothe their thoughts in clear and intelligible language was not aided by the early education which is now enjoyed. As for the leaders of the circle of writers who flourished fifty years ago, their work speaks of sound knowledge, ripe judgment, and a literary skill not surpassed at the present time. When G. W. Johnson, Donald Beaton, Robert Fish, and R. Errington were writing in the *Cottage Gardener* horticultural literature was in its brightest phase, and it is not too much to say that the marked ability which characterises the writings of the present school of gardeners is the fruit of the example set by those brilliant men. They were by no means alone. Good work was done by many others, and a general high level was reached, the maintenance of which has given horticultural literature the highest place amongst that of special industries.

Apart, too, from the regular contributors to the gardening periodicals there have been contributions of great value from others to whom writing has been a pastime pursued in the leisure moments of busy business lives—stray leaves scattered in this quarter and that, but all helping to enrich the general store of knowledge. Of such are the essays, articles, and lectures written and delivered over a period of fifty years by Mr. William Paul, and the most important of which he has, by a happy inspiration, gathered together and published in a handsome and beautifully printed volume,* thus bringing into compact compass the scattered fragments of one of the most cultured horticulturists of our day. Wm. Paul wrote when Beaton did, and his firm bright intellect still delights us. The 562 pages of the volume before us are a record of practical knowledge, taste, and literary skill of no common kind, and the highest praise that can be bestowed on the book is to say that many of the chapters read as freshly as they did thirty, forty, or fifty years ago. The volume, which is dedicated to Dr. Hogg "as a mark of respect and esteem arising from a lifelong friendship" is divided into three parts, the first being devoted to Roses, the second to trees and plants, and the third to fruit culture and miscellanea. Mr. William Paul's eminence as a rosarian gives a special interest to the opening part, but as a horticulturist of considerable all-round knowledge, a calm thinker, and a man of taste and culture there is no chapter in the book that has not weight, value, and significance. It would appear that forty-nine years have elapsed since Mr. Paul's first communication on Roses

was published, this consisting of an article contributed to the "Gardeners' Chronicle," then edited by Dr. Lindley, on Roses in pots, and it was followed by others, these proving the then young writer to possess far more than a smattering of the practical knowledge which he displayed in dealing with the same subject later in life, and which, it may be noted, he has made peculiarly his own. One of the most interesting points of the chapter is to observe how widely lists of varieties varied from their present character. The change gives an idea of the great progress which has been made in the time that has elapsed since the article was written. For instance, the list of Hybrid Perpetuals recommended by Mr. Paul comprised nineteen, not one of which is in general cultivation now. Their names are as follows:—

"Auberon, Clementine Duval, Comte de Paris, Coquette de Montmorency, Dr. Marx, Duc d'Aumale, Duchess of Sutherland, Edward Jesse, Fulgorie, General Merlin, Lady Alice Peel, Louis Bonaparte, Madame Laffay, Mrs. Elliot, Prince of Wales, Prudence Roeser, Princesse Hélène, Queen Victoria, Rivers."

Almost as much might be said of the Teas:—

"Adam, Archiduchesse Thèrese, Barbot, Belle Archinto, Bougère, Bride of Abydos, Caroline, Comte de Paris, Devoniensis, Don Carlos, Elise Sauvage, Eugène Desgâches, Fragoletta, Goubault, Hamon, Julie Mansais, Madame Roussel, Josephine Malton, Moiret, Niphetos, Nina, Pactolus, Prince d'Esterhazy, Safrano, Taglioni."

Out of these, four—namely, Adam, Devoniensis, Niphetos, and Safrano, are still widely grown, and the last two are considered nearly indispensable. There could be no stronger tribute to their intrinsic excellence than the fact that the labours of fifty years in the improvement of this beautiful class have left their positions still impregnable. The train of thought suggested by this consideration of new and old varieties is carried further by the chapter on a trip to Paris in search of autumnal Roses in 1844.

"The History and Cultivation of the Rose" (page 21-42) forms one of the most complete, interesting, and valuable chapters in the book. It was delivered as a lecture to the Stamford Hill, Clapton, and Stoke Newington Gardeners' Association in 1845. "Who," says Mr. Paul, "were the first people to bring this flower from its natural habitat to be a dweller in cultivated grounds must ever be a matter of conjecture." He thinks, however, that it attracted notice at a very early period. That its great beauty has always given it a prominent position, even from the earliest times, is proved by the many references to it by the early writers, such as Theocritus, Homer, Sappho, Anacreon, Pliny, and Suetonius. Moreover, it has always stood as the symbol of floral beauty, appealing to poets and prose writers of all nations. Among those who have sung of it in the English tongue the author mentions Chaucer, Spenser, Shakespeare, Beaumont, Milton, Byron, Moore, Cowper, and Mrs. Hemans—a truly noble throng.

The first foreign Rose introduced into this country was, he tells us, the Damask, *Rosa damascena*, which came in 1573. The year 1596 is given as the period of introduction of the Provence (*R. centifolia*), the Moss (*R. centifolia muscosa*), the French (*R. gallica*), the Musk (*R. moschata*), and the Austrian (*R. lutea*), while *R. alba* followed in the succeeding year. "Here," said Mr. Paul forty-seven years ago, with an excursion into the realms of prophecy that time has abundantly justified, "were the progenitors of several of the most popular Roses of the present day brought to our shores at about the same period. Beautiful as they no doubt were then considered, highly as they would be prized by the scientific in those matters, who could have dived so far into the ocean of futurity as to foresee that from these species would spring forth the admirable varieties we at present possess? But we know it has been so, and in contemplating still further improvements by the process of hybridisation, what extensive prospects open upon our view? The field for experiment is boundless, and

*Contributions to Horticultural Literature, 1818-1892, by William Paul. Published by W. Paul & Son, Waltham Cross.

I believe yet brighter gems lie hidden undeveloped in the forms of these species and their varieties."

The double yellow Rose (*R. sulphurea*) was introduced about 1629, also the Evergreen Rose (*R. sempervirens*), while the Boursault Rose came in 1683. More than 100 years elapsed before the introduction of the Chinese Rose (*R. indica*) which served, as the following extract shows, as a portion of the foundation of the great H.P. class.

"From the Chinese crossed with the Gallica or French Roses have sprung the Hybrid Chinese, one of the finest groups of the whole. From these, again crossed with the Bourbons and Damask Perpetuals, have arisen another admirable group, the Hybrid Perpetual. These are, in reality, Hybrid Chinese continuing to flower during autumn, and are very hardy Roses."

Pursuing the historical portion of the subject, which cannot fail to interest many, we find that the Macartney Rose (*R. bracteata*) was introduced in 1795, *Rosa multiflora* in 1804, *Rosa Banksiae* in 1807, and the Tea-scented, which, like the Banksian and others, came from China, in 1810. *R. Lawrenciana* was also introduced in 1810, and the Noisette was sent to Paris from America, "where it was supposed to have been raised from a cross between *R. indica* and *R. moschata*" in 1817. Doubtless it reached England very little later. The same might be hazarded of the Bourbon Rose, sent to France from the Mauritius in 1822. *R. microphylla* was introduced in 1828, and *R. rubifolia* in 1830. We need not quote the cultural remarks of these on pruning, but in reading them with the recollection that they were written nearly half a century ago we recognise that they outlived the recognised practice of to-day.

"A Plea for Summer Roses," published in 1846; "Morning Rambles in the Rose Gardens of Hertfordshire," published in 1849; and "Tea-scented Roses as Conservatory Climbers," also published in 1849, contain much of interest and instruction, but there is still more in the series commenced in 1863. This consisted of a general opening article, two chapters on summer Roses, five on autumnal varieties, one on Tea-scented, and a final one on brief rules of culture. Rose shows, garden Roses, bedding Roses, thoughts on Roses, fast life among the Roses, Roses and Rose showing, Roses in pots, Roses at the Royal Botanic Society, and Roses and Rose shows, all form pleasant and profitable chapters. One of the most valuable in the book, however, is that on "the Grouping of the Garden Varieties of Roses," read at a conference of the Royal Horticultural Society in 1889, thus bringing the book up to a comparatively recent date; while the last, on town Roses, which appeared in our columns in July of the present year, forms a practical and useful conclusion of Part I.

In no way inferior in interest or value are the numerous communications gathered together in Part II. on trees and plants, which are excellent in themselves and a striking proof of the versatility of the author. He deals with such diversified subjects as the varieties of the common Yew, the varieties of English Holly, landscape gardening, ornamental planting, hardy pictorial trees, trees and shrubs in large towns, an hour with the Hollyhock, Hyacinths, Zonal Pelargoniums in winter, spring flowers, and Camellias. The chapter on the latter is very complete and full of information on culture and varieties. Half a dozen questions propounded by Mr. Paul and then answered are worth quoting with their replies.

"1, Why are Camellias scrubby?—Answer, Because in cutting off the flowers they are usually cut with long stalks, and thus the eyes or wood-buds best stored with food are cut away and the new growth thrown on to eyes with a limited supply of food at their command. Or, as another and wholly distinct cause, insufficient heat or moisture is supplied during the period of growth.

"2, Why are Camellias mis-shapen?—Answer, Because the trees are not pruned sufficiently, or are pruned at the wrong season.

"3, Why are Camellias so often seen bearing feeble branches?—Answer, Because they are not sufficiently nourished. This may be that they are grown in an unsuitable soil; it may be that too little moisture and heat are given during the period of growth; or it

may be that the soil becomes soddened from insufficient drainage or too much water when the plants are not growing or flowering.

"4, Why are the leaves of Camellias yellow?—Answer, Because grown in an unsuitable soil, or kept too dry when flowering and growing, or too wet when in a state of comparative rest.

"5, Why do the flowers of Camellias expand indifferently?—Answer, It is with Camellias as with Roses, some kinds—*Valtavedo*, for example—are so full, or the petals are so tightly folded, that the flowers will not expand fully in our climate without the aid of heat. However healthy and satisfactory the plants may otherwise be, such kinds require more heat and moisture than is good for others so soon as the buds show colour. But the same phenomenon is sometimes met with even in kinds not over-double. The cause, then, is unsuitability of soil, or too much or too little water.

"6, Why do the flowers drop off before expansion?—Answer, This is natural to some kinds, of which the *Waratah* is an example, and such kinds should be avoided. In other cases the causes are similar to those which bring about indifferent expansion—namely, bad soil and injudicious management of watering."

An important contribution to the third portion of the work is the article on fruit culture for profit in the open air in England, which was read before the Society of Arts in 1889. Mr. Paul sets forth the pros and cons fairly and moderately, supplementing them with much practical advice and information. He points out the advantages and disadvantages of our climate for profitable fruit culture, and indicates the salient features of successful procedure, notably the importance of a judicious selection of varieties.

"In this part of the business," says the author, "there is, perhaps, no guide so safe as that of actual experience. Sorts that are known to grow well and bear well in any particular district may, provided the produce sells well, be safely planted there. But this experience is always limited. Valuable guides in the selection of sorts are also to be found in the period of flowering and the frost-resisting powers of the blossoms.

"As regards the period of flowering, some sorts flower early, others late. A difference of three or four days often makes the difference of a crop or no crop, as in those three or four days a frost happens that destroys the embryo of the early or expanded blossoms, which leaves the unfolded buds unscathed, and this frost may not occur again in the same season. Then as to the frost-resisting power of the blossoms. This is not the same in all cases; some varieties appear naturally less susceptible of frost than others. Again, in some I have observed that the embryo is better protected by the size, form, and substance of the petals which surround it. In some cases the petals, when unfolding, fall into a horizontal position, leaving the embryo fully exposed; in others they remain incurved, offering material protection. Then the substance of the petals differs considerably, practically almost to the extent of the difference in our own clothing between a summer and a winter coat.

"It has often been a matter of surprise to me that these important facts have not commanded more attention from our horticulturists. Here statistics would be of immense value to the cultivator, and those who have the leisure and inclination to provide them would be rendering a national service in doing so."

Here correct observation is supplemented by a suggestion, the adoption of which would lead to the dissemination of much valuable information. The difference in substance observable in the blossom of different varieties of Apples forms the subject of another useful contribution, which originally appeared in our columns in 1890. This, and a table accompanying it, shows the date of flowering, the name, size, and shape of the flowers, the shape of the petals, and the substance of the latter of ninety-five varieties of Apples, and should be studied by every fruit grower.

Space only permits of a brief reference to other chapters, such as that on "The Literature of Ancient and Modern Gardening," read before the Royal Society of Literature in 1887, and we must conclude the imperfect record of more than one pleasant hour with Mr. Paul's work by the expression of a hope that the writer, who has added strength and dignity to horticultural literature for half a century, may have many years in which to use his pen for the pleasure and enlightenment of the generation growing up around him.

SEASONABLE NOTES.

AGAPANTHUS UMBELLATUS.

AGAPANTHUS UMBELLATUS, or the Blue African Lily as it is more often called, is such a well-known and popular plant that one hardly needs to make any remark whatever about it. Too much, however, can hardly be said in its favour, and no garden can be considered complete without it. The plants can be grown in large pots or tubs outside during the summer months, and are exceedingly useful for embellishing terraces, balconies, and steps. They are not quite hardy, and must be removed in the autumn, placing them where they will be protected from the frost, and during the winter they should be kept nearly dry.

As soon as the frosts are over they may be again placed in their summer quarters. During the summer, and especially in dry weather, the plants can hardly be overwatered, and liquid manure, if applied at intervals, would prove very beneficial to them, especially when they are throwing up their flower spikes. The heads of clear blue flowers are produced in great profusion during the summer and autumn months, the stems rising to a height of from 2 to 3 feet. One can imagine the beauty of such when associated with other well-known autumn flowers, although they require no "setting off" to exhibit their remarkable beauty. We have some large plants in tubs here carrying twelve to fifteen spikes on a plant, and averaging from seventy to ninety flowers on a spike.

CLEMATISES.

The Clematis is, perhaps, the most popular and valuable of all our hardy climbers. The profusion of their blooming, richness of colouring, and comparatively easy cultivation have raised them to the front ranks for covering walls, bowers, trellises, arches, and pillars, to all of which places they are well adapted. Few can have any idea of their beauty till they have seen them well grown. They continue in bloom from May till October, producing abundance of flowers during that period; and it is almost impossible to over-estimate the gorgeous effect these plants are capable of producing and maintaining during a very considerable period. I do not know of anything to surpass Clematis Jackmanni when planted in clumps or masses at intervals on the herbaceous borders.

COLCHICUMS.

Colchicums are without doubt some of the most beautiful of all the hardy autumnal flowering bulbous plants. They are similar to the Crocus in form and habit, but the flowers are much larger and are produced in the autumn. When planted in clumps, large masses, or edgings to beds and borders they produce a very fine effect.

ANEMONE JAPONICA.

Anemone japonica differs essentially from other species of this family of plants on account of its autumn-flowering habit. It is undoubtedly one of the best and most useful of our autumn blooming plants. The plants grow to a height of from 2 to 3 feet, and their flowers, which are produced in great profusion, are as much as 2 or 3 inches across. They will thrive in almost any situation, but if planted in good soil and given a favourable position much finer specimens can be produced. The flowers, which are borne on long footstalks, are most useful for cutting purposes, lasting a long time in water.

KNIPHOFIAS.

Kniphofias, or Tritomas as they are more commonly called, are very striking and ornamental autumn-flowering plants. They are, in fact, the most gorgeous of our outdoor plants, and for the wild garden, shrubbery, borders, or dotted about in sheltered places on the lawn, or planted at intervals along the carriage drive, few things are more effective during the autumn months. Their stately spikes of flame-coloured flowers rise to a height of from 3 to 4 feet,

and are most showy long after Dahlias and other autumn flowers are cut down by the frost. They are equally suitable for planting in lines where there is a background of green foliage, the latter being a most pleasing contrast to the orange-red of the Kniphofias. I have, however, never seen it to better advantage than when it is associated with Anemone japonica. The effect, when so employed, at this season of the year is really beautiful.—GEO. PARRANT, Ashby St. Ledgers Lodge, near Rugby.

RHODODENDRON MULTICOLOR NEPTUNE.

THIS plant was exhibited at the meeting of the Royal Horticultural Society on October 4th by Messrs. J. Veitch & Sons, Royal Exotic Nursery, Chelsea, and a first-class certificate was awarded to it. The specimen shown was like a miniature standard, about 1 foot high, and bore seven clusters of rich scarlet flowers, as represented in the engraving (fig. 44). The flowers are about 1½ inch in diameter, and are most effective. This Rhododendron is a greenhouse variety, and

FIG. 44.—RHODODENDRON MULTICOLOR NEPTUNE.

one of Mr. Heal's hybrids, but, like the type, will thrive best in a warmer temperature. When well known it will doubtless become a general favourite.

MICHAELMAS DAISIES.

MANY of the perennial Asters or Michaelmas Daisies have long been inmates of British gardens, but for many years their beauty and usefulness remained unrecognised and unappreciated. In this respect, however, they have only shared the fate of many other fine hardy flowers now being rescued from obscurity and neglect, and attaining to a height of popularity they never previously obtained. It is gratifying to see how much Michaelmas Daisies are admired and the great improvement that has been effected by their extended cultivation in gardens, and by the introduction or raising of new varieties.

That this improvement in the way of introducing or raising new sorts has been productive of good results will be readily admitted by those who have grown Asters for many years. Here and there one might have seen a few good plants, but in most instances the Michaelmas Daisies were only represented by varieties of somewhat ineffective colours, and in some cases even of ungainly habit. Now all this is being changed, and these useless varieties are being weeded out to give place to others of finer colour and more

graceful habit. And who can say too much in praise of many of these plants? They come to adorn our gardens with the most harmonious blendings of colour, when but for them the Sunflower and the Tritomas would make the garden brilliant but not beautiful. Many of them come into flower when there is but little else to brighten the garden late in October and November, and when but for them there would only be seen the ruins of the summer blossoms. Look, too, at the value of the flowers for cutting, many of them forming most graceful sprays of the highest degree of beauty. Then the hardiness of most of the varieties is unquestioned. The cultural care required is of the slightest, and apart from their beauty when in flower many of them are from an early period of growth of exquisitely graceful habit. With so many claims to our consideration it is evident that a great future is before the perennial Asters.

It is unfortunate, however, that so much confusion has existed, still exists, and is still likely to exist, regarding the nomenclature of the species and varieties. This is, I believe, unavoidable from the difficulty of distinguishing properly between the various species. Some years ago I carefully studied Dr. Asa Gray's monograph with a view to identifying some of the Asters in my garden. The task was an impossible one in many cases, so similar were many of the descriptions, and I understand this was the feeling of Dr. Gray himself. I can therefore fully appreciate the difficulty of the task before the Committee of the Royal Horticultural Society, which has in hand the revision of the nomenclature of the genus, and I can only hope that their nomenclature may be adopted by the trade, that nurserymen in general may have the names of their plants verified, so that the purchaser may know that the name he has with his plant is one given by a good authority. As it is, some of us have been well nigh in despair, so difficult has it been to get plants true to name, or to give the true names to those received or picked up without a designation. It does seem a little strange, however, to find classed along with the varieties of *novi-belgii*—mostly of tall stature—such plants as *A. novi-belgii* Pleiad and *A. n.-b.* Pygmalion, each only growing about 1½ foot in height. I have not the slightest wish to doubt the correctness of the classification, I accept it unreservedly; but it shows us how one's preconceived views may be rudely shattered by a conference of experts.

As already indicated little difficulty will be experienced in the cultivation of most of the Michaelmas Daisies. Almost any soil or any situation will suit the vast majority of the species or varieties, the exceptions being one or two species, such as *A. diplostaphioides*. Nearly all will do as well on a light soil as on a strong, heavy one, provided that a sufficient supply of water can be given in dry weather. Should this not be available the plants frequently lose some of their lower leaves, and their beauty is consequently much impaired. Like the Chrysanthemum, their attractiveness is greatly enhanced when the foliage is in perfect condition, and on light soils every attention should be given in order that they do not suffer from drought.

It is somewhat difficult in the present condition of the nomenclature to give a selection of the best kinds. Indeed, when it is at all practicable, it would be well for the purchaser to see the plants in growth before making a choice. This is, however, seldom convenient, and the notes which follow are intended to indicate some of the best and most distinct of the forms. It must of course be understood that the heights given are only approximate ones, as the plants vary much according to the soil and supply of moisture. There are plants among the Asters suitable for almost any position, and even the rockery may be decorated with some of the less vigorous growing species. Well known among these is the dwarf but beautiful, little *A. alpinus*, flowering early in July, and bearing good-sized bright purple flowers on stems from 6 to 9 inches in height. The white variety is very pretty also, and the newer *A. alpinus speciosus* is exceedingly fine indeed with its large violet-blue flowers in July. Such species as *A. Stracheyi*, with pale blue flowers on stems 4 to 6 inches high, are also useful for this purpose; while for rougher rockwork some of the dwarfer forms of the other species might almost be included.

It is as border plants, however, that the Michaelmas Daisies are most valuable, and foremost among them is the useful and beautiful well known *A. longifolius formosus*. This is of graceful habit, and when in full bloom is literally covered with bright crimson flowers. There seems to be considerable variation among the plants supplied under this name, and an Aster I saw under the name of *A. Madame Soymier* appears to differ only in a slight degree from some of these. All are very beautiful, however, and growing only to about 2 feet in height they will be found very useful. Exquisitely graceful, too, is *A. ericoides*, only just beginning to open here and in Edinburgh. This grows about 2½ or 3 feet in height, and has beautiful sprays of small white flowers. Another very beautiful Aster which I have had for over fifteen years is

A. diffusus horizontalis, forming a beautiful bush composed of branching stems of deep green, almost purple, foliage, literally swarming with small white flowers with red centres. This generally flowers with me in November, and withstands the most severe frosts in this locality.

Among the most beautiful species of tall habit is *A. novæ-angliæ* growing 5 feet or more in height, flowering with me well into October and having fine rose-coloured flowers. The variety *A. n.-a. ruber* is, however, of finer colour than the type. The varieties of *A. novi-belgii* are now very numerous, and it is difficult to select the best. I find *formosissimus*, growing about 4 feet high with rosy lilac flowers in October, to be one of the best of the tall varieties. *A. n.-b. Robert Parker* is also a good variety. Very beautiful and very distinct is *A. pyrenæus*, which, unlike most of the others which are generally natives of America or the Himalayas, is a native of the Pyrenees. This grows about 2 feet high and has fine violet flowers with slightly reflexed petals. Of specially fine colour, although with less perfectly formed flowers than some, is *A. spectabilis*, also growing about 2 feet high with flowers of exquisite blue-purple. Seldom seen is *A. Thomsoni*, growing here about 3 feet high with fine flowers of what one might call a crimson blush. Of a somewhat similar colour, but whiter, and also of dwarfer habit, is *A. salsuginosus* growing about 18 inches in height.

To speak of so many species and varieties in detail would occupy too much space, and most of the others can only be mentioned. I should not like, however, to omit drawing special attention to an allied plant which I have as *Galatella linifolia*, but which is, I understand, also known as *Aster linarioides*. This grows about 3 feet high and has narrow, pretty foliage and is completely covered with flowers of a fine purple. It comes into flower in the end of July, and is not yet out of bloom although past its best. Very desirable plants also are *A. novæ-angliæ pulchellus*, deep violet; *A. amellus*, deep blue, 2½ feet; *A. speciosus superbus*; *A. lævis*, deep blue, 5 feet; and *A. puniceus*, blue, about 3 feet high and flowering in August. Those who admire the white-flowering sorts will find *novi-belgii Harpur Crewe* and *n.-b. John Wood* to be well worth growing.

With a good selection of Asters and a number of the best of our autumn flowering plants a garden may be rendered interesting until near the close of the year, and it is to be hoped that many will embark in the cultivation of these fine flowers which seem to mock at the inclemency of wintry days and to brighten up the borders which without them would be dull and bare.—S. ARNOTT.

DISCUSSION ON APPLES.

ROYAL JUBILEE.

WHILE the discussion is going on in the *Journal* on the merits and demerits of certain Apples I thought perhaps a note on Graham's Royal Jubilee might be interesting to some of your readers. The tree of this variety which I possess was purchased two years ago from Messrs. G. Bunyard & Co. It is a small pyramid, and did not bear any fruit last year, but this season up till the first week in August it bore fifteen fine Apples, during which month, however, three dropped. I picked the remaining twelve last week and weighed them. Together they turned the scales at 7 lbs., the largest weighing 12½ ozs. Although carrying such a heavy crop the tree has made an average growth of 8 inches. I may say that the Apples have been admired by all who have seen them. I would advise fruit growers to give this variety a trial, and I do not think they will be disappointed. This is also the opinion of other practical men in this neighbourhood.—W. PASCOE, *Sydney Lodge, Hamble, near Southampton.*

HAMBLEDON DEUX ANS.

UNFORTUNATELY this has been the favourite Apple amongst the cottagers in this neighbourhood for many years to the exclusion of nearly all other sorts. The result is that nearly every garden in which an Apple tree is growing possesses one of this sort, which originated eight miles from here, and is sometimes called the Green Blenheim. Although this is a free bearer and a good keeping sort in most cases the quality is bad, even for cooking. There are exceptions, but that is owing mainly to the kind of soil in which the particular trees are growing. Hereabouts it is said there are two sorts. A person gathered thirty bushels of this sort last week, which realised an offer of 2s. per bushel, whereas if Ecklinville or Warner's King had been in question these would have brought considerably more.—E. M., *Swanmore, Hants.*

MÈRE DE MÉNAGE.

ALTHOUGH this Apple is generally looked upon as a shy bearer it is not so in all cases. I can testify to its regularity in producing

good crops for the last ten years, and this year the trees here are laden with extremely highly coloured fruit. The method of pruning and training practised may have something to do with the free cropping qualities of our trees. The branches are kept very thin, all side growths being freely pinched off during the summer. The points of the branches are allowed to extend almost as long as they choose; plenty are now 4 feet long without any side shoots. These branches are simply wreathed with fruit, which in our strong calcareous soil never fail to colour splendidly. Although our trees are regarded as bushes they are now 15 feet high, and were it not for the difficulty in gathering the fruit I should allow them to grow still higher.—E. M.

BRAMLEY'S SEEDLING.

My experience with this variety is somewhat limited, but from its appearance and manner of growth and cropping propensities I am positive it is an Apple that should be grown for late use. It keeps well into April, and some say longer; anyhow it has all the appearance of so doing. The tree is an excellent grower, not one of those long lanky shoot-makers, but very sturdy both in foliage and wood; the leaves are intensely dark green. Standard trees planted here in November, 1890, are bearing heavy crops of large, highly coloured fruit, which are, perhaps, not very handsome to look at, being somewhat flat with a deep eye. This variety, however, has all the characteristics of what is claimed for it, being a free grower, heavy cropper, and late keeper. It is said to grow freely in any soil.—E. M.

TOWER OF GLAMIS.

In a young state the trees of this variety are certainly far from being as precocious as Prince Albert, Bramley's Seedling, Jolly Beggar, Duchess of Oldenburg, and a few other now very popular Apples; but when they attain a fairly large size, or say any age, from six years and upwards, no possible fault can be found with them. It seems somewhat impatient of hard pruning or stopping; but if healthy trees are "given their head," there is no mistake about their cropping qualities. Since I have allowed a previously closely pruned tree to form a number of fresh branches the improvement has been most marked. Nearly every season these young branches are weighted down with very fine fruit; and this season the crop is better than I have ever previously seen of the variety, and that, too, in spite of a heavy weight of fruit being taken from the tree last year. Tower of Glamis is a fine Apple, the fruit being extra large, somewhat conical in form with rather high "shoulders," that is to say, prominent ridges, while the colour at first is pale green, changing to a clear yellow. It is in season from November to the end of January, and is an excellent cooking Apple. I have had no experience with this old variety on a dwarfing stock, but can strongly recommend it on the Crab stock and low stems for planting where plenty of room can be given it.—W. IGGULDEN.

BEAUTY OF HANTS.

This is supposed to be a seedling from Blenheim Orange, and by some said to possess the quality of its parent, but in point of flavour I have not found it equal to the old favourite. The tree is a wonderful cropper; our one standard has more fruit on it than any other in the orchard for its size, and we have some very full crops. The fruit is smaller than the true Blenheim, but exactly the same shape. Where Blenheim Orange will not succeed this is a very good substitute.—E. M.

COCKPIT.

How seldom now do we see this Apple. In Yorkshire it is a great favourite as an orchard tree on grass, invariably giving a full crop of fruit of medium size. The skin is green, changing as it ripens to a greenish-yellow, with a faint tinge of orange next the sun, covered all over with small russet dots. It is an excellent cooking Apple, and a free grower.—E. M.

CHATLEY'S KERNEL.

This Apple does not appear to be so generally known as it ought to be considering its many qualities. The tree is an excellent bearer under almost any conditions; newly planted trees give a full crop the same year. The colour of the fruit is rather peculiar, is deep red, having small spots on the surface, which renders it attractive and distinct. Its keeping qualities are of the best.—E. M.

PEASGOOD'S NONESUCH.

We are not, in judging Apples, much in the habit of applying to kitchen sorts any other test than that of size and beauty. Hence it will probably always be the case that Peasgood's Nonesuch, without doubt the handsomest, nay, the most beautiful of all our large Apples, will long take a prominent place in kitchen collections. Were it a question of cropping, quality, and keeping pro-

perties we should probably select New Hawthornden or Lane's Prince Albert in preference. Peasgood's Nonesuch is a light, soft, and somewhat fugitive Apple, generally done by the end of October. It is not a great cropping variety like Stirling Castle or Frogmore Prolific, or indeed will it compare with scores of smaller though good kitchen sorts. The tree, too, is a spreading grower. However, we cannot get away from the wondrous size and beauty found in the fruits. All the same I should not advise that it be planted largely, especially for purpose of profit.—D.

AMERICAN MOTHER APPLE.

AMONG high-class varieties that come in so well for dessert purposes, American Mother is one of the best. It is just in season now; flesh of a yellowish tint, soft, juicy, and exceedingly pleasant, with a fine flavour. The fruits are roundish, conical, almost egg-shaped, and colour finely on the side next the sun. We have not many American sorts that are high class, but this is one that merits general cultivation. It has done remarkably well this year. American Mother and King Harry, certificated the other day, are valuable October Apples. There is an English Mother Apple also, less conical in form, hardier, and rather later. The tree a very strong grower, and crops well when in years. If good October varieties be grown for dessert the later and better keeping sorts need not be poached upon until November and through the winter.—A. D.

BAUMANN'S RED REINETTE.

I NOTICED several young trees of this Apple in Kent a few weeks ago that were bearing heavy crops of good sized well-coloured fruit. It seems to be a good bearer in a young state, and from its appearance I consider it will prove a valuable sort for market purposes, also a very useful variety for the private grower.—W. H. DIVERS, *Ketton Hall Gardens, Stamford.*

APPLES FOR LOCALITIES.

TIMELY, interesting, and may be turned to most profitable account are the notes on Apples which are now appearing in the *Journal*. Discussion is invited, and if readers will give lists of Apples known to succeed in their different localities, a good work ought most certainly to be accomplished. This, to my mind, is the one thing essential, and will answer better than saying that a certain variety will only succeed in a certain kind of soil, when, perhaps, the next issue may contain a note from some correspondent giving quite an opposite view. I am fully convinced that there is much unsuccessful culture carried on through the buying of poor stunted trees which have been planted in thick rows, and have had no attention paid to them beyond, perhaps, a slight shortening of the shoots. Perhaps they are at last sent to some auction room, and there sold as bargains to persons who in a short time have reason to regret it. There is nothing like purchasing good, sound, healthy trees, and we have no cause for complaint when we can buy such trees for a few shillings each from some of our best nurserymen—trees which have been subjected to a proper system of culture by persons who thoroughly understand their wants, and I would advise all who are ordering soon to bear this in mind.

I will now speak of a few varieties which are always sure bearers here, six miles from Liverpool. Our soil is about 18 inches to 2 feet 6 inches from the solid clay, not too well drained, and very wet and cold in the winter time. Keswick Codlin, which, I believe, was the first one mentioned in the discussion, never fails to bear a good crop, and is this year better than ever. Lord Suffield, from trees five years old up to thirty years, has never failed, and the fruit is very fine. Hawthornden is equally good. Stirling Castle, is a prodigious cropper and the fruit fine. Cellini is very good. The Queen, although a small tree, has been good. Ecklinville, Warner's King, Mère de Ménage, Yorkshire Greening, Golden Noble, Brabant Bellefleur, and Beauty of Kent, the latter bearing an enormous crop, are all excellent midseason varieties. Blenheim Orange is very fine every other season, and if the tree is not pruned closely there is always a crop. In the later varieties are Tower of Glamis, Flanders Pippin, Bedfordshire Foundling, Betty Geeson, Lane's Prince Albert, Dumelow's Seedling, Northern Greening, Alfriston, and Norfolk Beefing, all excellent. Of dessert varieties, Mr. Gladstone, Irish Peach, Kerry Pippin, Ribston Pippin, Cox's Orange Pippin and King of Pippins, the old Nonpareil and Scarlet Nonpareil, Reinette du Canada, Sturmer Pippin, and Court Pendu Plat are first rate. I may mention that all the above are grown as bushes or standards, but Cox's Orange, Sturmer Pippin, and Scarlet Pearmain are excellent on walls.

Regarding the paragraph headed "A Woman's Choice," I can only say that it is an excellent one, and as grown here Stirling Castle is just as heavy a cropper, and gives us a longer succession than Ecklinville, and therefore should prefer it.—R. P. R.

SIXTY YEARS OF HORTICULTURAL PROGRESS.

(1760—1820).

(Continued from page 163.)

DR. ERASMUS DARWIN, ancestor of a man destined to become still more famous than himself, certainly far more philosophical and acute in observation, became known to gardeners towards the end of the last century by some books he published, in which fact and fancy were curiously mingled. Apart from his novel views concerning the way in which, as he thought, all living things were formed, he posed as one who put the art of gardening in a new aspect, because he threw upon it the light of imagination, and showed that poetry might lend a charm even to the humblest vegetables. It may have been that his speculations in verse did, for a time, help to cheer gardeners, who were passing through a rather gloomy crisis just then, but according to some critics the chief good he did was to afford some a hearty laugh. Even his personal preference for the Cabbage tribe could be put into melodious verse. After referring to the liking others had for Lettuces, Cucumbers, Asparagus, Artichokes, Peas, and Beans, he delineates his own partiality thus:—

"This boon I ask of Fate: Where'er I dine,
O! be the Proteus form of Cabbage mine;
Kale, Colewort, Cauliflower, or soft and clear,
If Broccoli delight thy nicer ear,
Give, rural Muse! the culture and the name
In verse immortal to the rolls of Fame."

By profession a physician, Erasmus Darwin was naturally led from the study of medical plants to the consideration of various species growing here and abroad, their uses, and modes of propagation. He had been, for some years before, a contributor of verses to magazines; but it was not till 1781 that he published his "Loves of the Plants," consisting of two parts, with sundry notes and observations, a poem which had a good deal of popularity, though it was successfully parodied by the author of the "Loves of the Triangles." A much higher flight was attempted in his "Zoonomia," meant to explain the origin of animals and plants on the theory that all were produced from the changes of irritable fibres. This appeared in 1796, and five years later came a quarto of 600 pages on "The Philosophy of Agriculture and Gardening," but it did not gain any attention, perhaps owing to its diffuseness. He also wrote a pamphlet on the drainage of marshy land, and on an improvement in the drill plough. His appearance was so jovial that he might have passed for a farmer rather than a doctor; but he stammered painfully.

There were some gardeners, whose names have been well nigh forgotten by this generation, to whom horticulture was indebted, as they gave their experience in print on subjects they had well studied at a time when direct intercourse amongst workers was often impeded through obstacles now unknown. Thus, there was Weston, who first made an extended series of observations on the methods practised in the most successful market gardens and nurseries of London. Then he published towards the end of the century his "Gardeners' and Planters' Calendar," containing cultural directions arranged in the months, and also suggestions for improvements in raising trees and shrubs. Meader, gardener at Sion House, brought out a work of a somewhat similar nature, with an appendix on the new plans of forcing Grapes and wall fruit generally. Speechly, for many years in the employ of the Duke of Portland, broke new ground in his treatise published at York upon the "Culture of the Pine Apple and the Management of the Hothouse," since he took up minutely the subject of the various insect pests occurring in houses, and pointed out how they should be dealt with. A German named Græffer, who came over to a situation in the Apothecaries' Garden, Chelsea, and afterwards joined Gordon in the Mile End Nursery, prepared about 1790 a very elaborate catalogue of perennials suitable for outdoor culture, with a list of selected annuals appended. Both in Scotland and England the works of Walter Nicol, jun., whose father was a designer of gardens in the north, became standard books of reference. His "Forcing Gardener," illustrated, appeared in 1798, and he was on a tour seeking information to complete his last volume, the Planters' Kalendar, when he died suddenly. This was finished by Sang, and published in 1811.

Several medical men besides Darwin devoted themselves in their leisure time to horticultural pursuits and gave the public some of their new ideas; Dr. Anderson, for instance, who, after cultivating land extensively in Aberdeenshire, came to Isleworth, near London, where he put up some hothouses on a plan of his own, the heat being derived entirely from the sun, and artificial warmth was dispensed with, but his patent was a failure. Much information was contained in his six volumes, entitled "Recreations in Agriculture," &c., which was rather autobiographical. Another physician,

Dr. Falconer of Bath, was a great student of horticultural history, and compiled an outline, published in 1789, of the methods recommended by early authors, with notes on the gardens of the ancients. He also wrote on the diseases to which gardeners might be specially liable, and how these might be warded off or speedily cured. Divines came forward sometimes with new proposals, like the Rev. Phillip Le Brocq, who advocated a method of training all sorts of fruit trees near the ground; a hint regarding this, however, had been dropped by Lord Bacon centuries before. Haworth, the well known entomologist, was an amateur in gardening, and he published a list of the species of Crocus and Mesembryanthemum, adding instructions for their culture.

Great progress was made in the culture of the Vine during the sixty years of George the Third's reign. The old gardeners had not been careful in preparing suitable soil for their borders, and several good composts were devised, as by Griffin of Woodhall, who received, it is said, the first medal awarded to a Grape grower. He used a mixture of one part of old manure, one of brick or lime rubbish, and two of loam, laid upon a subsoil which would drain well. In his very productive vineries he had a single shoot led up under each rafter, getting his fruit from the side spurs, which he had cut down to single eyes every winter. Mr. Seton, an amateur of Stamford Hill, noticing that the Vine produces the most vigorous shoots at its extremities, while the lower parts were nearly unproductive, adopted a new plan of horizontal training, by which the whole of the fruit-bearing part of each Vine was very nearly on the same level. He thereby succeeded in getting an abundance of Grapes from the long fresh shoots, also from the old wood. This was somewhat similar to the succession method of pruning advised by Abercrombie and others. Forsyth advocated laying the shoots in a serpentine form, and McPhail showed that the old zig-zag training, which might do for walls or trellises, should not be followed in houses. He opposed too early forcing, but Nicol was introducing the practice of making a start in autumn, which he found usual amongst the Dutch growers. Apparently, it was from Flanders that the practice was introduced, which became very popular, of covering Vines upon walls with temporary frames of glass, stimulation being given by stable manure. The usual way of obtaining new Vines was by cuttings, though Speechly preferred to get them from eyes, and layering found great favour amongst Scotch growers. Peaches were now frequently forced in houses. Dwarfs, two years trained, were usually introduced in November; these were pruned during the spring, fan-training being mostly adopted.

Forcing Cherries is a less important matter than it used to be, owing to the free supply of foreign fruit at present, but the Cherry house gave much trouble to Georgian gardeners, their failures sometimes arising from the neglect of sufficient ventilation, and Nicol proved that air should be freely admitted in February. He, with M'Phail, recommended for forcing the Morello and the Mayduke. It was usual to have a trellis at the back for wall-trained dwarfs, and rows in front of dwarfs and "riders" mixed. Figs in pots were often placed in Cherry houses, but they required more heat than was usually given there, and Neill succeeded in getting large crops from Figs planted under the shade of Vines. Peach houses, for affording supplies of Peaches and Nectarines in June, had greatly increased in number at the beginning of this century, the crowding common in the old houses being avoided, the temperature better regulated, and the suggestion of Knight adopted that the air and sun be at times freely admitted to the fruit while maturing.—J. R. S. C.

FUNCTIONS (AND WEIGHT) OF VINE LEAVES.

HAVING read the very interesting and instructive articles in the *Journal of Horticulture* on the "Functions of Vine Leaves," I take the liberty of forwarding you samples of leaves produced by Vines that were planted 1st March, 1891, having been previously cut down to 12 inches in length. They made good wood, but were not fruited last year. This year they were cut down to the bottom of the rafter. The vinery was closed 20th February, and growth started strongly. I left from eight to ten laterals on each Vine from the ground to the bottom of the rafter.

From the seven Vines we had fifty bunches of Grapes, ranging in weight from $\frac{3}{4}$ lb. to $5\frac{3}{4}$ lbs. One Vine produced 23 lbs. of Grapes. The bunches quite touched each other, being only from three and four joints or eyes from the cane, which showed them to have been well ripened. The first fruit ripened on the 10th of July. The vinery has a western exposure. The Vines were managed on the close-stopping system advocated by Mr. Iggulden. I do not know of any other way by which you could produce better foliage.

Good leafage is of primary importance, because the higher the

development of foliage the more perfect will be the elaboration of the sap and its assimilation by the Vine. I adopted the system of stopping Vine laterals at the bunch as the result of observations made during the cultivation of Melons and Cucumbers for the last ten years. I have found that both of those fruits (for in this reference we may call the latter a fruit) swelled more quickly and with greater certainty when stopped at the fruit, than when one leaf was left beyond them in the orthodox way. As regards Cucumbers, the plan enables you to take double the quantity of fruit off a given space, and does away with the necessity for thinning the fruit, as they come in the proportion the plant can support. There is no wasted energy so to speak, as the first fruits are half grown before the second one appears.

I may state that the girth of the Vines from which the leaves were taken are at 2 feet from the ground, $3\frac{3}{4}$ inches, at 9 feet from the ground, or 7 feet up the rafter, $2\frac{3}{4}$ inches.—JOHN SWAN, *Gardener to A. L. Holmes, Esq., Mansefield, Kilmalcolm, Renfrewshire.*

[The Vine leaves sent by our correspondent are very fine indeed. We have seen many of greater expanse, but not many heavier according to their size—a much more important test of value. The leaves are a foot across, and five of them with the footstalks weighed 5 ozs., the sixth being withered weighed only three-quarters of an ounce. We once weighed a leaf taken from a young Vine at Abberley grown by Mr. Arthur Young. This leaf weighed $1\frac{1}{4}$ oz., and the average of those on the Vine would be about the same as those before us. The girth of one of the leafstalks in its thickest part, half an inch from the base, is $1\frac{1}{8}$ inch. Growers of Grapes can now measure and weigh a few fine Vine leaves, and note how far they exceed in substance those referred to. It will be observed that the rods are an inch thicker 2 feet from the ground than they are 9 feet above it. The reverse is often the case when the stems from the ground to the base of the rafters are denuded of growths. Mr. Swan evidently wastes no space. Mr. Iggulden will assume his happiest smile on reading the experience of his supporter. Mr. Dunkin will probably want to know something of the character of the crop the Vines produce next year, and not a few readers will feel a desire to hear something about the border in which Mr. Holmes' Vines have grown so well.]

EVENTS OF THE WEEK.—The ensuing week will not be a particularly busy one. The National Chrysanthemum Society's Exhibition, which opened at the Royal Aquarium, Westminster, yesterday, October 12th, will continue to-day (Thursday) and Friday. The usual Committee meetings of the Royal Horticultural Society will be held in the Drill Hall, Westminster, on Tuesday, October 18th, when prizes to amateurs for Apples, Pears, and Grapes will be offered. A paper on "Cycads," by Mr. W. Carruthers, F.R.S., will be read at the afternoon meeting. Several sales will take place, for particulars of which see advertisements.

— THE WEATHER IN LONDON.—The present week opened dull, wet, and cold, rain falling heavily in the metropolis on Sunday morning. As the day advanced, however, it cleared, and has been bright but cold ever since, the wind being in a north-easterly direction. Several slight frosts have occurred at night. At the time of going to press the barometer is firm, and there are indications of the fine weather continuing.

— WEATHER AT LIVERPOOL.—Perhaps at no time during the whole of the present season have we been visited by such incessant rain as during the past week. The only portion of fine weather was on the Tuesday, the Monday preceding it being a pitiless downpour. Since Tuesday rain has been almost continuous, and the gale of yesterday (10th inst.) caused great destruction amongst the fruit, bringing it off the trees, although not ready for gathering. Potatoes are badly diseased, and in some places the fields are flooded. There is a quantity of corn not yet secured, and altogether the season is one which is certain to cause a great amount of suffering amongst the smaller farmers.—R. P. R.

— GARDENING APPOINTMENT.—Mr. Samuel Scott, late gardener at Rathmore, and previously foreman at Brocklesby Park, has been appointed gardener to the Hon. Mrs. King-Harman, Rockingham, Boyle, Co. Roscommon, Ireland.

— NEMESIA STRUMOSA SUTTONI.—Messrs. Sutton & Sons send us flowers of this distinct and attractive annual, as they think it will interest our readers to know that the plant flowers freely so late in the autumn. It was figured in our columns at the time it was honoured by a first-class certificate, and we suspect this *Nemesia* will become a popular garden favourite.

— PERENNIALS AT CHISWICK.—A number of the later species and varieties of perennial *Asters* are now blooming in the Royal Horticultural Society's Gardens, Chiswick, where there is to be found probably one of the most complete collections of these plants in the world. They are well worth a visit from all lovers of the Starwort family. The collection of Apples has been stored in the fruit room, and as each variety is correctly named the attention of Fellows and others interested in the cultivation of the best kinds suitable for particular purposes is called to the fact. The Grapes in the large conservatory are now ripe, and the fine hanging clusters present a remarkably fine appearance.

— HARVEST FESTIVALS.—These are now the order of the day but seldom do the gardening charitable organisations derive any benefit from them. An exception, however, has been made at Shirley, near Croydon, where the Rev. W. Wilks, Secretary of the Royal Horticultural Society, is Vicar. Mr. Wilks made an appeal to his parishioners on behalf of the Gardeners' Royal Benevolent Institution, with the result that over £30 were collected at the harvest festival, and this sum, it is said, has been handed to that organisation. We commend Mr. Wilks on his thoughtfulness.

— DANIEL'S DWARF PERFECTION ASTER.—I should like to call the attention of readers of the *Journal* to this new Aster. It attains a height of from 10 to 12 inches, is freely branched, the flowers large, reflexed, and of every shade of colour found in *Asters*. The rose, pinks and whites are particularly beautiful. In my opinion this Aster will run the good old *Chrysanthemum* kind hard for first place when it becomes better known. I have both these varieties planted side by side, and the Perfection has a decided advantage over the *Chrysanthemum* in point of freedom of flowering, and is much more freely branched.—T. A., *Cirencester.*

— TRITOMA UVARIA.—Notwithstanding the number of excellent sorts now at command, there is no bolder, richer plant for lighting up autumn gloom in the garden than *Tritoma Uvaria*. For some time past a splendid bed of it has been producing a magnificent effect in the nursery of Messrs. Neal & Co. at Wandsworth. Seen from the road at a distance of 100 yards or so with an ample background of shrubs they present their most glowing appearance. The "pokers" are of a light orange-scarlet hue, and the shade is always intensified by a dark background. When planted alone they are hardly so striking, though by no means devoid of beauty. Bold clumps in large mixed borders are very fine.—WANDERER.

— LONG RUNNER BEANS.—So much did Runner Beans suffer from the frost of September in many places that they have ceased to crop. I was therefore unprepared to see such splendid samples of Beans at Earl's Court as Mr. Waite and Mr. Friend had in their collections, whilst Messrs. Wilkins and Lyc had none. Mr. Waite's sample of Prizewinner was one of the best I have ever seen, and as an example of their quality I asked for and obtained one Bean, the which I found on reaching home to be exactly 10 inches in length, perfectly straight, narrow, and handsome. I made a rough tracing of it for future reference. I hardly think it will be possible to excel such a sample. The large Giant Runner Beans range from 1 inch to $1\frac{1}{4}$ inch broad, that is too coarse. The one in question was just three-fourths of an inch broad.—A. D.

— RHYTHM IN PLANTS.—Some interesting experiments in the artificial production of rhythm in plants have been exhibited by Francis Darwin and Miss D. F. Pertz, says a scientific journal. The plant under observation was fixed to a spindle, and by a clockwork escapement was given a sudden semi-rotation at the end of every half hour, which caused a series of alternations of the direction in which the plant tended to curve, through the influence of either light or gravitation. This induced a rhythmic state closely resembling the periodicity set up by the alternation of day and night. Stopping the clockwork gave a remarkable result. The plant continuing to curve with an acquired rhythm as before, having, in fact, learned and remembered the half hour period. This is precisely similar to certain natural rhythms, such as the regular opening and shutting of flowers for a short time after being placed in constant darkness.

— A PARK AT RAMSGATE.—A new park has recently been opened at Ramsgate. This is situated in the Ellington suburb, and together with the mansion was purchased for £12,400.

— NEW PARK AT ST. ALBANS.—Sir J. B. Maple, M.P., has recently intimated his intention to present twenty-four acres of land to the City of St. Albans to be made into a public park and recreation ground, and it is stated that the Corporation has now decided to accept the generous offer.

— PEAR DOYENNE BOUSSOCH.—Mr. Woodward, the well-known Maidstone exhibitor of fruit, showed some very fine specimens of this Pear, gathered out of doors and perfectly ripe, at Earl's Court on October 6th. It is a large and luscious Pear, not far removed from the front rank as regards flavour if eaten directly it is ripe.—W.

— MAGNIFICENT VEGETABLES.—Mr. Pope of High Clere, Newbury, has exhibited many grand specimens of his skill as a vegetable grower, but in the "trophy" arranged by him at Earl's Court last week he fairly excelled himself. It may be doubted whether so magnificent a collection has ever been put together by one grower. His Beet, Cauliflowers, and Leeks were superb.

— A MILLIONAIRE'S GARDEN.—It is stated that Mr. Jay Gould, the well known American millionaire, has a passion for gardening, and at his residence on the banks of the Hudson River he has a remarkably fine collection of plants. An authority says that Mr. Gould has recently instructed an American firm to erect a new conservatory at the cost of about £20,000.

— ANTS ON OAK TREES.—Dr. E. Rathay states that the galls of *Cynips calycis*, produced on *Quercus pedunculata*, attract, by their viscid secretion, a number of small ants, which he believes to be advantageous to the tree in killing quantities of caterpillars and other insects which are its natural enemies. He illustrates the value of this protection by the statement that the inhabitants of a single ants' nest may destroy in a single day upwards of 100,000 insects.

— AN AMATEUR'S POTATOES.—In many respects one of the most noteworthy exhibits at the recent Potato Show was the collection from Mr. E. Chopping of Milton, near Sittingbourne. He had not merely a dish or two of gigantic tubers, but seventy dishes of as smooth, clean, and even produce as ever graced a table. This is a better example of common-sense Potato growing than half a dozen heaps of deep-eyed monsters. Evidently the Judges thought the same, for they awarded a silver-gilt medal. They would have appreciated the collection still more had they been aware that Mr. Chopping is an amateur cultivator who has taught himself how to grow Potatoes, and attends to them in the time spared from a business quite distinct from horticulture. A silver-gilt medal is a high honour for a working amateur to win, but it was well deserved.—W. P. W.

— PYRETHRUM ULIGINOSUM.—This is a most useful as well as showy hardy perennial border plant. It grows from 4 to 5 feet high, according as the soil is poor or rich, and produces with great freedom large white single flowers with yellow centres, many of which measure 4 inches in diameter. The flowers of *P. uliginosum* are most useful for filling vases for the embellishment of rooms during the months of September and October. Stems 4 or 5 feet long furnished with dozens of flowering branches may be used entire in large trumpet-shaped glasses, intermixed with similar spikes of *Aster novæ-angliæ rubra*, *A. formosissimus*, rosy purple; *Rudbeckia Newmanii*, and *Helianthus giganteus*; or the branchlets may be cut with stems from 20 inches downward as desired. The plant is easily increased by division of the roots, and it will thrive in any light soil of average fertility.—H. W. W.

— MUSCAT OF ALEXANDRIA GRAPE WITHOUT HEAT.—In a lean-to house provided with pipes, but which has a boiler out of repair, I have a Muscat of Alexandria that has carried six fair-sized bunches this year. As I have had no heat from the pipes since early in the summer of last year I did not expect these bunches to come to much good, but I was agreeably surprised, for the berries are a fair size, and I cut four bunches quite ripe on 23rd of September. The other two, which were rather exposed to the sun, and being badly scalded were but sorry looking things, but the berries which escaped were ripe nearly a fortnight earlier than the rest. A Gros Colman has four bunches of fine berries still hanging, though only partly coloured, but, unfortunately, the berries keep cracking. I have not seen a Muscat of Alexandria grown in an unheated house before, so fully believed it would not ripen its fruit.—H. S. EASTY.

— STRAWBERRIES IN THE AUTUMN.—Occasionally Strawberry plants bear a crop in the autumn, and it is stated that some ripe fruit was gathered last week from gardens at Bekesbourne, near Canterbury, and in the neighbourhood of Ashford. The fruit was luscious and of full size.

— HOPS IN KENT.—The Hop harvest in Kent, which was not finally brought to a termination until the end of last week, will be noted for phenomenally large growths secured by a few of the most successful planters. One of these, an East Kent grower, is reported to have obtained as many as 4000 pockets, probably the largest individual growth of the season.

— FOREIGN FRUIT.—The first American Apples of the season arrived in London last week, and the majority of the fruit are beautiful in colour and of fine size. Californian Peaches of large dimensions are also plentiful in the London markets, but the flavour of the fruit is somewhat disappointing, being decidedly inferior to a good English grown Peach.

— DAHLIAS IN SCOTLAND.—We see by a note in the last issue of the *Journal of Horticulture* that Dahlias are cut down in the South by frost. We send you a few blooms of new and recently introduced varieties, to show that here in the West of Scotland we are still untouched by frost, although rain has fallen for six weeks almost continually.—DOBBIE & Co.

— FALLEN LEAVES IN ORCHARDS.—To rake up and burn the fallen leaves in the orchard or to put them in the manure heap, says an American contemporary, will lessen the liability of the spreading of fungus diseases, and the same is true of all other plants. Where fungus is very troublesome in any season such measures may be necessary to prevent its returning the next year with increased power.

— VIOLAS IN AUTUMN.—Beds of these in wayside gardens remind passers-by of the exceptional value of the plants from their long period of blooming. If cultivators will take the slight trouble to pick off the seed pods as they form, the plants flower on unweariedly for many weeks, after those which have been exhausted by early seed-ripening have lost their freshness and beauty. Violas are wonderfully cheerful at the dull season, notwithstanding their lowly growth, and their good qualities are not to be exhausted in the praise of a few lines.—P.

— THE PRINCES' STREET GARDENS ARBITRATION.—The proceedings in the arbitration between the Corporation of Edinburgh and the North British Railway Company as to the price to be paid by the latter for the ground taken by them in Princes' Street Gardens was resumed on Wednesday, October 5th, in Dowell's Rooms, George Street. The case for the Corporation, who claim a sum of £150,000, was continued, and the witnesses examined for them were Mr. Washington Browne, Edinburgh, and Mr. Alexander Frew, C.E., Glasgow; also Mr. James Watt, of the firm of Messrs. Little & Ballantyne, nurserymen, Carlisle, and Mr. John Methven, of the firm of Methven & Sons, nurserymen, Edinburgh. Both the latter gentlemen spoke principally on the question of amenity and on the laying out of the ground.

— AN AMERICAN OPINION OF ENGLISH GARDENS.—A distinguished American landscape gardener, who has been sojourning among us after a long absence, records his impression of our parks and gardens. He did not admire the famous terrace at Chatsworth, but found the late Sir Joseph Paxton's work in the Duke of Devonshire's pleasure ground more interesting than of old. This is attributed to growth; for this authority lays it down as a rule that justice cannot often be done to a landscape gardener's design in less than fifty years after the work has been initiated, nor then unless it has been in the hands of one in sympathy with Nature. Mr. Olmsted, the gentleman in question, is of opinion that the selection and disposition of trees and plants, the modelling of surfaces and the arrangement of roads and walks and architectural conveniences, with a view to pleasing general effects of scenery, have been of late much confused and often lost sight of in efforts to provide brilliant local spectacles, to display rarities, curiosities, and luxuries of vegetation, and to exhibit masterpieces of horticultural craft and costly garden bric-à-brac. Vast numbers of trees have, he says, been planted without knowledge or soundly formed anticipations of what they will become. Our visitor notes with satisfaction that since his last visit there has been a decided abatement of "the bedding-out nuisance" and "of all the garish and childish fashions that came in with it."

— **TWICKENHAM HORTICULTURAL AND COTTAGE GARDEN SOCIETY.**—The autumn Show of this Society will be held in the Town Hall, Twickenham, on Tuesday and Wednesday, November 15th and 16th. A liberal schedule has been prepared, prizes being offered for fruit, plants, vegetables, and table decorations, in addition to Chrysanthemums—the principal feature. Mr. J. J. G. Pugh, 2, Heath Road, Twickenham, is the Secretary.

— **A NEW VIOLA.**—Mr. G. McLeod of Chingford, a well-known raiser of Violas, sends us blooms of a new variety named J. B. Riding. The flowers are large, of good substance and perfect symmetry, while the colour is quite a new break. The top petals are of a rich purplish maroon, a puce tinge in the bottom petal, and a bluish centre with a deep yellow eye. It is a splendid variety, and in due course will doubtless become a great favourite.

— **AILSA CRAIG ONION.**—It would be interesting to know the true character of this Onion. From a packet of seed which I sowed last spring I have two distinct varieties. The majority of the bulbs are globe-shaped, the others are flat, a good deal the shape of Giant Zittau. Both are large handsome Onions, but I doubt whether they will keep so well as some other varieties grown by the side of them. Perhaps Mr. Deverill, or some of your correspondents who have grown this Onion, can explain which of mine is the true variety.—R. M.

— **MONTBRETIA.**—This Iridaceæ Cape bulbous plant is an exceedingly showy and useful occupant of the herbaceous border. The branching stems attain to a height of about 2 feet, and the drooping tubular flowers vary in colour from clear yellow to orange-scarlet, and show to great advantage above its pretty grass-like foliage. The Montbretia, or Tritonia as it is now called, does best in a well-drained sunny border. A compost consisting of three parts light loamy soil and one of leaf mould will suit its requirements admirably. Owing to its habit of growth, and the colour and form of the flowers, it is most useful for cutting purposes during the months of August and September. The varieties M. Crocosmæflora, M. Etoile de Feu ("Star of Fire,"), M. Gerbe d'Or ("Golden Sheaf,"), M. Potsi, orange and scarlet, and M. pyramidalis, apricot salmon, are among those most deserving of culture.—H. W. W.

— **THE WEATHER LAST MONTH.**—September was very changeable, but only a small quantity of rain fell up to the 20th. It was, however, mostly wet weather after, but we had nine bright days, four of which were either wholly or partly clear. Wind was in a westerly direction for twenty-seven days. We had a sharp frost on the night of the 17th, which did much damage to tender plants in exposed places, but did not kill them. Barometer has highest, 30.35 on 5th and 6th; lowest, 29.44 on the 30th. Total rainfall, 2.39 inches. Rain fell on thirteen days, the greatest daily fall being 0.79 inch on the 20th. Highest shade temperature was 71° on 13th; lowest, 32° on 18th; lowest on grass, 24° on the 18th. Mean of daily maximum readings, 63.60°; mean of daily minimum, 45.60°. Mean temperature of the month, 54.60°. The garden spring ran 20 gallons per minute on the 30th.—W. H. DIVERS, *Ketton Hall Gardens, Stamford.*

— **OUTDOOR PEACHES.**—A few weeks ago I saw some notes on outdoor Peaches in the *Journal*, so I thought my experience might be of interest to readers. I have but little wall space, or I should grow many more Peaches and Nectarines in the open air. As regards varieties, Alexander always ripens in July on a south wall, but it is a somewhat shy cropper. The fruit, however, is of good flavour and excellent colour. Hale's Early follows on an east wall. This variety ripens about middle of August. This is also sometimes a shy cropper, but to make up for it the fruit is large and beautifully coloured when the crop is thin. Dr. Hogg on a south wall comes in a few days later, and is, I think, by far the best outdoor Peach. It never fails to carry a heavy crop. It is a vigorous grower; the fruit is large and well coloured, and the flavour first class. I have it also on an east wall, where it is ten days later, and it does equally well there. Grosse Mignonne on a south wall comes in about beginning of September with medium-sized fruit of good flavour. It does not do well with me, being very weakly. Alexandra Noblesse, a pale fruit without any colour, on a south wall only ripens with me at end of September, and is a very shy cropper. In an unheated lean-to house this variety, however, crops better than outside, the fruit being large, pale, well flavoured, and of a beautiful appearance. Under a wall cover I have Sea Eagle, which does well, crops immensely, and is beautiful in appearance, but I do not think much of it as regards flavour. It ripens about end of September.—H. S. EASTY.

— **A LARGE PEAR.**—I was shown a very fine fruit of Pitmaston Duchess a short time ago at Barham Court by Mr. Woodward. It was weighed in my presence, and proved to be 1 lb. 11½ ozs. As it had been gathered for several days, I have no doubt it originally weighed 1½ lb. or more. I omitted to take the measurement of it, but it was certainly the finest Pear I ever saw grown out of doors in this country.—W. H. DIVERS, *Ketton Hall Gardens, Stamford.*

— **OLD READERS.**—In your report of the Royal Horticultural meeting last week my name is wrongly spelt as "Horley," gardener to W. E. Hall, Esq., instead of Kidley. Although I may be unknown to you your paper is very well known to me. I have been a reader since 1871, and I am going in for the first pension that you give away for old readers.—SAMUEL KIDLEY, *Yeovil.* [We suspect if a pension were offered to the oldest reader many stronger claims would be "put in" than by our correspondent, but the longer he continues reading, which we hope will be many years, the stronger his claims will eventually become. We have pleasure in making the suggested correction.]

— **SURPLUS BEDDING PLANTS.**—It has been officially announced by the London County Council that the surplus bedding plants at the metropolitan parks and public gardens under their control will be ready for distribution on or about October 21st. Applications for the same should be made early to the superintendents of the respective parks. It is also stated that the Commissioners of Her Majesty's Works and Public Buildings intend to distribute, this autumn, among the working classes and poor of London, the surplus bedding plants used in Hyde and Regent's Parks, and in the pleasure gardens at Hampton Court.

— **THE CHISLEHURST GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.**—The members of the above Association held their second annual meeting on Tuesday, October 4th, a good number of members being present. The balance sheet for the year shows that the Association is in a most flourishing condition, although entirely supported by members' subscriptions. Officers for the ensuing year were elected, and various alterations of rules made. Several papers on gardening subjects were promised for the ensuing session. Meetings are held weekly on Tuesday evenings, from October to March inclusive.

— **MICHAELMAS DAISIES FOR BEDDING.**—I was glad to see the excellent suggestion thrown out by Mr. Dewar in his lecture on Michaelmas Daisies at the Drill Hall that these useful plants should be more frequently employed for bedding than is now the case. For several years one of Mr. Graham's most beautiful beds at Hampton Court was composed of Madame Desgranges Chrysanthemum surrounded by a broad band of Aster Amellus bessarabicus, and it may still be maintained, for I have not had an opportunity of judging personally during the past three years. But one thing is indispensable, the plants must be of such a character as to display a well-clothed base, for if they were of the description too often seen—namely, huge, top-heavy bushes with prominent brown stems, they would be unsightly rather than ornamental. The best way of getting plants well feathered with leafage is to raise them from cuttings, making use of the young shoots when they have pushed about 3 inches above the soil. These will give plants of a short-jointed, sturdy nature, whereas taller shoots would develop the same character as that just deprecated.—WANDERER.

— **A HEAVY CROP OF GRAPES.**—Those interested in the crops Vines are capable of carrying would, I am sure, be highly gratified if they paid a visit to the Sunny Hill Vineries, three miles from Derby, belonging to Messrs. Innes & Co. The Vines are only young, but I am assured on good authority that they have borne heavily from the first. This is almost proved by a visit, for a house of Vines two years old was carrying about eight fine bunches on each Vine. All the houses but one are span-roofed, about 85 feet long each and 22 feet wide, running north and south. The Vines are planted 2 feet apart, and are carrying twenty-one or twenty-two bunches each on an average. The houses are high, and the Grapes as thick as they can conveniently hang. The bunches are large, the berries very fair, and the Grapes had every appearance of colouring sufficiently well to find a ready sale in the market. With the exception of one house that is mixed with Alicante, Gros Colman is the variety grown. The lean-to house is filled with Muscat of Alexandria, the temporary Vines being Gros Colman; and here the crop, which was partly cut, was extremely heavy, yet the Muscats were good. Mr. Innes, unfortunately, was from home when I called, and not having made any notes, if I am wrong in any little particular I hope he will correct me.—WM. BARDNEY.

— THE LATE MR. C. H. SHARMAN (CARTER'S).—Had I been in London recently I might have been less surprised, as well as grieved, at seeing in your last issue the death of this much respected gentleman. Would you kindly allow a voice from Ireland to mingle with yours and that of the eminent firm (Carter's), that I am personally aware he so strenuously endeavoured to ever and always place first on the road to success? He was a man of wonderful business capacity. Whenever I went to London I generally called to see what new improvements—what additional achievements—had been added to the establishment in Holborn. I often waited in the office and casually observed him giving orders to two shorthand clerks at once while superintending some dozens of others, and ever and anon giving telephone orders all over London. If he had any quality more than another it was punctuality—a specific that I am not ashamed to confess both the writer and his countrymen might learn many things from our English friends. I once made an appointment with him to go down to Essex to see the seed farms, and was delayed five minutes at the Arundel. I met him on the steps, but only to receive a lecture on my want of punctuality. He was a whole-hearted servant of his firm, its wants and appliances, so none need be surprised at their regret of his premature demise. I am sure other voices will re-echo my regret to his bereaved family from the Green Isle.—W. J. MURPHY, *Clonmel*.

— SUMMER-PINCHING FRUIT TREES. — Mr. Davis, the able gardener at Manresa House, Roehampton, is so excellent a fruit grower that all his opinions are entitled to respect. This being so it may not be without interest to mention that he is not a believer in the summer pinching of fruit trees, and is able to lend emphasis to his opinions by pointing to trees laden with fruit, and with bold fruit buds showing for another year. In looking over the trees, however, the secret of their success and of the non-necessity of summer pruning is quickly apparent. The branches are trained so widely apart that air and light have the freest access to them. The growth is annually matured, and good crops follow. The free-fruited character of such trees is a natural check to exuberant growth, hence the necessity for summer pinching is obviated. Were trees to fall under Mr. Davis's care of which the main branches were closely packed together by earlier mismanagement, it is well within the bounds of possibility that he might find a system of summer pruning desirable if not absolutely necessary.

— PEACH SALWEY.—In the gardens at Manresa House, where fruit of all kinds, and particularly Vines, is so splendidly grown by Mr. Davis, a tree of this good Peach on a south wall is now carrying an excellent crop of very fine fruits. They will form a welcome supplement to the indoor crop.—P.

— POTATOES AT EARL'S COURT.—Owing to our having to go to press a few hours after the great Show of Potatoes and fruit at the International Horticultural Exhibition opened last week, we could hardly do justice to the magnificent display of tubers made by Messrs. Sutton & Sons, of Reading, and other exhibitors. The collection of Potatoes shown by Messrs. Sutton & Sons was, perhaps, one of the finest ever brought together. It consisted of close upon 4500 tubers in 222 varieties, the majority of the sorts having been introduced by the firm. The tubers were remarkably clean and bright, and of perfect symmetry, affording evidence of what can be done by judicious selection and careful cultivation. A large number of seedling Potatoes were also shown by Messrs. Sutton. Mr. R. Dean, Ealing, amongst others likewise staged a collection of Potatoes, for which a bronze medal was adjudged, a similar award going to Messrs. Harrison and Sons, Leicester, erroneously printed "Davidson & Sons" in our report last week.

— EVAPORATED FRUIT.—By no means the least interesting of the exhibits at the International Horticultural Exhibition last week was a case of evaporated and conserved fruit from Mr. Trotter, gardener to F. Ricardo, Esq., Bromesberrow Place, Ledbury. The specimens were displayed in small divisions, and looked tempting in the extreme. The dried fruit comprised whole, ring, and cored Apples; Green Gage, Victoria, Washington, and Orleans Plums, Apricots and Damsons. They had been treated with Mayfarth's evaporator, and judging by appearances were excellent. It would have been a wise step on Messrs. Mayfarth's part to have supplemented the exhibit with a few piles of the fruit ready for eating, at all events during the time the Show was reserved for the Judges and Press. In all probability there is a great future before fruit evaporating in this country. I have tasted delicious Apples evaporated a year before being eaten, and in winter they form a most wholesome and agreeable dish for those who have not the key of a big fruit

room in their pocket. Mr. Trotter's conserved fruit comprised Pears Plums (Washington and Victoria), and Apricots. These looked to be delicious sweetmeats; but the treatment with sugar, from which fruit should be kept free whenever possible, impairs their value for ordinary culinary purposes. Presumably, Mr. Ricardo is experimenting in fruit evaporation, and a record of the results secured would be most valuable. It will be a great gain if we can in a large measure substitute evaporated fruit for jam, which is generally less wholesome, while it lacks the full fruit flavour.—W. P. W.

— AUTUMN MAMMOTH CAULIFLOWER.—This is a product of that keen observation and selection which enterprising seed growers show in relation to vegetables in particular. It is evolved from out of the Autumn Giant, and has its special merits in being some three weeks earlier from identical sowings and plantings, and has finer and whiter heads than has that variety. I saw this growing in Messrs. Sutton & Sons' seed grounds at Reading several weeks since, when the earlier and finer character of the heads was most marked in what was a capital trial of the leading varieties. At the Earl's Court Show, where the Mammoth was found in splendid form in the leading competitive collections of vegetables, I invited the judgment of some of the leading growers, such as Messrs. Pope, Lye, and others, and they all agreed that the Mammoth was not only distinct from the Giant, but was an earlier and superior variety. Mr. Lye indeed said, "I can find no two better Cauliflowers in cultivation for summer and autumn use than are King of the Cauliflowers and the Autumn Mammoth."—A. D.

— GALTONIA CANDICANS.—Although this bulbous plant will not live through the winter in some soils out of doors, it possesses so much beauty and usefulness in the flower garden that any extra time and trouble spent are not wholly thrown away. Independently of its use in the herbaceous border this plant can be employed in a variety of ways in the flower beds, harmonising well with other things. A few years since, owing to the soil being heavy and wet during the winter, the bulbs decayed, failing to come up the following spring. My plan now is to take those up every year that are employed in the beds and put them into 5-inch pots. They are then started gradually into growth in a cold frame, and planted out afterwards where required. When new bulbs are required for the borders we pot them in the same way, and when they have made 6 inches of growth I dig out a hole in the border 18 inches deep and 1 foot wide, filling it entirely with prepared compost, such as refuse potting soil and leaf mould.—S.

— WOOLTON GARDENERS' MUTUAL IMPROVEMENT SOCIETY.—At the autumn conference of the Lancashire and Cheshire Association for the Extension of University Teaching held in the Temperance Institute, Southport, Prof. G. H. Rendall, Principal of University College, Liverpool, delivered an important address on "University Extension," and, in speaking of the necessity of continuity of teaching, referred to the Woolton Gardeners' Mutual Improvement Society in the following terms:—There (Woolton) the original demand was of an entirely spontaneous nature, and one that arose from a desire of the gardeners for more insight and intellectual knowledge of the subject of their actual life. The demand was, as he had said, spontaneous and in touch with life, and if a subject were in actual touch with life and experience it had a more permanent hold upon them than one which they might take up out of mere curiosity. This demand had developed into a course of extension lectures, thanks more especially to the two H. G.'s—Mr. Holbrook Gaskell and Mr. Harvey Gibson, who he was glad to see present; and then into a permanent Mutual Improvement Society, which had been in existence for some years. They had now their microscopic study, their fortnightly meetings, their report upon practical horticulture, which stimulated and raised the whole tone of gardening, and of the gardeners' interest in horticulture and botany. The University extension course, and that Mutual Improvement Society which had developed from it, had now become a personal and resident interest. The Society had been a courageous one, and had now, he was glad to see, disapproved of and declined to take a travelling library, preferring a permanent library of its own instead. An interesting discussion followed. On Thursday evening last the first of the winter meetings was held in the Parochial Hall, and took the form of a floral concert, the proceeds being in aid of the Gardeners' Benevolent Institution and the Gardeners' Orphan Fund. There was an excellent attendance, and a fair sum was realised. The Hon. Secretaries (Messrs. Disley and Waterman), and all those who so readily helped in many ways, are deserving of the highest possible praise.

CHRYSANTHEMUMS

CHRYSANTHEMUMS AT GORTMORE, DUNDRUM, CO. DUBLIN.

A VISIT to some of the growers of Chrysanthemums is quite as interesting in the month of December as when the plants are in full flower. This was the case with me when visiting Gortmore, the seat of J. G. Nutting, Esq., by seeing to what an extent of perfection the individual plants attain. The illustration (fig. 45) below, reproduced from a photograph, gives an idea of the plan adopted by the able gardener, Mr. E. Knowlton, for growing his Chrysanthemums for exhibition.

The border on which the plants stand faces south, and is over 100 feet long by 18 feet wide. It is covered with coal ashes, which are

MARKET CHRYSANTHEMUMS—EARLY FROSTS.

CHRYSANTHEMUMS for market are grown in such quantity that the question must often arise in the grower's mind whether the time devoted to their cultivation during the spring and summer could not be more profitably employed. To the fruit grower they are useful in many ways no doubt, chiefly as filling an awkward gap in the autumn and winter after the summer crops are over, and forming a source of income when his houses would perhaps be empty. They can be housed until their flowering season is over, too, without augmenting the bills for fuel very largely. But the markets are often glutted with them, and they are frequently sold very cheap, the percentage of profit being very low. It must not be forgotten that they require careful attention at a time when the work of the season is very pressing, and when the hands are needed badly in other ways.

But lately we had the question from another point of view for consideration. The winter quarters of our Chrysanthemums were occupied by Tomatoes, and our leading variety being a capital late setter the middle of September found us with a heavy crop of fruit, which we were unwilling to sacrifice in order to make room for Chrysanthemums. Stated briefly, it was a case of Tomatoes *versus*

FIG. 45.—CHRYSANTHEMUMS AT GORTMORE.

made quite firm, and bricks placed for the pots to stand on. There are four rows of posts, with galvanised wire strained on each row; to these the green painted stakes are tied, and not thrust in the pots, as is usually done. There are seventy-five to eighty plants in each row, all of which are allowed to break naturally, and these are tied in a regular manner to the stakes, presenting to the eye an appearance of four symmetrical hedges. The varieties are so arranged that the plants in each row are nearly the same height, the tallest being about 8 feet high. It is gratifying to note the healthy, vigorous strength, and ripeness of wood, well covered with rich green foliage, and the very few buds lost through all the recent strong winds.

Chrysanthemums at the time of my visit were everywhere on the walks, and all looked exceedingly well. When once they all are housed the display will be very fine. Last year Mr. Nutting, with the aid of his energetic gardener, took all the leading prizes at the Dublin and provincial Shows.

There are many beauties about this lovely country seat worth noting, such as the grounds, which are well laid out and planted with fine Coniferae, and in the garden Roses are a speciality. In the houses are stove plants and Orchids, too numerous to mention.—J. W. HENDERSON.

Chrysanthemums. Somewhat unexpectedly the former won the day. Previous to the 17th of September the nights had been cold, but few expected frost of sufficient severity to injure Chrysanthemums. The sharp frost on the night of the 17th or morning of the 18th found us consequently completely off our guard. All through the Lea valley the weather was more or less severe, but many growers saved their plants from injury by laying them down and covering them with mats or straw. At several places 9° of frost were registered, a temperature, of course, low enough to fatally injure Chrysanthemums.

I must add that our Chrysanthemums are badly cut up. We had several thousands exposed, out of which we shall save very few, the buds on early and late varieties being alike irretrievably damaged. We shall probably get an inferior crop from the flowering shoots lower down the stem. Certainly we are not the only sufferers, as I am informed that one large grower has 40,000 plants all more or less injured. Doubtless many that think they have escaped will form a different opinion when the flowers expand. But one thing is evident, and that is that in this district preparations will have to be made for housing Chrysanthemums in future before September is very far advanced, which will shorten a season already sufficiently brief, and be the means of making Chryse-

anthemums even less profitable than they were. Covering the plants can only be practised to a limited extent, and where the planting out system is in vogue it is almost useless. It is singular to have to record that the variety least injured is the early flowering *La Triumphante*, the earliest variety we have; *Princess Teck* and other late sorts, with their buds scarcely formed, being hopelessly crippled.—ENFIELDIAN.

CHRYSANTHEMUMS AT CHILWELL.

THIS large collection occupies the same position as in former years, three of the largest houses being filled as before, but a fourth house has been brought into requisition for seedlings and untried novelties. There are several seedlings already open of great promise, while some of the novelties bid fair to produce grand blooms. The most noteworthy are John Farwell, Emily Doone, Mrs. Lay, Mrs. J. R. Baylis, Frank Thompson, and a number of Anemones not yet known to the public.

In the show house the plants are looking well, the buds plump, and the foliage excellent. They are somewhat dwarfer than usual. Amongst the varieties now opening I noticed Wm. Tricker, which bids fair to rival, if not eclipse, the charming *Vivian Morel*. It is a brighter and more pleasing form of pink, with much broader petals, the outside ones being half an inch in width. When the blooms are fully expanded they will be very little short of a foot in diameter. *Florence Davis*, Wm. Wells (the yellow sport from *Mdlle. B. Pigmy*), W. W. Coles, Stanstead White, *Vivian Morel*, W. H. Lincoln, Miss *Esmeralda*, *Bouquet des Dames*, Mrs. Nisbett, *Gorgeous*, *Coronet*, Louis *Boehmer*, *Mdlle. Marie Hoste*, *Marguerite Marrouch*, *Golden Dragon*, and *Boule d'Or*, are the most prominent of the Japanese. Amongst the incurved M. R. Bahuant stands out as boldly as Wm. Tricker does amongst Japs, with grand solid blooms. The Queen family look remarkably well, including Mrs. R. King, which has buds of immense size; also the *Princess of Wales* family are all that could be desired, *Ami Hoste*, *Madame F. Mistral*, and *Robert Cannell* are already showing colour. There will be a grand display by the opening of the exhibition, which takes place the first week in November.—AN OLD GROWER.

CHRYSANTHEMUMS ROUND LIVERPOOL.

ONCE again the season has come round for to record a few notes on this most popular flower. I know of no plant which has such a hold on public favour, and it cannot be wondered at, for amongst the family we have varieties from which anyone, from the humblest cottager to the highest in the land, may have a selection exactly to suit them. Around Liverpool I believe we have some of the most enthusiastic growers to be found, and although many labour under considerable difficulties still they all strive to attain the highest success, and they may fairly claim credit for records in the past, and have good hopes of the future. Conditions have not changed very much here. There is one familiar face we shall miss from amongst us—the late Mr. A. R. Cox. How well he used to grow Chrysanthemums everyone can testify, and his memory will be recalled to many of his old friends when the magnificent challenge vase, presented by Messrs. Ker & Sons, Aigburth Nursery, which he won last year, comes to be placed upon the table for others to take. How he would have delighted to have been in the fray, but it is not to be. I send you a few notes on Chrysanthemums, and hope to be able to complete my list of exhibitors in a future issue.

THE HOLLIES, WOOLTON.

Although Mr. Vaughan only made his *début* as an exhibitor last year he can lay claim to some prominence by reason of his successes at Sheffield. His Chrysanthemums this year are very good, dwarf, strong, well ripened, and timed, just the sort likely to produce good flowers. The Queen family are a little taller than usual, but excellent; and the Princess type, about 6 feet high, looks very promising. Others which ought to be grand are *Avalanche*, *Condor*, *Puritan*, *Stanstead White*, *Edwin Molyneux*, *Sunflower*, *Etoile de Lyon*, *John Salter* (very fine), whilst of the newer ones are *Edwin Becket*, 3 feet high, very promising, *Vivian Morel*, 4 feet high, *Alberic Lunden*, *Florence Davis*, 5 feet, just showing colour. Mr. Vaughan thinks *Robert Cannell* will do better on the terminal bud, as it comes too early on the crown, and of a very poor colour. About 250 plants are grown.

AYMESTRY COURT.

In Mr. Osborne, the gardener, we have an unassuming exhibitor, but one who has had much success, and who grows his 250 plants in a thorough manner. This season they are taller and stronger than last year, and very well ripened considering the season—an even lot and well timed. The Queen and Princess family are in grand condition, and ought to produce some noble blooms. If the plants are strong *Robert Cannell* and *Vivian Morel* both do best on the terminal bud, and Mons. R. Bahuant seemed to be just right on the same bud, coming altogether too early on the crown. *Jeanned'Arc* is splendid. Of newer varieties the following were promising well.—Mr. and Mrs. Beckett, about 3 feet high; *Mdlle. Marie Hoste*, *Florence Davis*, and *Alberic Lunden*, 5 feet; Mr. J. Stanborough Dibbin, good habit, after style of *Avalanche*; *Violet Rose*, Louis *Boehmer*, *Lilian B. Bird*, *Gloire de Rocher*, *Beauty of Castlewood*, very good; and Noel Pragnell, the new striped Queen, looks well.

ELM HALL, WAVERTREE.

As successor to the late Mr. A. R. Cox Mr. J. Bracegirdle has had to follow a good man, but there is no fear of his not succeeding. He is persevering, and his training will stand him in good stead. He has this season 400 plants, which are throughout very promising, strong, well

ripened, and carrying well-formed buds. Amongst the newer Japanese which appear very fine are Mr. and Mrs. Beckett, Mr. A. H. Neve, *Vivian Morel*, *Gloire du Rocher*, Louis *Boehmer*, *Lilian B. Bird*, and *Mdlle. Marie Hoste*. Of the newer incurved which are very strong are *May Tomlin*, Mrs. Robinson King, Noel Pragnell, Robert Cannell, and Mons. R. Bahuant.

CLEVELEY, ALLERTON.

Although not an exhibitor, Mr. Cromwell is deserving of a place in this list. Those who have seen the long corridor filled with 600 plants, all of splendid quality, must admit that they have had a decided treat. At the present time *Bouquet de Dame* and Mons. Wm. Holmes are playing an important part in the decoration of the corridor. In the Japanese, the following are especially noticeable: *Sunflower*, very good; W. H. Lincoln, *Madame Laing*, Sarah Owen, *Condor*, A. H. Neve, W. W. Coles, *Gloire du Rocher*, grand; *Etoile de Lyon*, *Boule d'Or*, Mons. Bernard, and *Puritan*; whilst the newer are represented by *Florence Davis*, *Vivian Morel*, *Mdlle. Marie Hoste*, and *Lilian B. Bird*, all very fine. Of new varieties, Mr. and Mrs. Beckett appear to be here, as everywhere else, of good habit, and with buds of a promising character; W. Tricker is very dwarf, good foliage, and, to all appearance, will come out very fine; Louis *Boehmer* and W. A. Manda are showing good buds, but they require to be taken very early. The Queen family are fairly represented, and the Princess type especially good. Mrs. Robinson King gives every promise of being good flowers.

THINGWALL HALL, BROADGREEN.

Winning his laurels in the early days of Chrysanthemum growing, Mr. R. Foster is yet as enthusiastic as ever, and does not by any means intend to let younger growers have all their own way, judging from the fine plants which he has grown this season. Some varieties are early, but the majority are rather late, especially the Princess family. The incurved varieties other than the above look fairly well. The following are good, and look as if they will develop into good blooms: Mr. E. Beckett, W. R. Woodcock, Miss L. Cope, *Gloire du Rocher*, *Vivian Morel*, and W. Tricker.—R. P. R.

ALLERTON BEECHES.

Though rather early to form a definite opinion, still the plants promise to give a good return, especially the newer varieties. Mr. Edwards has all the latest novelties, the following having very promising buds:—Japanese: Colonel B. Smith, R. C. Kingston, W. Tricker, Mrs. E. D. Adams, *Beauty of Castlewood*, W. K. Woodcock, Mr. and Mrs. E. Beckett, *Excellent*, E. G. Hill, *Violet Rose*, Miss Lillie Measures, Mrs. George Daniels, Mrs. E. W. Clarke, *Le Verseux* (a splendid grower), H. Ballantine, and W. A. Manda. In incurved, Mrs. Robinson King, Richard Parker, May Tomlin, *Mdlle. Marie Hoste*, *Madame Gayral*, *Madame Darrier*, *Flora Macdonald*, *Sabine Mea*, and *Princess Waldemar*, the Princess and Queen types are all represented by excellent plants. Mr. Edwards has been a successful exhibitor in time past, and he is deserving of continued success.

HANLEY CHRYSANTHEMUM SOCIETY.

THE Borough of Hanley Chrysanthemum Society's tenth annual Exhibition will be held in the Victoria Hall, Hanley, on Wednesday and Thursday, November 16th and 17th. A liberal schedule has been prepared, there being numerous open and amateur classes. Notwithstanding a loss on the Show last year, the prizes have this season been slightly increased for the purpose of introducing a new feature—namely, small groups of flowers and foliage plants suitable for table decoration.

ROYAL HORTICULTURAL SOCIETY.

OCTOBER 4TH.

SCIENTIFIC COMMITTEE.—Present: Dr. M. T. Masters (in the chair); Mr. Morris, Mr. McLachlan, Mr. Blandford, Dr. Müller, Rev. W. Wilks, Dr. Scott, Dr. Bonavia, Professor Church, Rev. G. Henslow, Hon. Sec.

Bouillie bordelaise.—With reference to this preparation Mr. Morris stated that it had been thought advisable by some persons to water the soil with it, and M. Cornu, as recorded in his letter read at the last meeting, appeared to favour this view. It was, however, the general opinion of the members present that this procedure would undoubtedly sterilise the soil, and so prove highly injurious by arresting nitrification. Some further discussion arose with reference to the best manner of knowing when the bouillie was in a proper state for application, as several failures in its use had resulted from the copper salt being still present in the solution. Dr. Russell, as recorded at the last meeting, appeared to rely upon the absence of a blue colour when 2 or 3 inches in depth of the clear fluid was looked through; another suggestion, made by Dr. Müller, being the application of a small quantity of liquid ammonia. If there be any copper present the bouillie would become blue. Professor Church remarked that although all the sulphate of copper might be changed into the hydrated oxide, yet if any small quantity of the latter be left suspended in the liquid, and not entirely precipitated, the blue colour would still appear on the addition of ammonia. The simplest and most efficacious test would be to place a piece of clean iron (e.g., a knife blade free from grease) into the solution for about five minutes; then, if no film of copper were deposited on the iron it might be concluded that the mixture was in a proper condition for use. It was further added by Dr. Müller that great care is required in using the lime, as, if it were not most thoroughly pulverised

in water, portions would not come into action at all. The lime, too, must be of the best quality, and not from a quantity which had been kept for any time exposed to the air.

Prevention of Smoke and Fogs.—Mr. Michael forwarded the following report upon Col. Dulier's process for the prevention of smoke and fogs:—

"As requested by the Committee I have inspected Col. Dulier's apparatus at No. 51, Sloane Gardens. The process is especially applicable to domestic fires, including those of the ordinary English type. Shortly stated the process is as follows—viz., Steam (not under pressure) is generated in a small special boiler behind the kitchen range, and is allowed to mix with the smoke in the flue; it may be introduced either at the top or the bottom of the flue. The mixed smoke and steam does not pass through a chimney pot into the open air in the usual way, but is conducted into a condenser on the roof of the house, which receives all the flues of the house. In this condenser the steam is condensed, and falls into very fine rain, thus washing the smoke and carrying down carbon, sulphurous acid, &c., the whole being carried off by a drain. It is claimed that the condensed steam carries down practically the whole of the free carbon, and also a third to a half of the sulphurous acid when the air temperature in the open is 50° Fahr. or above, and more than a half when the temperature is lower. It does not appear that any experiments have yet been made to ascertain what proportions of the other residual products of coal combustion are carried down. The process appears to me to be simple, automatic, and well worthy of further investigation and encouragement. A wet rag placed over the discharge aperture of the condenser, where the hot air and gases escape, is not blackened and does not collect soot, and the face may be held over the same aperture without any particular inconvenience being experienced. It is further claimed that the apparatus prevents the possibility of a down draught in the chimney, and also effects a considerable saving in fuel. The present apparatus at 51, Sloane Gardens, has been erected for the purpose of experiment and demonstration only, and would, I fear, be much too costly to be enforced for general use in small houses; but it is the first made, and could probably be greatly simplified and reduced in cost. Col. Dulier would be happy to exhibit the apparatus to the Fog Sub-committee on their applying to him at 27, Sloane Gardens. The apparatus used by the chemists who tested the absorption of sulphurous acid, &c., is still in No. 51, Sloane Gardens, and Col. Dulier would place it at the service of any chemist connected with this Society who might be inclined to make further investigations."

The thanks of the Committee were given to Mr. Michael for his report.

White Ants from La Rochelle.—Mr. McLachlan exhibited specimens of the *Termes lucifugus* received from La Rochelle, the injuries caused by them having been described at a previous meeting. They are small, being about half an inch long, and in the larval condition.

Artichoke Gall.—He also exhibited a specimen of a gall, probably produced by some species of cynips.

Cladosporium on Wheat.—Mr. Plowright sent specimens showing this disease, with the following communication:—"During the last season this disease has been exceedingly common in the Wheat in various parts of England. No district has probably suffered more from it than the eastern counties. It is often present with us, but I have never seen it so abundant as this year. Whole fields were blackened by it, and many persons mistook it for Wheat mildew, with which, of course, it has no affinity. Until recently the *Cladosporium* was regarded as a saprophyte, but recent investigations show me that it can also exist as a true parasite. During the harvest the difference between Wheat mildew and the *Cladosporium* disease is very apparent, for where the last-named is present to any extent the reaping machine is surrounded by a cloud of dust. There is nothing to prevent both fungi occurring in a Wheat crop simultaneously, but, of course, the mildew is not dusty. Prof. Eriksson, of Stockholm, a few years ago called attention to the prevalence of *Cladosporium* on Rye in Norway and Sweden, and pointed out that it all occurred on the grain, and further, that when the diseased Rye was consumed it gave rise to a series of symptoms, among which were diarrhoea, vomiting, and especially derangement of nerve centres, producing dizziness and a staggering gait, like that of a drunken man. The grain of Rye being less covered by the chaff is more liable to have the fungus upon it than is the case with the Wheat. Prof. Woronin last year was called upon by the Russian Government to investigate a series of cases in which the above-named symptoms were produced by its consumption. He came to the conclusion, however, that the poisonous properties were induced rather by *Fusarium roseum* than by the *Cladosporium*, although the latter was very abundant on the affected grains. As will be seen from the specimens sent, the *Cladosporium* is especially abundant on the chaff. Such a development of parasitic life cannot but be detrimental to the Wheat affected by it, and it is probable that the *Cladosporium* has much to do with the poor yield so many agriculturists complain of this year. This is a subject into which the Agricultural Department should inquire into at once."

Cronartium ribicola.—Mr. Plowright also sent specimens of *Pinus Strobus* attacked by the æcidiform stage of this fungus, with the following communication:—"At a recent meeting of the Scientific Committee specimens of this fungus on Currant leaves were exhibited, gathered in the garden of Mr. C. G. Boyes, Oakwood House, Setch, near King's Lynn. On the 13th of August I again visited the garden and examined the Pines, in order to find if possible the branches affected by the *Peridermium*. This I was successful in doing, and herewith send one of

the affected branches. It will be seen that the mycelium of the *Peridermium* has caused hypertrophy of the affected branch. The peripheral extremity bears a sickly tuft of foliage, but the branch itself is evidently dying, although at its base it shows the enlargement due to the mycelium extending downwards. There are two trees affected about 15 yards from the Currant bushes. I have also observed the *Cronartium* on Currants in the garden at Middleton Rectory." A vote of thanks was given to Mr. Plowright for his interesting communication.

Green-fruited Elder.—Mr. Henslow exhibited sprays of this rare form of the common Elder from a tree in his garden at Ealing. The foliage differs from the common form in being darker in colour, the two halves of a leaflet approximating each other as in the Portugal Laurel, the marginal teeth being curved forwards, whereas in the common form the leaf is paler green, the leaflets are flat, and the teeth straighter. The berries of the green variety are globular with ten veins, resembling Currants, the ordinary form being oblong and black. The taste is the same in both.

ROSES UNDER GLASS.

WHERE planting is anticipated no better time could be selected than the present. Plants that have been grown in pots travel well at this season without injury or the fear of any permanent check. Having the whole of their foliage upon them, and their roots in an active condition, Roses are not long under greenhouse treatment before they become well established in the new soil, in fact sufficient to insure a vigorous growth next season.

There will be no comparison between the growth of plants planted now and those that are planted two months hence. All the attention needed will be syringing the plants occasionally after planting, and being careful not to overwater them. This is important; if the soil is made wet about them, they may fail to root into it, and start badly into growth in spring. If the soil at planting time is in an intermediate state for moisture very little, if any, water at their roots will be needed before the early months of the year, except that which they receive by syringing. As far as possible we avoid watering, and in order to do so slightly mulch the border.

In the past we have found Tea and Noisette kinds stand the winter well when planted out of pots at this season of the year, and generally do well afterwards.—W. B.

H.P. MARCHIONESS OF LONDONDERRY.

BY an odd coincidence, at the time my friend Mr. Bateman was writing to you on the subject of Messrs. Dickson's new Rose Marchioness of Londonderry, I had addressed a note to one of your contemporaries in which I described this Rose in exactly identical terms—i.e., as like a Magnolia. It is the type which strikes you at once when you see the bloom in its full development. The scent is also most uncommon. Altogether it seems to me a grand Rose.

ROSE ANALYSIS.

Your leader, signed by my friend, "E. M.," on the Rose analysis, is most interesting, and in many ways instructive. "E. M.'s" remarks are always so carefully weighed and correct that I am pleased to note the opening sentence of his first paragraph, which is in striking contrast to the inaccuracies of a writer in one of your contemporaries on a somewhat similar topic.

"E. M." emphasises my statement that the National Society's Show in July was "the most extensive ever held." I am only sorry he did not further support his remark by figures, and thereby demolish other erroneous statements which have been recently circulated.

Your correspondent proceeds then to explain the anomaly of his figures of the leading Roses being smaller than of late years by the fact of the Society having had for prudential reasons to withhold fourth prizes this year. Now what this involves is that out of some fifty-six classes (I do not count the entire sixty, as they were not all for exhibition varieties) with exhibits of from seventy-two down to six Roses, the names of what would have existed as fourth prizes, and have been taken into account in other years are now omitted, this involving the names of about 1000 Roses! I can make out the exact number easily, as you have only to count the exhibits requisite for each class and multiply by the number of classes.

I note amongst other details that "E. M." agrees with me in looking on Mrs. W. J. Grant as an improved Jeannie Dickson, but Messrs. Dickson tell me that as grown by them at Newtownards there is little similarity. I am satisfied to accept Messrs. Dickson's opinion, as they are such first-class authorities and rosarians that they are not likely to err, and, moreover, are superior to prejudice; but for our satisfaction, as rosarians in England, it would have been desirable to show these two fine Roses as grown by them and in juxtaposition next year. Whether this is feasible, now that the stock of Mrs. W. J. Grant is sold, is a question I am unable to solve, as I am not acquainted with the etiquette in such matters.

I am surprised that Madame Hoste does not figure better this year, as with me it has been superh. Allow me to make one suggestion in closing this letter, and that is in advising your readers to add to the exceedingly good list of "E. M." the following Roses:—Teas: Madame Cusin, Cleopatra, and Madame de Watteville, and to H.P.'s Margaret Dickson, Comte Raimbaud, and Horace Vernet.—CHARLES T. GRAHAM.

P.S.—I have carefully gone over the figures, and eliminating all cases where less than four were shown in any class, I find that if four prizes had been given at the N.R.S. C.P. meeting the figures would have been increased by 710, and not "about 1000," as I said at a guess, but this would bring Mr. Mawley's figures up to 2385, by far the highest ever shown, and proving what a success the Show was.—C. T. GRAHAM.

HYBRID PERPETUALS IN POTS.

It is impossible to have these in the most satisfactory state if the plants are potted late in the season and then forced the following spring. They should be lifted and potted while their foliage is perfectly fresh. If the plants are obtained from a distance strict injunctions should be given so that the roots are not dried either before or during transit. This is important. Directly they arrive soft ends or long shoots may be reduced and the plants placed at once into clean well drained 7-inch pots. The compost may consist of good fibry loam, not too light nor too heavy. If the latter, coarse sand should be added; if the former, clay may be dried, reduced to a powder, and incorporated with the loam. One-seventh of decayed manure may be added, one 6-inch potful of soot, and the same quantity of bonemeal to each barrowful of loam. The compost must neither be too wet nor too dry, and should be pressed firmly into the pots.

The plants should not be stood outside, where the soil is exposed to the drying influences of the weather, necessitating frequent waterings. They do not succeed under this system. The pots should be plunged at once in ashes, covering the surface, and then no water will be needed. The only attention required is to syringe them during dry weather, to keep the foliage fresh. This will induce the formation of roots, which will extend rapidly. Soil that can be kept moderately moist is in the best possible condition to favour root development. Before it is necessary to place the plants in frames for the winter they will have made abundance of roots. The growths can be partially shortened back for convenience. It is a good plan to plunge the pots in the frames for the winter; during this period they should enjoy abundance of air when the weather is favourable.

If frames can be devoted to these plants in spring, pruning may be done in February, the growths being well cut back. Pruning should be left until the end of March if the plants are plunged outside. The former is the best method to prepare the plants for forcing. This is not all, for if the blooms are really required, under cold frame treatment they will come into flower before outside plants. The growth will also be made and ripened earlier, which is an advantage where they are required for forcing early in the following season.

Where Roses are kept in pots year after year for forcing they ought to be shifted periodically until they are established in 10-inch pots, and afterwards the soil should be partially reduced annually during the months of July or August, while they are outside.—B. O. M.

INTERNATIONAL HORTICULTURAL EXHIBITION.

IN our last issue we made a brief reference to the awards given to season exhibitors at the International Horticultural Exhibition. Some of the exhibits, however, are worthy of more than a passing notice, and therefore further allusion to a few of the most noteworthy may be made with advantage. It might also be mentioned that the Exhibition closes on Saturday, October 15th, and those who have not visited it yet should do so at the earliest opportunity. The names of some of the principal season exhibitors are embodied in the following notes.

GLASS STRUCTURES AND HEATING APPARATUS.

These are well represented. Among the numerous glass structures that have been on view for some months past, the splendid exhibit sent by Messrs. W. Richardson & Co., of Darlington, stands out conspicuously. A gold medal has been awarded this contribution, which includes a well-built conservatory and garden frames of various forms. The three-quarter span-roofed frames are useful structures for growing plants, and should be extensively used in all gardens. For amateurs the "Cottage" plant frame is a handy little structure, deserving of more than a passing notice. Near by, and of no less importance, are the structures erected and shown by Messrs. Crompton & Fawkes of Chelmsford, for which a silver medal has been adjudged. This firm also shows an elaborately built conservatory, the roof bars of which are made with their improved drip grooves. Frames of various kinds, useful and handy, are likewise exhibited by Messrs. Crompton & Fawkes. Messrs. Mackenzie & Moncur, Edinburgh, were awarded a silver-gilt medal for a specimen conservatory; and Messrs. C. Toope & Son, Stepney Square, E., show a model greenhouse, fitted with Toope's patent fog annihilator. Other firms also exhibit glass structures, including greenhouses, conservatories, vineries, and frames.

Of heating appliances these are numerous, and of every conceivable size and shape. The Thames Bank Iron Company, Upper Ground Street, Blackfriars, secure a gold medal for a magnificent display of boilers. The welded improved Trentham, new patent horizontal tubular, and the champion horizontal are powerful boilers, capable of heating an

immense structure or long ranges. The last named boiler is specially designed to meet the requirements of large growers, and by a simple arrangement of the flue plates nearly the whole surface of the boiler is exposed to the fire, thus increasing the heating power. Smaller apparatus suitable for amateurs' greenhouses, also for heating rooms, halls, and churches, are also shown by this firm, as likewise are a large number of hot-water pipes and various fittings. The patent reliance rotary valve, which is simple in construction, and not liable to get out of order, is conspicuous among the numerous other fittings. Messrs. Crompton & Fawkes show Fawkes' slow combustion apparatus, which is a tenant's fixture, and can be easily erected, while Messrs. Richardson and Co. secure a silver medal for heating appliances, which include Richardson's patent hooded tubular boiler in various sizes.

LAWN MOWERS AND WATER APPLIANCES.

Turning to lawn mowers one cannot fail to notice the magnificent stand exhibited by Messrs. Ransomes, Sims & Jefferies, Limited, of the Orwell Works, Ipswich. Here we have machines of all sizes and elegant appearance, fitted with all the latest improvements, including Ransome's patent single screw adjustment of the cutting cylinder. This the firm claims to be the best and most simple form of cylinder adjustment ever invented, for which a certificate has been awarded. Horse and pony machines are included in this stand, as also are hand machines in many sizes. The Anglo-Paris is one of the latest introductions of the firm, and this is a beautifully finished, easy working little machine. A gold medal has been awarded Messrs. Ransomes, Sims & Jefferies for their splendid contribution. In close proximity to the last mentioned stand Messrs. A. Shanks & Son of Arbroath and London make a good display of lawn mowers, gaining a silver medal. This stand also includes lawn mowers of all sizes, from 10 inches in width to the splendid 48-inch horse machine. These are likewise simple in construction and of excellent appearance, embodying all the modern improvements, which enable them to perform the work in a most efficient manner. The new light lawn mower is one of the firm's latest introductions, and this can be had in various sizes from 10 to 14 inches in width. This is a light machine and can be used for all kinds of work.

Regarding the display of garden hoses, pumps, and water appliances, that of Messrs. Merryweather & Co., Greenwich, has attracted some considerable attention, and for which a gold medal has been awarded. Here are hoses of the best make, and suitable for gardens of all sizes. The garden engines and syringes also make a good display, the former being handy and of elegant appearance. The Sphincter Grip Armour Hose Co., 9, Moorfields, London, E.C., also showed innumerable coils of garden hose in various sizes, syringes, pumps, and spray distributors. A bronze medal has been awarded this firm; and a silver medal goes to Messrs. Joseph Davis & Company, London, for rain and snow gauge, and certificates for thermometers and barometers. Messrs. J. H. Heathman and Company, Endell Street, W.C., have secured a silver medal for hoses, syringes, and their noted telescopic extension ladders. The latter are invaluable in the garden and for using in lofty conservatories and other structures, as well as for home use. These are now, we believe, being used in the Royal Gardens at Frogmore. Messrs. Shand, Mason & Co., London, also made a display of garden hoses and pumps, for which a silver medal has been awarded.

MANURES AND INSECTICIDES.

These are also extensively and well shown. Messrs. Corry & Co., London, secured a bronze medal for an effective stand of artificial manures, insecticides, and various sundries. A similar award goes to Mr. J. Bentley, Barrow-on-Humber, for weed destroyers and insecticides, and a certificate of merit for a paraffin oil insecticide. Messrs. Clibran and Sons, Altrincham, have been awarded a bronze medal for a stand of insecticides, amongst which the Eucharis mite killer and Campbell's fumigating insecticide figure conspicuously. Certificates also go to Messrs. W. Richardson & Co., G. Shearod & Co., J. Pinches & Co., and B. S. Williams & Son for exhibits in this department. Messrs. W. Wood & Sons, Wood Green, N., show an enormous quantity of insecticides, manures, peat, and other garden sundries, securing a bronze medal thereby and several certificates. The "Stott" Fertiliser and Insecticide Distribution Company also gain certificates for their specialities, and the same applies to the Horticultural Supply Company, London, who show various sundries. Mr. W. Colchester, Ipswich, likewise shows samples of Ichthemic guano and other manures, for which a certificate has been awarded.

POTTERY AND MISCELLANEOUS.

Messrs. R. Sankey & Co. have staged a characteristic display of garden pottery, and gain a silver medal. Fancy pots of various makes for hanging on walls are included in this exhibit, as also are Orchid pans, pots, and baskets. Messrs. W. S. Iles & Co., Camberwell, S.E., also show a large quantity of garden pottery, from the most miniature to the largest size. Rustic pots and pans are a feature here, these being effective, and useful for the culture of Ferns or Orchids. A gold medal goes to Messrs. F. Rosher & Co., Upper Ground Street, E.C., for a splendid display of beautiful statuary and balustrading. The Australian Irrigation Colonies, London, gain a silver medal, a design for the general improvement of grounds, and show boxes of Apricots and raisins, the first importation of such fruits from Australia. Messrs. Ph. Mayfarth and Co., 16, Mincing Lane, E.C., and Frankfort, have gained a silver medal for methods of irrigation, and they also make, as already reported in these pages, a speciality of fruit evaporators. Messrs. B. S. Williams and Son, Upper Holloway, have been awarded a gold medal for

sundries. Messrs. Reid & Bornemann, Sydenham, gain a silver medal for a design for laying out a typical estate of 100 acres; and Messrs. L. Farina & Co., London, and Madame Gofton, Norwood, similar awards for bouquet papers and miscellaneous decorative requisites.

It may be mentioned that the judges at the Fruit and Potato Show last week reconsidered their decision, and awarded Messrs. E. D. Shuttleworth & Co., Peckham Rye, a gold medal for a group of Palms instead of a silver-gilt one, as reported last week.

THE UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

THE sixth anniversary dinner of the United Horticultural Benefit and Provident Society was held at the Cannon Street Hotel, London, E.C., on Wednesday, October 5th. Mr. J. Fraser of Lea Bridge occupied the chair, and he was supported by a large number of well-known horticulturists. Amongst others present we noticed the Rev. W. Wilks, Messrs. H. J. Veitch, N. Sherwood, — Fisher (Fisher, Son & Sibray), J. Cheal, N. Cole, G. Ingram (Gardeners' Royal Benevolent Institution), W. Marshall, J. Laing, J. Hudson, H. Cutbush, D. Dewar, C. W. Cummins, H. Herbst, and W. Collins (Secretary).

After the customary loyal toasts the Chairman proposed "The United Horticultural Benefit and Provident Society." In doing so he gave a review of the institution, remarking that twenty-seven years ago himself, Mr. W. Marshall, and another friend met at the Green Dragon hostelry in Bishopgate Street, to promote the Society. In the early days of its existence, however, it was attended with great difficulties. He was treasurer at the time, and the bank in which the money was invested failed. Thanks, however, to the efforts of a hard-working Committee, the Society gradually rose from obscurity, and was at the present time one of the most flourishing institutions in the country. Ten or twelve years ago they had less than £1000, but now he was proud to announce that between upwards of £7000 and £8000 were invested. Mr. Fraser made a strong appeal on behalf of the Society. He eulogised the Gardeners' Orphan Fund, remarking that by subscribing to it gardeners were laying by a provision for their children, but in doing so they must not forget to provide for themselves. Sickness, he said, came, and would come upon all, and it was most important that gardeners should make provision for themselves in that respect. Mr. G. Baker in responding, said it was necessary for gardeners to have a benefit society. He was one of the original promoters, and the Society was founded for the benefit of young men. He hoped that all head gardeners would point out to young men employed under them the advantages of this institution, and induce them to become members. Mr. Hudson, who also responded, likewise pointed out the advantages gained by becoming members of such a benefit Society.

Mr. Nathan Cole gave "The Life and Honorary Members," coupling with it the name of N. Sherwood, Esq., a "life member," and the founder of the convalescent fund, a recent important addition to the institution. Mr. Sherwood responded, and on rising was received with much enthusiasm. It had always, he said, given him the greatest pleasure to be present at the annual dinner, and he considered it a duty to offer his small mite. The great institution—for such the United Horticultural Benefit and Provident Society was—was teaching gardeners the noble virtue of thrift. It was a gardener's duty to put by for a rainy day. As regards the convalescent fund, he thought every gardener might with advantage bring the matter before his employer. Gardeners required convalescence as much as, and perhaps more, than anyone else, and if the employers had the subject pointed out to them he had no doubt they would willingly give their assistance. It had occurred to him that a few friends present might assist, and on making an appeal to them they had liberally responded. The result, he was glad to announce, was that nearly £30 had been subscribed in a few moments.

The Chairman proposed "Kindred Societies," with which the names of Mr. W. Marshall and Mr. G. Ingram were coupled. The first named gentleman, representing the Gardeners' Orphan Fund, said there need not be any clashing between the kindred societies, inasmuch as each had its own office to fill. Mr. Ingram acknowledged the usefulness of the United Horticultural Benefit and Provident Society, and made an appeal for the Gardeners' Royal Benevolent Institution.

"The Treasurer" was the next toast given by the Chairman. At this point the most pleasing incident of the evening occurred—namely, the presentation of a handsome gold watch, accompanied by an illuminated testimonial, to Mr. J. Hudson, the Treasurer. In making the presentation, Mr. Fraser said that, to a great extent, the success of the Society was due to the exceptional abilities of Mr. Hudson. The latter gentleman, who was enthusiastically cheered, in replying, said he could not express his gratitude for the honour the members of the Society had paid him in making the presentation. He had only done his duty. All the officers of the Society had worked hard; they could not afford to have drones in the hive. He had always taken a pleasure in inducing gentlemen to become honorary members, and he hoped to be spared for many years to help forward the Society.

Mr. H. J. Veitch gave "The Officers of the Society," and said all young gardeners should take an example from Mr. Hudson, whom he had known for many years. Messrs. J. Wheeler, N. Cole, and W. Collins, whose names were coupled with the toast, responded in suitable terms.

Mr. W. Marshall proposed "The Chairman," to which Mr. J. Fraser briefly responded, remarking that he was thoroughly convinced of the usefulness of the Society. Mr. J. Cheal gave "The Visitors," and Mr.

Fisher responded. Mr. H. Cutbush, Highgate, proposed "The Press," to which Mr. B. Wynne made a brief response.

The tables were tastefully decorated by Mr. J. Chard in his characteristic manner, and an excellent musical entertainment having been provided, a most enjoyable evening was spent.

AGAPETES BUXIFOLIA.

WHEN seen at its best *Agapetes buxifolia* (fig. 46) is a beautiful plant, and it is surprising that it is not more generally known. It is a relative of *Vacciniums*, and under good management will produce immense quantities of rich scarlet tubular flowers, which are very attractive. Its culture is not difficult, though, like the *Erica* family, it requires careful attention. A compost of good peat, a little turfy loam, and sand suits it admirably if the pots are thoroughly drained. Watering must be carefully performed, never allowing the soil to become too

FIG. 46.—AGAPETES BUXIFOLIA.

dry, or, on the other hand, excessively saturated, either being fatal to the plant. Having a tendency to grow somewhat straggling, a little pruning is sometimes necessary to keep the plant in shape.

GRAPE VINES AND THEIR CULTIVATION.

[An essay read at a meeting of the Devon and Exeter Gardeners' Association on the 5th of October, 1892, by Mr. McCORMICK.]

THE Vine is a remarkably free growing plant, and is found in a state of great luxuriance under many opposite conditions, and in soils of a widely different character. The soil which I consider best suited for it is a fibry yellow loam, neither too light and sandy nor too heavy and adhesive. Vines never succeed in wet, clayey, tenacious soil, a certain amount of aëration and porosity appearing to be an absolute necessity, with abundance of water at certain seasons. The turf should be cut from an open pasture, not from a wood or near the roots of trees, lest pieces of wood or of roots remain to decay and cause fungus. It should also be cut while it is dry. Many soils are quite spoiled by being handled whilst in a wet condition. Some cultivators make the borders in layers, first a layer of turf, then so much lime rubbish, or whatever is being added to the soil. Whether this is the right or the wrong practice I will not attempt to say. I advise chopping the turf

with the grass and fibre roughly to pieces, and to 5 or 6 cubic yards of this add 1 yard of old lime rubbish or broken bricks, a portion of charcoal, wood ashes or burnt soil; these well mixed will constitute the main body of the border, but are subject to considerable modification as to proportions according to the quality of the loam. If this be of a sandy nature less of the lime rubbish must be used, as the object in employing it is to give porosity to the soil. If, on the other hand, it is of a clayey nature a greater portion of lime rubbish will be required.

In many places it may be very difficult to obtain soil at all approaching that which I have recommended, but let no one despair of growing Grapes on that account. Vines will grow well in soils of a much inferior nature under careful management. I recommend that which I have found to be the best, and I always try to get it as near as possible. If inferior soil is used in the formation of the border extra top-dressing will make up for the deficiencies, but I have always found the best results in every respect when the other ingredients mentioned are added in their proper proportions for the production of Grapes and the general constitution of the Vine.

MANURES.

For the growth of the Vine nearly all soils require the addition of some fertilising agent. Not very many years ago it was a popular plan to bury the carcasses of animals such as horses, cows, &c., in the borders, under the mistaken impression that the roots revelled in such putrid matter. A more erroneous idea never existed. At the present time very different notions prevail in regard to manures, and also the making of Vine borders. Some of the best cultivators now have their soils analysed with great care, and different ingredients in which they may be found deficient added with mathematical precision. In the formation of a Vine border which is intended to be of a permanent nature the manures that may be used should be of a lasting character, so that it will afford support to the Vine as long as possible. The generality of gardeners have now realised that to mix quantities of farmyard manure with soil for a Vine border is a mistake, for such manure does not contain more than 3 per cent. of the food the Vine requires, the balance being made up of inert matter, which clogs the pores of the soil, excludes the air, and leads to the border becoming sour. This evil is, I think, entirely obviated by the use of Thomson's manure, which I am perfectly satisfied contains everything the Vine requires, and so blended that while a necessary section of them comes into action at once others remain as a reserve for later use. Thus while the plant is at once stimulated and nourished there is ample provision made for its permanent support.

Messrs. Thomson & Sons' Vines at Clovenfords, Galashiels, were planted about twenty-two years ago in such soils as they could procure. It was largely composed of the *debris* of the Silurian rocks of the district, for it was chiefly procured by the roadside, and the roads are made up of the Silurian stone known to be cold and poor. After they had been planted from eight to ten years they began to deteriorate rapidly, as Vines often do at their age in good soil. Some hundreds of tons of manure procured from the cow feeders was applied, and the result was better foliage towards autumn, but the bunches shrank worse than ever. The use of the manure was then abandoned, as also bones, and now their own stimulant is employed exclusively. It would be a waste of time for me to attempt to give an adequate idea of the immense crops of Grapes cut from these Vines annually. I believe that Vine borders made up of fresh turf and Thomson's Vine manure in the proportion of half hundredweight of manure to one ton of loam will prove satisfactory, and will maintain the Vines in health and fruitfulness for at least a quarter of a century. If after the second or third year 2 lbs. weight per square yard of the manure are forked into the surface of the border every spring, and 1 lb. per square yard is added after the Grapes are thinned, the roots will be kept near the surface and be fed there. Bones, which are so much recommended, are of slow action unless they are finely ground. I have seen them in borders which had been made up for thirty years little reduced and not a root near them.

BORDERS.

Vines may be grown in a small space and in very little soil, as is evident by the splendid results obtained by their cultivation in pots, but they are soon worn out; one crop one season and they are done. If Vines are desired that will last for twenty-five or thirty years borders of considerable size must be provided, and this is best done in sections. If young Vines are to be planted 4 to 6 feet will be found sufficient to make up the first season, adding a similar portion as the roots extend, and so on until the space is filled up.

Much discussion has taken place as to having the Vines planted with the roots inside or in borders outside the house. I prefer the former for very early forcing, as also for late houses. The disadvantages are the great amount of labour required in watering, and the skill and care necessary in keeping up the requisite degree of moisture at the roots. A scarcity of water, or a little neglect in its application, will ruin the crop. On the other hand, outside borders require little attention in regard to watering, except in a summer like that which we have had. For the general crop of Grapes, and for all ordinary cultivation where constant care cannot be given, outside borders are preferable.

DRAINAGE.

This is one of the most important matters in the formation of a Vine border, and one that in some situations entails a considerable amount of trouble and expense to render it efficient. It is a point that should always be taken into consideration in selecting a position for a vinery,

for if it cannot be drained freely it is not a proper site. Many gardens with a gravelly subsoil are well drained naturally, and so require little preparation, but I would never trust to that. It is better to take all ordinary precautions at the first rather than run any risk, and then after several years of loss and disappointment to have all the work to do over again. A considerable amount of draining material should be placed over the whole of the bed of the border—say, from 1 foot to 15 inches in depth, and certainly never less than 9 inches; the back of the border ought to have a few inches more than the front, sloping into a drain 10 or 12 inches lower to carry off the superfluous water. The best material for drainage will be found in old bricks and lime rubbish. In the formation of a Vine border everything ought to be taken into consideration, not only the position, but also the level of the border. The amount of excavation necessary in making up the border will be determined by its depth, measuring from the surface level; thus a border raised 2½ feet requires only to be excavated to a depth sufficient to hold the drainage. It is folly to dig a deep pit, which only acts as a reservoir for the drainage of the surrounding land, and nothing could be more injurious to the roots of Vines.

COVERING BORDERS.

It is an old custom, and I think considered by many to be needful, that Vine borders should be covered, but I do not now think it is necessary in ordinary cases. The beneficial effects of frost on soil are well known, and it is a good practice to expose the soil of a Vine border to its action as much as possible. For early forcing a good covering of dry leaves will ward off cold rains, and, no doubt, assist in keeping up the temperature of the border, which is a most important feature in an early vinery; but for late and general purposes the border is better exposed to the free action of the weather. I remember very distinctly a case which came under my notice, and which I took particular note of at the time. While working as a journeyman gardener in a rather remote corner of Scotland where we had a fair share of frost and snow, a span-roof house of 70 feet was pruned and thoroughly cleaned the first week in January; the pipes were emptied of water, and the ventilators opened up until the 1st of March. On four mornings in January 20° of frost was registered. There was no mulching on the border either outside or in, yet I never saw Vines start better than these did.

WATERING.

More Vines are ruined through the want of water than perhaps any other cause known. The quantity of water a Vine requires when growing in well-drained borders is astonishing. I do not think they can receive an excessive supply. Before the Vines are started into growth every particle of the soil should be thoroughly saturated, and from the time they come into leaf until they begin to ripen the fruit. After that a somewhat drier condition should be maintained, but the soil should not be allowed to become dry even then. I never apply artificial manure while the border is in a dry state. I think it has much more effect when applied two days or so after rain, and then I give just sufficient water to carry the manure to the roots.

RENOVATING OLD BORDERS.

Old and apparently worn out Vines are sometimes restored to vigour by a little fresh material being applied to the roots. It is the fear of loss, however little it may be, that often prevents any adequate means being taken to improve them; but by careful management Vine borders may be renewed without any loss. If these facts were fully recognised we might see less poor Grapes. One difficulty in the way of this is to have the fruit the Vines may be producing ripe in time for the operation to be performed sufficiently early to get the roots to take to the new soil before the end of the season. As soon as the fruit is cut, say about the end of July, clear away the old soil and trace out carefully all the roots that may be found. These must be shaded from the sun and frequently watered; then make up the border with fresh soil and replant as soon as possible. Success greatly depends upon the time taken in doing this, as the Vine roots suffer greatly if kept long out of the soil, but if care be taken a few days will do no harm. Notch the larger roots here and there with a knife, as it induces them to throw out plenty of young roots where cut. In making up the border make several layers of roots, place a few in the first layer of new soil, then sprinkle on a few inches more, then lay in a few more roots, and so on, having the last layer of roots not more than 3 inches from the surface. The Vines will flag for a time, but shade them heavily for a time, then slightly for a little longer, water them well, and there need be no fear of the result. I have just finished the renewal of one of the borders at Ware House. It is much later in the season than I like for the work. At first it was my intention to partly renew the border, but finding the drainage in a very unsatisfactory state I turned the whole of it out. The new border is composed of the same ingredients as I have recommended for the formation of borders, 1 cwt. of hoof and horn shavings being added in addition to the manure. I consider it a fine fertiliser to put into the first layers of soil.

In regard to the houses for the cultivation of Grapes the greatest latitude may be allowed. It is not to be assumed, however, that certain structures are not better adapted for their cultivation than others. It is the little difference from this or that which leads on to failure or success as the case may be. A house which may be very suitable for early Grapes may be unsuitable for late Grapes, and *vice versa*. Vineries are of three classes:—1, The early vinery for early or forced Grapes. 2, General crop, including all unheated houses.

3, Late vineries for keeping Grapes late in the season. Special arrangements are required in each case, but I cannot attempt to describe them here; I will leave the details to be fitted to each particular case.

(To be continued.)

NATIONAL CHRYSANTHEMUM SOCIETY.

OCTOBER 12TH, 13TH, AND 14TH.

A FAIR display of bloom is gathered together at the Royal Aquarium this week, the occasion being the early show of the National Chrysanthemum Society. The Japanese are the main feature, most of the other sections being only poorly represented, but on the whole the Exhibition is worthy of a visit.

Two groups are in competition in class 1, the better being that arranged by Messrs. Reid & Bornemann, Sydenham, who display their usual combination of healthy plants, good blooms, and tasteful disposal. The main position is composed of Japanese and incurved, such as Avalanche, W. Tricker, Beau Rêve, Mons. Bahuant, Sunflower, W. H. Lincoln, Mr. Chas. Shea, Geo. Jones, and Madame Harman Payne. Towards the front are a number of free-flowering Pompons and reflexed Japanese, such as Comtesse de Cariel, Madame A. Colimiche, and Piercy's Seedling, which give a good finish to the group. Mr. Davis is second. The first prize for six plants goes to Mr. Nedry, gardener to the Rev. R. W. Powell, Holy Innocents, Hornsey, who has Mrs. Burrell, Madame Desgranges, and J. G. Wermig loaded with flowers, the first especially. There is no other competitor. He also wins with twelve, profusely bloomed examples of Madame Desgranges, Mrs. Burrell, Mrs. Hawkins, and George Wermig representing him. Mr. Howe, gardener to H. Tate, Esq., Park Hill, Streatham Common, is second.

The principal class for cut blooms is that for the Japanese, in which the first prize goes to Mr. W. Higgs, gardener to J. R. Hankey, Esq., Felcham Park, Leatherhead, who has good blooms of W. H. Lincoln, Violet Rose, Gloire du Rocher, Louis Boehmer, Mons. Bernard, Excelsior, and Mrs. Nisbet. They are heavy flowers, well filling the stand. Excelsior is a fine telling flower of a rich rose colour, and with very broad florets. Mr. Cox, gardener to J. Trotter, Esq., Bickenden Grange, Hertford, is second with a heavy stand of fresh flowers, amongst which Avalanche, Boule d'Or, M. Tarin, Mrs. F. A. Spaulding, Miss Anna Hartzhorn, and Mdle. Marie Hoste are conspicuous. Miss Anna Hartzhorn, an incurved Japanese, is the greatest ornament of the stand. The florets are broad and of a beautiful wax-like texture, somewhat reminding one of Puritan. Mr. Ritchings, gardener to Dr. Frankland, The Yews, Reigate, is third. He has grand flowers of Edwin Molyneux, Avalanche, but many of the others are somewhat small. In the class for twelve Mr. Rowbottom, gardener to H. R. Williams, Esq., The Priory, Hornsey, wins with a very fine box considering the early date, for if the flowers are not of the largest size they are very fresh and of beautiful colour. W. H. Lincoln, Edwin Molyneux, Coronet, and W. Tricker. Mr. James Agate, East Street, Havant, is second with a stand mainly composed of light flowers; and Mr. Cox third.

Incurved are not so abundant, there being but one stand of twelve, and it is evident we must look to the other sections for early shows. Mr. Wells, Earlswood Nurseries, Redhill, was the solitary exhibitor, and he is placed first for a moderate collection, composed of Mons. Bahuant, Prince of Wales, Mrs. Dixon, Bonsignour (?), Jeanne d'Arc, Madame Mistral, and Mr. G. Glenny. He is also first for six, but in both cases the varieties are a mere shadow of their average quality, and the classes serve no useful purpose. Mr. Davis wins with twelve bunches of Pompons, and Mr. Tickner, gardener to J. Watney, Esq., Thermanbury House, Reigate, with six. The latter has a good stand, the varieties being Black Douglas, Mdle. Elise Dordan (very neat), J. Maurisol, Souvenir de Jersey, La Vogue, and Curiosity.

In the single-handed gardeners' class for twelve Japanese, Mr. Tickner is the only exhibitor, and is placed first for blooms of medium quality, W. H. Lincoln being perhaps the best. He also wins with six, which are of a very similar character to the twelve. Mr. Tuck, gardener to J. Boney, Esq., Cholmeley Lodge, Highgate, is second. A second prize for twelve bunches of Pompons goes to Miss Debenham, St. Peter's, St. Alban's.

Messrs. W. & G. Drover, Fareham, exhibit a new board for Japanese which they propose for general adoption. It is 28 inches by 21, the holes 7 inches apart, the height at the back 8 inches, and at the front 3 inches. Mr. W. J. Godfrey, Dartmouth, exhibits two new Japanese seedlings, one named Beauty of Exmouth being a very promising white variety. It has long, slender, curled florets, is of good size, and very deep. At present the blooms are unfinished, but it should develop into a champion flower. The other, Duchess of Devonshire, is, we understand, a seedling from Stanstead Surprise, and is not yet in a condition to be judged. Mr. Owen, Maidenhead, has a number of English seedlings, General Hawkes and Lady Brookes, honoured by the R.H.S., being among them. October Yellow is a promising decorative variety, and Mrs. C. Myers a pleasing white Japanese. Percy Waterer, Esq., exhibits a neat box of Lady Selborne, which receives honourable mention. Dr. Walker exhibits his cup and tube. Messrs. Pitcher & Manda, Hextable, Swanley, have a collection of cut blooms and also herbaceous flowers (silver medal), and Mr. Davis receives a similar award for a mixed collection. Mr. H. J. Jones, Lewisham, has a display of Chrysanthemum blooms, interspersed with Ferns, and a silver medal is awarded. Messrs. Laing & Sons have a large and beautiful group of Begonias, and also a very extensive and fine collection of fruit and Potatoes (silver-gilt medal). Messrs. Cannell & Sons exhibit a number of beautiful Cactus

Dahlias. Mr. W. Wells has an excellent mixed collection of Chrysanthemums (silver medal). Messrs. Cheal & Sons, Crawley, have a long table of splendid fruit (silver-gilt medal), and Mr. M. V. Seale, Sevenoaks, a fine collection of Dahlias (silver-gilt medal).

There is some grand produce in the competition for Messrs. Sutton and Sons' special prizes, but time does not permit of particulars being given. In the evening of the first day a Conference was held on the subject of boards for Japanese, a report of which will be given in our next issue.

HARDY FRUIT GARDEN.

The Fruit Room.—Every season the fruit room ought to have a thorough overhauling and a good cleansing given. The walls ought to be whitewashed and all the woodwork scrubbed down, the aim being to make the room as sweet as possible. Apples, and in a lesser degree Pears also, are very porous, and the flavour is easily tainted in a musty atmosphere or from contact with anything scented in any way. Nothing in the shape of hay or straw should be permitted in the fruit room, and the fruit ought either to be stored on the clean boards or on fresh "kitchen" paper.

Root-pruning.—When fruit trees grown on the various restrictive systems assume year after year a chronic state of unfruitfulness there is something wrong either with the roots or the methods of managing the branches. Making too much wood in summer, before any attempt is made by the cultivator to restrain the natural vigour within proper bounds, is usually the cause of destroying the necessary balance between root and branch. Summer pruning does much to restrain the growth of wood and concentrate the sap in the fruit-bearing spurs, as well as in the formation of buds that will eventually be fruiting spurs. But sometimes, owing to the excessive vigour of strong roots, correct pruning and branch management are not sufficiently capable of sustaining trees in a permanent bearing condition. Root-pruning then becomes absolutely necessary. The production of a large amount of gross wood and correspondingly ample area of leafage has a powerful effect on the roots, which, as a rule, when receiving extraordinary stimulus, descend perpendicularly. In doing so, especially in rich ground, they become very strong. The same result also occurs in a moist subsoil. The results then are coarse, thick roots followed naturally in the growing season by gross watery wood.

Benefits of Root-pruning.—The immediate effects of severing strong, coarse, and powerful roots is to check the vigorous flow of sap in the branches; this will induce a steadier distribution through every part of a tree. Hence many buds, some of them weak fruit buds perhaps, which have hitherto been passed by, will secure a chance of obtaining that necessary support which they need to become fruitful. The check upon the system of the trees is also apparent in the formation of fresh roots, which, carefully encouraged, will be, and continue to be, of a fibrous character. They are always produced nearer the surface than those of a coarser nature, and are capable of absorbing food in a manner that does not exceed the requirements of the trees. Roots of this kind are termed feeding fibres, being generally abundant in proportion as the trees are fruitful. When duly supplied with roots like these ramifying near the surface in a suitable medium most trees continue fertile. They require, however, to be encouraged and sustained by adequate supplies of food placed within their reach, which is usually accomplished by top-dressings of soil and manure, with due supplies of moisture.

Time to Root-prune.—Severe cutting or shortening of the roots should never be done whilst trees are in full leaf, nor yet carried to excess at any time. The larger the trees the more care must be exercised in the operation. The latter part of October and during the first half of November are undoubtedly the best times for root-pruning, because then the soil has still some amount of warmth in it. The pruned roots can take advantage of this to commence first their work of healing, then of fibre formation before the sap is quiescent or at its lowest ebb. All the most valuable trees that require careful manipulation should be operated upon at the earliest opportunity, while those of less moment may be deferred to the later period, or even to any suitable time during the winter; also early spring, before growth commences, is a suitable time. Autumn, however, is the best time when it can be done, roots then forming more quickly.

Method of Root-pruning.—It is not advisable to sever the roots completely round of any very large specimens, but only to treat one-half or one-third, according to the age and strength of the tree. Take also into account the number and vigour of the strongest and largest roots. Sufficient check will be given at one time by this method without endangering future growth. The following season a part or whole of the remaining roots can be operated on as may appear necessary, taking as a guide and criterion for forming a proper judgment on the matter the character of the season's growth. Should little or no diminished grossness be apparent, it is evident that further reduction of roots must be made.

Details of the Operation.—These are simple, but upon their careful carrying out greatly depends the success or otherwise of the experiment. First of all a wide trench should be cut out at a distance of from 3 to 6 feet from the bole or stem. The exact distance must be regulated by the size of the tree. All roots found on the side of the trench should be cut off. When sufficient soil has been taken out to form a deep and wide trench the bulk of soil and roots surrounding the stem must be carefully examined as the operator, standing in the trench, works away the soil from among the roots with a fork. The strong roots, perhaps roughly severed when cutting the trench, must be traced to see whether they have branch roots of a similar strength. In many cases the chief cause of vigour and over-luxuriance lays in the perpendicular descent of the tap root, which requires to be severed. Some trees, when the principal roots on one side have been cut, can be carefully drawn over so far as to expose to view the whereabouts of this main feeder. All cuts should be made on the under side of roots, drawing the knife from the tree towards the operator. Others, such as those growing against walls and any not desirable to disturb too much, can be undermined to reach the tap root.

General Treatment of the Roots.—During the operation some amount of care is necessary in preserving those retained from injury and preventing shrivelling by too long exposure to the effects of sun or drying winds. As a number are loosened from the soil it is best to fasten them together out of the way, and cover with some damp material such as hay or a moistened mat. It will be found, as a rule, that the roots of luxuriant trees have had a downward tendency. This must be rectified by encouraging a more horizontal growth, which can be done in the process of re-laying the smallest roots, placing them so that when fibres are emitted they will extend near the surface. In trimming the roots special care must be taken that every jagged end or injured portion is cut clean to good parts. The proper way is to cut the roots from the bottom upwards at the shortest possible angle, using a sharp edged knife. Where any fibrous roots are present those should be carefully retained, and the cuts on the larger roots made as near to them as possible. In filling in the soil introduce some fresh of a light loamy character, but avoid manure mixed with it. Make the soil firm as the work proceeds. Where abundant roots exist they may be shortened at different lengths.

Mulching and Staking.—After the work is completed all trees ought to be carefully secured against rocking to and fro by the wind. The best plan is to wrap some sacking or similar material round the stems at about half way, to which three strong wires should be attached, drawn tight and fastened securely to strong wooden stakes driven well into the ground at an angle beyond the loosened portion; then mulch the ground as far as the roots extend with short littery manure, which will serve to retain some of the warmth in the soil, prevent rapid drying, and resist severe frost.

FRUIT FORCING.

Pines.—*Young Plants.*—These should now be arranged so as to derive the fullest benefit of light and air, keeping the glass clean both inside and outside. As the sun heat diminishes a corresponding diminution of temperature must take place until it reaches the winter standard of 55° to 60° at night, and 65° in the daytime. A high temperature by artificial means only induces a weak attenuated growth in the plants, and that is fatal to their producing good fruit later on. Ventilate freely on all favourable occasions, particularly on fine mornings; but avoid cold drying currents of air, as these only stunt the plants, and cause them to yield fruit prematurely. Make an examination of the plants about once a week for watering, and whenever a plant needs water give it copiously at about the same temperature as the bed, but only when absolutely necessary.

Plants to Fruit Early Next Year.—Queens are the best to afford a supply of early fruit, and to insure the plants throwing up fruit at the proper time they must be given a comparative rest after making good growth. Those intended to show fruit early in the year should be kept in a house with a temperature of 65° in the daytime by artificial means, ventilating at 70° and closing at that temperature, the bottom heat being kept steady at 70° and the night temperature at 60°. Keep the plants on the dry side, watering only when necessary; yet do not let the soil become so dry as to cause limpness of the foliage, which weakens the plants.

Plants Showing Fruit.—Such will afford ripe fruit when it is scarce and dear, therefore give the plants the best position in the fruiting department, both as regards proximity to the light and plenty of space. Keep the bottom heat steady at 85° to 90° at the base of the pots. Maintain a temperature of 70° at night, 5° less when very cold, 75° artificially by day, advancing from sun heat to 85° or 90°, and close the house at 85°. Sprinkle the pathways when their surfaces become dry, and occasionally bedew the plants on fine afternoons. Examine the plants once a week for watering, and when any require it afford a copious supply of clear liquid manure at about the same temperature as the beds; but neither these plants nor fruiters must be over-watered, as that has a tendency to cause the fruit to be black at the centre when cut.

Peaches and Nectarines.—*Earliest House.*—Prune the trees when at rest and put the house in order. The trees having been properly attended to in disbudding, and the growth equalised, there will be little need of pruning. Any weak wood, however, may be removed, and the leading shoots be shortened, so as to originate the requisite growth for furnishing the trellis, and, where too crowded, the

shoots may be thinned. Untie the branches from the trellis, cleanse the house thoroughly, and after washing the trees with soapy water, 3 ozs. softsoap to a gallon of water, dress them with an insecticide before again securing them to the trellis. There should not be any attempt at tight tying, but plenty of space must be left to allow for the swelling of the branches. Limewash the walls, remove the surface soil down to the roots, and supply fresh turfy rather heavy loam, with a tenth of old mortar rubbish and a bushel of wood ashes to each cartload of compost, making firm, and following with a good watering. The outside border also should be surface dressed in a similar manner, and, if in a thoroughly moist state, protect with about 3 inches thickness of leaves and a little litter to prevent their blowing about, as cold rains reduce the temperature of the soil considerably, but allow the soil to be thoroughly moistened before covering. Where the lights have been removed, they may remain off until bad weather sets in, otherwise admit air to the fullest extent.

Second Early House.—The trees now have the foliage down, except a few vigorous ones, and in their case the falling of the leaves may be assisted by lightly brushing them with a broom. Now is the time to cleanse the house and dress the trees, also to top-dress the border, as the insects are then destroyed before they have time to find secure winter quarters, and the roots push into the new soil at once. Where the trees have been properly managed there will be little wood to cut out, confining it to removing any useless parts having escaped the knife at thinning after the fruit were gathered, and these, with other shoots not required for next year's bearing, should now be removed. Any shoots considered too long may be cut back to a wood or triple bud, making sure that the centre one is a wood bud, which is not always the case, and to leave sufficient wood with fruit buds for insuring a crop next year. Shoots of 8 to 12 inches length must not be shortened, nor need those that are very much longer, as all shoots have a few wood buds at the base and one at the extremity, and others amid the fruit buds, especially vigorous growths; but in the case of weak shoots the intermediate buds are generally blossom buds only. To retain much wood is a great mistake, as the trees are weakened by an excess of blossom, and there is not space for training in the necessary growths for future bearing so as to insure their thorough exposure to light and air. If the lights are off, do not replace them until severe weather comes, but allow the borders to become well moistened by the autumn rain. If the lights are fixed allow plenty of air at all times; avoid permitting the borders to become dry, but keep in a moist condition by watering as necessary.

Midseason Houses.—In these the foliage is approaching maturity, and the lights being kept open day and night as they should be, the wood will mature well, and where that is effected the roof lights may be removed, which will ensure an even and thorough moistening of the soil, and there is no water like rain for refreshing the trees and enriching the soil. If the trees are too vigorous, not setting and stoning the fruit well, lifting or root-pruning should be attended to as soon as the wood becomes firm and the buds are plumped, so that fresh roots may be formed, this being more certainly effected when the trees have foliage than when it is deferred until they become leafless. Any trees that are unhealthy should be lifted, and have the roots laid in fresh soil, and this done carefully has a beneficial result.

Late Houses.—Late Peaches are as valuable as they are tempting in appearance, and they ripen under glass in the worst seasons. Barrington and Late Admirable were at no distant date our best late Peaches, and Salwey seldom ripened, and when it did was dry and flavourless. Now we have some first-rate varieties, with size and appearance, and when given due supplies of water and nourishment when the crop is swelling, also when the fruit is taking its last swelling for ripening, the quality is as good as the looks, otherwise the fruit is often dry and mealy. Princess of Wales, Lady Palmerston, Prince of Wales, Lord Palmerston, Sea Eagle, and Nectarine Peach ripen in September as a rule; but we have had fine fruit of those varieties in October, Sea Eagle as late as the 12th of that month. Gladstone, Golden Eagle, and Comet are the latest good Peaches, and the first is unrivalled by any midseason variety for quality. By ventilating freely through the summer they may be had as late as when grown outside, and the fruit can be insured ripening, which is more than can always be effected outside. In cold localities culture under glass is imperative, with command of fire heat to insure the ripening of the wood, the varieties Prince of Wales and Lord Palmerston being unsatisfactory in some districts without artificial heat; but with it they are simply superb in size and first class in quality. The wood should be kept thin so as secure sturdy short-jointed wood and to get it well ripened. Shoots that have borne fruit, and not being extensions, should be cut out as soon as the fruit is gathered. Trees growing too luxuriantly and late may have a trench taken out at such distance from the stem as will check their vigour and cause the buds to become plump, and after remaining open about three weeks the trench should be filled up and the soil made firm.

THE FLOWER GARDEN.

Unightly Flower Beds.—Early frosts sadly disfigured very many flower beds, and a spell of wet sunless weather has spoilt the appearance of still more. Nor is it possible for many of them to recover from these adverse effects, and the sooner the beds are put into a more orderly state the better in most cases. Where the beds have to be filled with shrubs and spring-flowering plants, as much as possible of this ought to be done before November. Dry weather should be chosen for this important work, as then it can be done without unduly disfiguring the walks and turf, and if the beds are a little on the dry side so much

the better, nothing ever thriving so well when it is little better than puddled in. Therefore unhesitatingly break up the disfigured beds, and proceed at once with the work of refilling.

Hints upon Planting.—Nearly any kind or variety of Conifer in a small state looks well in masses, but the coloured forms of *Retinosporas*, *Thujas*, *Cupressuses*, *Yews*, and such like as specially prepared by the leading nurserymen for the flower garden, are by far the most effective. Variegated tree Box, *Hollies* in varieties, *Berberises*, *Ivies*, *Osmanthus*, and *Euonymuses* are also admirably adapted for the decoration of flower beds, and with these may be associated *Pernettyas*, *Cotoneasters*, *Skimmia japonica*, and other berry-bearing plants. Very neat dwarf *Rhododendrons* in beautiful variety and well set with buds can also be had at a comparatively cheap rate, and these are very gorgeous late in the spring. Handsome trees 18 inches to 2 feet in height of the Conifers named are most effective when dotted among dwarf flowering and variegated foliaged plants, and to these may well be added elegant *Yuccas* and variegated *Iris*. All transplant readily both now and again next spring, and if taken good care are available for the beds several autumns in succession. Flowering plants such as *Wallflowers*, *Forget-me-nots*, *Silenes*, *Saponaria*, *Polyanthuses*, *Primroses*, *Daisies*, *Limnathes*, and others should, if provided in sufficient number, be planted rather thickly, as they seldom make much top growth, after being placed in the beds. See that they are in a moist state at the roots before they are lifted, move with a good ball of soil about the roots, and replant firmly. Golden *Pyrethrum*, if not allowed to flower, will be available for replanting, and the smaller Beet from either flower borders or the kitchen garden will give a little colour for several weeks, and if the winter is mild look well till next summer, especially if the flower stems are pinched out. Old *Violas* should have straggling growths cut away, and if divided and replanted will present a very gay appearance next spring, flowering a little later than summer-struck plants.

Spring-flowering Bulbs.—Freely used these enliven the flower garden surprisingly in the spring. *Narcissi*, *Hyacinths*, *Tulips*, *Leucoiums*, *Crocuses*, *Scillas*, and *Snowdrops* associate well with the shrubs and plants already named, or the beds may be principally filled with them and carpeted over with short neat pieces of tree *Ivy*, *Box*, *Aucubas*, *Hollies*, *Laurels*, *Mahonias*, and other evergreens, these presenting a fresh appearance, being a great improvement on the bare soil for several months, and benefit rather than injure the bulbs underneath. Beds of *Hyacinths* in one colour edged with either *Snowdrops*, *Crocuses*, or *Scillas* in contrast are very gay, a change being afforded by a mixture of colours. The same remarks apply to *Tulips* and *Narcissi*, grouping them together answering better than general mixtures. In large beds circular patches of either *Narcissi*, *Hyacinths*, or *Tulips* might alternate with other flowering plants, or dwarf Conifers and shrubs, or they may be interspersed among the latter when these are thinly planted. If *Hyacinths* fill the centre of the bed dispose them 9 inches apart each way, while if the surface of the bed is carpeted with other plants, the bulbs may be put out 12 inches asunder with advantage, the crowns being covered about 4 inches deep. Where the soil is of a heavy nature surround each bulb with sharp sand; *Narcissi* to be treated similarly to *Hyacinths*. Plant the neat growing *Tulips*, notably the *Van Thols*, 4 inches apart and 3 inches deep, but the stronger varieties may be disposed 6 inches asunder. A little fresh gritty soil benefits *Tulips*, and the choicer varieties ought certainly to receive this extra attention. *Snowdrops*, *Scillas*, *Crocuses*, and *Winter Aconite* are most effective near the margins of beds, and planted in double lines or circles. Plant 4 inches deep, and not more than 3 inches apart. On light warm soils *Ranunculuses* may be planted in November, but where the soil is of a cold clayey nature keep them out of the ground till a favourable time arrives for planting in February.

Shrubby Calceolarias.—As yet these plants cannot well be dispensed with in the flower garden, and a good stock ought to be raised. It is not yet too late to insert cuttings. No bottom heat is required, but it is advisable to raise shallow frames well off the ground with the aid of old hotbed material not far advanced in decay, also partly fill the frame with the same and then cover with about 4 inches of light loamy soil, on this placing 2 inches of sifted soil, making this firm and level and facing over with sharp sand. Select short, firm, flowerless shoots, cut these below the third joint, and trim off the lower pair of leaves. Dibble them in at once and just clear of each other, taking care that the cuttings touch the bottom of the holes, fix firmly, and give a gentle watering. Keep the frame close and shaded from bright sunshine till the cuttings freshen up and fail to flag when the sun shines on them, after which ventilate freely in order to keep them as hardy as possible. Protect from severe frosts only.

Bedding Violas.—Autumn-struck plants of these are by far the best for summer bedding, and properly treated they are unrivalled for brilliancy, especially during the early part of the season. Although much hardier (they are quite hardy in fact) *Violas* succeed admirably under precisely the same treatment as *Calceolarias*. Prepare frames as for the latter and select the young shoots springing from the centre of the old plants, make these into short cuttings, dibble them in rather thickly, and treat exactly as advised in the case of *Calceolarias*. Failing plenty of the young central shoots make the best of the flowering tops into cuttings, as these will develop into very good plants, fresh growths springing up from below the surface next spring.

PLANT HOUSES.

Stephanotis floribunda.—Plants that are grown in pots and have completed their growth may be taken from the roof and thoroughly

cleaned. If they are not too large they should be thinly trained round stakes and stood in any dry structure where the temperature ranges about 50°. The plants will need less water during the process of ripening their wood prior to resting. The wood must be thoroughly matured, and a good rest is essential to their flowering profusely another season.

Allamandas.—Where these are desired in bloom as early as possible the plants should be dried at their roots and removed to a temperature of 50° to 55°. They will soon rest under these conditions, and in six or eight weeks may be pruned and introduced into heat. It is not necessary to dry these plants so that every leaf falls from them; on the contrary, all that is necessary is to treat them as semi-evergreen. We frequently prune back the plants when they are in full leaf, provided they have been kept dry and in a lower temperature, and they flower profusely. The *Allamanda* flowers are useful at this season of the year, and may be had by giving the plants brisk heat and supplying them with weak stimulants.

Bougainvillea glabra.—With good and well-ripened growth the plants will be safe in a temperature that does not fall below 45°, and if kept rather dry at the roots the plants will soon go to rest. A lengthened period of rest in a low temperature is essential to the successful flowering of this useful plant. To allow every ray of sun possible to reach the best growths the others may be cut clean away.

Caladiums.—These are rapidly dying down, and should be stored in any dry place where the temperature will range about 55°. We find they rest, and the tubers are perfectly sound in this temperature. If kept in a low temperature the tubers are certain to decay. Some care is needed not to hurry the plants to rest; they should be allowed to die down gradually, and then the pots may be laid on their sides. The same remarks apply to *Gloxinias* and *Achimenes*, but they are safe in a lower temperature.

Justicia flavicom.—Some of the earliest plants are coming into bloom, and may be removed to the conservatory, where they will be found useful. The plant deserves to be much more largely grown for the embellishment of houses that have to be kept gay during the winter and spring. When the first flowers fade place the plants in an intermediate temperature, and they will flower again in due time, in fact for three times in succession, and frequently the second bloom is the best. A temperature of 50° will suit them very well.

Begonias.—Plants raised from seed or cuttings in spring and grown in cold frames will flower profusely during the next two months if placed where they can enjoy a temperature of 50° to 55°. These varieties are invaluable for supplying flowers at this period of the year. However useful such varieties as *Ingrami*, *Knowsleyana*, and others may be at this season the tuberous forms are still more valuable for supplying flowers for cutting for room decoration. Seedling varieties of *semperflorens* may be allowed to come into flower, while those of *semperflorens gigantea* may be pinched to induce them to branch. These thrive well in a temperature of 50°, and may be placed into larger pots if they need it. *Weltoniensis* is nearly over, and the plants may be stood at the back of a vinery to rest; the few remaining flowers can be cut.

Dracenas.—If these plants are checked in their early stages by insufficient root room they seldom do well afterwards. A small shift which will be ample to keep them growing slowly during the winter. Young plants in 3-inch pots must be placed into 5-inch or, they will be useless for growing early in the year. Careful watering is needed after the plants are potted at this season; if overwatered the evil is as bad as if the plants suffered by confinement at their roots.

Gardenias.—Clean these thoroughly, and if the plants have been all grown together divide them into two portions. Place the earliest in a temperature of 5° warmer than the others, and if buds are already formed flowers will soon follow. Do not allow the plants to suffer by the want of water, and be careful not to give stimulants too strong.

Epiphyllums.—Where these were assisted by gentle warmth to make their growth and have been since well ripened in the greenhouse many of the plants will have their flower buds in a prominent condition, and may be placed in a temperature of 50° to 55°. They look well when elevated on pots in a groundwork of *Adiantum cuneatum*. *Epiphyllums* are much more useful during the closing months of the year than when they flower towards spring. Water the plants carefully; the extreme drying system practised by some persons is ruinous.

Dipladenias.—These must be watered with great care, or the plants will be seriously injured. If they have been trained up the roof and the growths are fairly well ripened take them down and train them round stakes. In this way the plants can be more carefully attended to than when their pots are standing behind other plants, practically out of sight.

Ixoras.—As these go out of flower place them at the warmest end of the house, and syringe them freely during bright weather. Watch for thrips, which if allowed to exist will soon destroy the foliage. Apply water carefully, but do not allow the plants to suffer by an insufficient supply.

Gloriosa superba.—Allow this useful plant to go to rest by gradually withholding water. Do not unduly force rest upon it, or the tubers will suffer and feeble growth follow next season.

THE BEE-KEEPER.

APIARIAN NOTES.

FEEDING.

THIS, as I have often explained, is a necessary evil, and should never be resorted to unless it cannot be avoided. There are times when it must be done if profit is the object in view. By feeding, we can start bees to breed at unseasonable times, and sometimes to a greater extent than unfed hives; but the latter in spring, where stores are sufficient, are generally ahead of fed ones when the honey season comes on, with the additional advantage of having a queen less exhausted than are queens of fed hives, the latter often depositing twice or three times the number of eggs that are brought forward. On the other hand, it is sometimes positively ruinous to neglect feeding during May and June. Often in the last-named month bees with plenty of stores, during a spell of wet or cold weather, will eat out every egg and larva, and draw out all young bees. This is a frequent occurrence at the times mentioned, as well as at the Heather. I specially mention this, as I have several inquiries about the conflicting statements of this and Punic bees in other journals. The editor of one of these, in answer to a Scotchman's young bees being cast out, says they "are quite young, unflown ones, and are not likely to have been cast out of the hive by the older bees." Nothing is more sure than they are cast out, and this is carried on to a far greater extent than is often supposed; result the end of all profit.

I could quote hundreds of instances, but the following case that occurred in an apiary near me this summer will illustrate vividly the facts. A favourite and supposed extra strong hive was on the 15th of May quite full of bees, brood, and eggs. On the 22nd of the same month there was not a vestige of brood nor eggs to be seen. To have prevented this extensive "brood drawing," 2 or 3 lbs. of sugar should have been given, and thereafter every day till honey came in, about 2 or 3 ozs. daily, fed in a tin scoop from below. These occasions are the only ones (unless nuclei) when dribbles of sugar should be given. "Stimulative" feeding from a pinhole is delusive. I do not urge bee-keepers to take my word for all that; the least thing they can do is to put both systems to a fair test, and I know, without being told, which will give satisfactory results.

PREPARING HIVES FOR WINTER.

Unfortunately, owing to the untoward season, many are still unfed and uncovered, with supers still on. When it is fair, and the ground dry enough not to chill bees, I shall remove the supers, cover the top of the hive with a woollen cloth, and over that 3 or 4 inches of dried grass; the empty supers will be replaced within the super protector over this grass, and the lid screwed down, but not quite close, so as to permit the perspiration to pass off. The iron roof protects the alighting board, and sides of the hive covering from moisture.

Straw hackles are superior in every respect to cloths generally used, inasmuch as they keep the frost entirely out while they permit a free circulation of air.

LARGE DOORWAYS

I have no faith whatever in. It is a mistake to say, "Nothing tends more to keep bees in health than plenty of air in damp, muggy weather." A solid floor and a wide doorway cause the perspiration to be condensed upon the former, which is instant death to the bee that touches it when the temperature is below 50°. Wax is one of the best non-conductors of heat, and when the combs are within bee-grip of a dry floor their vitality is insured. Not so when it has been impaired by coming into contact with a damp floor, the worst evil bees have to contend with.

DYSENTERY.

One of the most common and fatal forms of dysentery is brought on by lowering the temperature of the hive, which prevents the bees moving about freely and feeding at proper intervals during all weathers. Whenever bees fast too long their evacuations become watery. Wide doorways and damp hastens on this fatal disease.

HOW TO MAKE HACKLES.

It is not so easy making straw hackles by the ordinary method of plaiting, as is by taking a handful of straw, turn a loop upon the top end, then tie firmly with twine. After a sufficient number are made pass a strong cord through the loop or eye, then tie at one corner of the hive, cut the ends of the hackle equal, and a little shorter above entrance; before trimming off tie the hackle

firmly in two places to keep close to the hive. A useful thing in the apiary and the garden is

A HAND BARROW.

To transport heavy hives short distances, such as to a proper site at the Heather, a hand barrow is required. Procure two pieces of timber for shafts, about 6 feet long and 3 by 1½ inches, planed, and the ends dressed for handles. Then two slats of the length required are screwed to the shafts at the proper width to allow a hive to pass through. This is upon the same principle as a parallel rule. When a heavy hive is to be lifted pass it over the top of the hive, and the handles, when it is clear of the latter, raise them, and when the barrow is lifted the hive is suspended. Four short legs should be added to it.

SWARM CATCHERS.

The Americans speak in praise of these, which I have several times described in this Journal. "Ernest," in "Gleanings," says, "With the swarm catchers he was greatly pleased. These, the reader will remember, are to be attached by the apiarist to the entrance of the hive from which the swarm is just issuing." Both the swarm catcher and the hiver are my inventions, and have been in use in my apiary for thirty or more years. So that these, with our system of bee-keeping, should be tried by every beginner, to whom I will have more to say in future articles.—A LANARKSHIRE BEE-KEEPER.

*All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Laelias Decaying (B. B.).—We have received your letter, but the parcel has not yet come to hand, and therefore a reply cannot be given in the present issue.

Ivy-leaved Pelargoniums and Marguerites for Bedding (J. L.).—Mr. Dunkin is requested to give the information you desire, and it will be useful also to other readers. See our instructions to correspondents at the head of this column.

Brown and Green Centred Primulas (J. S.).—Such varieties as you send, also the others alluded to, are to be seen in most large establishments in which a speciality is made of Primulas; and occasionally similar varieties, though they may not be exactly the same, result from packets of seeds of varieties in mixture. These varieties of Primulas are not very popular, nor the plants as a rule imposing in growth and floriferousness.

Evergreen for Hedge (F. L.).—The best evergreen for a hedge is Holly, planted 1 foot apart; but you want the "best and quickest growing," for which combination no plant equals the Evergreen Privet (not the "common," which sheds its leaves in winter), and it should be planted 6 inches apart when the plants are 1 to 2 feet and previously transplanted; but larger plants may be given more room if care is taken to have them near enough to form a good bottom.

Seedling Apple and Grape (E. W.).—The appearance of the Apples, which are more or less cracked, also your reference to the Ribston Pippin, suggest that the roots of the trees are in a medium that does not contain what is needed for promoting healthy growth. The fruits are also attacked with fungus. The trees require cleansing with lime and more support at the roots. Strong liquid manure applied copiously at the present time from the stem outwards beyond the spread of the branches might do much good. The Apple is not considered to possess any special value, and the Grape resembles those imported from Italy by the ton and sold in London for 4d. a pound.

Apples, Pears, and Plums for Table and Kitchen (F. L.).—Apples: Beauty of Bath, Lord Grosvenor, Worcester Pearmain, King of the Pippins, Beauty of Hants (Cobham or Pope's), Cox's Orange Pippin, The Queen, Bismarck, Reinette du Canada, Brownlee's Russet, Baumann's Red Reinette, and Bramley's Seedling. Pears: Doyenné

d'Été, Williams' Bon Chrétien, Beurré d'Amanlis, Beurré Superfin, Louise Bonne of Jersey, Comte de Lamy, Durondeau, Emile d'Heyst, Maréchal de Cour, Doyenné du Comice, Josephine de Malines, and Bergamotte Esperen; stewing: Vicar of Winkfield, Catillac, and Directeur Alphand. Plums: Early Prolific, The Czar, Oullins Golden, Denniston's Superb, The Sultan, Belgian Purple, Early Transparent, Green Gage, Victoria, Jefferson, Kirke's, and Coe's Golden Drop. All are suitable for pyramids or espaliers.

Maggots on Peach Bark (*J. B.*).—This, on examination of specimens, turns out to be the frequent foe of this tree, also of the Apricot and Plum, called Tortrix Weberiana; the caterpillar produces a small silvery brown moth, of which there appear to be two broods yearly, so that the caterpillar is found in the spring and autumn. One of its effects is to cause exudations of gum and the growth of protuberances. It has been recommended to apply with a hard brush a wash of sulphur and lime, or the familiar one of petrolcum and softsoap. Syringing or spraying does not so well remove the pest from the trunks or branches of trees.

Peaches Unsatisfactory (*West Riding*).—It is not uncommon for some varieties of late Peaches ripening in October to have very tough and dry flesh. We have usually found the defect a result of insufficient supplies of water and nourishment at the roots during the swelling and up to the last stages of the fruit ripening, accompanied by an arid condition of the atmosphere caused by drying currents of air. This appears to be your case, the moisture in the atmosphere and the water and nourishment at the roots having been inadequate to the demands of evaporation, which, being excessive, has caused the fruit to become woolly and juiceless. The treatment recently accorded the trees would only aggravate the evil, as the heat with ventilation would increase the evaporation. We can only recommend better supplies of water and nourishment at the roots from the time of the fruit commencing to swell until it is perfected, with a genial condition of the atmosphere. The condition your Peaches are in is more pronounced in light than in heavy soils through the deficiency of potassic matter in the former.

Espalier Trees (*H. W.*).—In forming espalier trees it is important to keep the lower tier of branches longer than the next pair above. If the lower branches are weak elevate them to encourage growth, depressing those above them if these are the strongest. Take care to occupy the lower part of the space with branches; there will be no difficulty in furnishing the upper portion of the trellis. Shorten the leader to 1 foot for originating another pair of side branches as well as a new leader. If this makes early and strong growth it may be cut back after mid-summer, and a second pair of side branches will have time to form by the autumn. This is not always the case, and you must be guided by the vigour of the tree in summer shortening. Espalier trees are commonly too weak at the base, and if the upper tiers of branches grow unduly strong the extremity as well as side shoots may be pinched when about six pairs of leaves are formed, taking a second growth for extension, pinching the others as directed, and subsequently to one leaf as it is made. The sap will then be diverted into the lower branches. It is not a good plan to train the branches horizontally the first year or two, except any that are very strong, for checking exuberance, then the weaker, that are trained more or less upright, will be invigorated, and in time a well-balanced tree will be formed.

Gourds (*F. M. D.*).—The Great Gourd (*Cucurbita maxima*) sometimes produces fruit of an immense size, there being instances on record where they have been grown in this country weighing 212 lbs., and measuring 8 feet in circumference. We have ourselves seen them upwards of 170 lbs. in weight. This and its varieties are always round and depressed, like a much-flattened Orange, with an indentation at the stalk and flower ends, and generally ribbed. The French call it Potiron. It is used in soups. The Pumpkin, or Pompion, called by the French Citrouille, is *C. pepo*. The fruit of this is generally oblong, or inclining to oblong, and very much smaller than the preceding. There are a great number of varieties of it cultivated in gardens, both for ornament and also for culinary use. They are used cut up in soups, in the same way as Turnips are; and they also make very excellent pies, which are much relished by some, the quality depending very much on the mode of cooking. When the fruit is ripe some cut a hole on one side, and, having taken out the seeds, fill the void with sliced Apples, adding a little sugar and spice, and then, having baked the whole, eat it with butter. It may also be used fried in oil or butter. The Squashes so extensively grown in America are *C. melopepo*. They are always flat, and have prominent angles or ribs on their sides; that which is called Turk's Cap, and is variously coloured like a turban, belongs to this species. *C. ovifera* is Vegetable Marrow, now so extensively grown and generally used. Some of the Gourds are entirely covered with large warts, and are called Warted Gourds. They are varieties of *C. verrucosa*, and vary in size and shape, being round, flat, Pear-shaped, and bottle-shaped. The Americans use them, when about half-grown, as a sauce to their meat. The Orange Gourd, which is of the size, shape, and colour of an Orange, is *C. aurantia*, and may also be eaten like the others. When trained up a pole or against a wall, and covered with its beautiful orange fruit, it makes an ornamental plant.

Names of Fruits.—*Notice.*—Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of

approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*J. Gray*).—1, Catillac; 2, Beurré Superfin; 4, Beurré Clairgeau; 5, Bergamotte Esperen; 6, Williams' Bon Chrétien. (*C. Page*).—1, Gravenstein; 2, Blenheim Pippin. (*F. A. J. E.*).—A, Bess Pool; B, Ross Nonpareil; C, Cox's Orange Pippin; D, Golden Reinette; F, Lane's Prince Albert. (*Brynkinalt*).—1, Pear-shaped Quince; 2, Golden Reinette; 3, Dumelow's Seedling; 6, Nouveau Poiteau. The others probably local varieties. (*G. M. S.*).—A, Blenheim Pippin; B, Russet Table Pearmain; C, Fearn's Pippin; D, One of the ornamental Crabs. (*Joseph R. Formby*).—1, Maréchal de Cour; 2, Olivier de Serres. (*J. H.*).—Apple Hollandbury; Pear British Queen. The Lord Suffield are very bright, and the Beurré Rance unusually fine. (*W. S.*).—1, Not Irish Pitcher, more like American Mother; 2, Deux Sœurs. (*R. J. H.*).—A valuable and fine Apple which we cannot identify; you should send six fruits to the Fruit Committee of the R.H.S. (*C. W. Duke*).—Cox's Orange Pippin. (*A. Reid, jun.*).—1, Winter Queening; 2, Nonesuch; 3, Minchull Crab. (*F. Williams*).—1 and 2, Ecklinville, the variation due to stock influence; 2, Petworth Nonpareil. (*G. F.*).—The Apple is Hollandbury; the Pear is Comte de Lamy.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*T. H.*).—1, *Viburnum cotinifolium*; 2, *Leycesteria formosa*; 3, *Cryptomeria elegans*; 4, *Retinospora ericoides*; 5, specimen defective, possibly *Polygonum Sieboldi*; 6, *Liatris spicata*. (*E. H., Cottingham*).—1, *Quercus Cerris*, a variety of the Turkey Oak; 2, *Fagus sylvatica laciniata*, the Fern-leaved Beech. (*J. H.*).—1, *Polygonum*, too far gone to name; 2, *Solidago*, var. of *latifolia*; 3, *Veronica spicata* and var. *alba*; 4, *Echinops sphærocephala*; 5, *Dendrobium chrysotoxum*.

TOWN REFUSE.

A SCHEME of the Corporation of Manchester to purchase Rampton Manor Estate, North Notts, for £60,000, as a receptacle annually of 20,000 tons of the city's refuse, composed of fecal matter, ashes, stable manure, and the detritus of the roads, has met with quite the usual amount of opposition. The only justifiable objection is the possibility of the spread of disease germs in districts through which the trucks laden with the refuse pass, and of the contamination of the Trent by the drainage water from land dressed with the refuse. Surely, the first can be met by the use of proper trucks, and in the second the action of soil as a deodoriser appears to have been lost sight of—at any rate, by opponents of the scheme. Upon the face of it, we might say that with the advanced stage of scientific knowledge, and the host of learned professors among us, means ought to be forthcoming to prevent any possibility of harm. But the Inspector of the Local Government Board and others engaged in the recent court of inquiry into the scheme, appear to hold the opinion of scientific men but lightly. Their view of the matter is evidently just the popular one of getting rid of filth at any cost, without thought of its value as a fertiliser. They ignore the natural law of give-and-take, and of the economical utilisation of waste matter.

In doing so they have no excuse, for it has been emphatically pointed out to them that this huge mass of refuse is a veritable gold mine of plant food of soil fertility. Said a correspondent during the inquiry, "Richness is thrust upon the Rampton estate and spurned. An area of low rates might be converted into high rates. Given proper cultivation, town refuse would make an Eden of this unfortunate poor clay land. Not considering the chemical advantage, the ashes work mechanically in converting stubborn, adhesive clay into friable loam. The Manchester Corporation might turn many honest pennies by buying poor estates at £20 per acre, manure them ten years with their refuse, and sell them for £40 per acre, and then again seek fresh fields and pastures poor." Quite true, every word of it, and yet, strange to say, instead of earnest inquiry and strenuous effort to turn this fertiliser and opener up of the starved soil to account, the evidence of those who wish to prevent it being used, from unreasonable fears of harm to the people, is listened to, and it unfortunately appears to have sufficient weight to possibly defeat the scheme.

Nor is this because other evidence which we know to be entirely reliable was not forthcoming. Dr. Voelcker, consulting chemist of the Royal Agricultural Society, has examined the soil of the Rampton estate, which he described as being of three kinds—stiff, cold, red, marly clay, sandy clay, and, on the low-lying part, river silt and sand. He had no doubt the 1100 acres of arable land would take 20,000 tons of the manure annually, and he thought there could be no limit to the capacity of such land to take 20 tons per acre annually. He pointed out that from the composition of the manure it could be manipulated with forks, it was in no sense liquid; no chemical change would take place in it in transit, and its manurial and mechanical action would be highly beneficial to the soil. If the manure contained impurities the soil would act as a disinfectant. With such a supply of manure there could be no necessity for fallows. "My opinion," said Dr. Voelcker, "about fallow is that it is a waste; there is no reason for fallow at all." "Well, now," said the examiner, "looking to the character of this land and to the quantity and character of this manure, do you see any reason

why the operation should not be a successful farming operation?" "I see no reason, and I think it is the very thing the land wants," was the answer. We may mention that Dr. Voelcker gave his sensible evidence after some "experienced agriculturists" had said in evidence that the land must be fallow, and that it would not take the quantity of manure proposed to be put upon it. He said plainly that they were wrong; we are glad that he did so, and wonder at any men accustomed to the cultivation of farm crops taking part in a movement to keep such manure off the land.

Talk of depressed agriculturists! why, it seems impossible to help them. Here is the Corporation of Manchester with an annual output of 67,000 tons of a manurial substance of the very best kind for storing soil with fertility, and opening it up for air circulation and prompt water filtration; yet, instead of the neighbouring farmers combining to obtain a regular and full supply of it, some of them are found actually to come forward and say a fair dressing of it would be hurtful. Are these the men who cannot make Lancashire farms answer, and are coming south to try their hands on Essex farms? Surely they are incompetent to deal with the Essex clays, for they are clearly ignorant of the first principles of agriculture, which in addition to soil drainage, insists upon thorough mechanical division and a constant replenishment of fertility—plant food in the soil in the form of manure.

WORK ON THE HOME FARM.

Unsettled weather has much hindered work of all kind. There is still much corn out south of the Trent, some of it yet unreaped. This is the case in one or two instances even in Leicestershire, and it is still more so in Derbyshire and Nottinghamshire. Beans are a very late crop this year, and also very unequal in bulk. In the south we have seen some very inferior fields of Beans, but in the midlands there are some excellent crops. Roots are generally good; Mangolds have now about done all the good that is possible, and the sooner the crop is off the land the better in every way. Though much rain has fallen there have been frequent short spells of fair weather, quite sufficient to dry up the surface and render carting an easy matter. Get the Mangold stored and protected from frost at once; the roots will then be safe, the land will be cleared for ploughing, the work will be done briskly and well, and the ploughs got upon the land at once.

These hints really bear upon early autumn tillage. If this had full attention at once as the stubbles were cleared corn sowing would be forward, so would ploughing generally, and land under late crops could be ploughed at once as we have suggested. This of course implies always being forward with farm work instead of behindhand, as is so generally the case.

Let all corn stacks be well thatched and trimmed; nothing can be worse than to leave stacks of Barley and Oats with ears of corn exposed on the sides. This is slovenly and wasteful, and in Barley tends to spoil the sample, for corn so exposed becomes much stained, is dark in colour, and though there is not much of it there is frequently enough to spoil the sample. It is just a trifling matter of detail worthy of attention.

REMARKS.

- 2nd.—Almost continuous rain from 7.30 A.M. to 5 P.M.; cloudy night.
 3rd.—Bright sunshine in morning, spots of rain about noon, and occasionally in afternoon, with sunshine between.
 4th.—Sunny morning, generally cloudy in afternoon, steady rain from 4 P.M. to 8 P.M., and showery after.
 5th.—Overcast and rainy early; damp morning; bright sunshine after 1 P.M.
 6th.—Overcast morning; occasional spots of rain after 11 A.M., and slight showers in evening.
 7th.—Cloudy early; frequently sunny in morning and after 3 P.M.; heavy showers from 1.30 to 2.30 P.M.
 8th.—Fair, with occasional sunshine, but a shower at noon; bright night.
 Another wet week, and considerably colder than the previous one.—G. J. SYMONS.

WE are progressing—steadily but surely progressing—in the supply of home-grown fruit, and the public taste is advancing in the right direction also. A daily paper recently stated that “one of the most pleasant changes in the aspect of London of late years is in the striking multiplication of fruiterers’ shops. A taste for fruit, and a conviction not only of its wholesomeness but of its desirability as a part of the daily food has been rapidly spreading, and all efforts to promote the cultivation of fruit deserve the highest commendation.” Those remarks have reference at this season mainly to Apples—undeniably the most substantial and serviceable of all our hardy fruits, though the Pear supply cannot be ignored.

Not only are fruiterers’ shops increasing, but what is not less important is the marked improvement in the produce displayed. The different emporiums where the best samples obtainable are presented have never been so well furnished before as they have been of late, and are now, with British Apples—not grown abroad, but at home. This is not the case in London alone, but in most of the best shops in provincial cities and towns. It is not less true, however, that by far too many and too large consignments of inferior “stuff” are forced on the markets; but the days of this untempting or almost repulsive apology for fruit are numbered. Just as well grown high-class fruit increases in bulk, so must the inferior be elbowed out of the market, for those who send it in will find no returns for their ventures in a very few years; indeed not a few persons are finding this out now, and naturally grumble accordingly. They grumble at free imports, grumble at railway charges, grumble at agents’ commission, grumble at the advice given in the press to plant trees, and so on; in fact, find fault with everything and everybody, but leave the greatest evil of all untouched—their own negligent methods and slovenly ways.

Granted that there is room for improvement in transit charges, there is hope that railway directors will be compelled to mend their ways and develop trade; and admitting the fact that there are unprincipled sharpers among the great army of commission agents, yet among fruit brokers there is no lack of honourable men who conduct their business in all respects as fairly as the best and most successful traders in other commodities conduct theirs. Without saying anything against the efforts that are made to bring producers and consumers of fruit closer together, but, on the contrary, rejoicing in whatever is accomplished in this direction, we suspect the fact will have to be recognised that the enormous bulk of produce grown in the country for meeting the demands of the million in towns will have to be distributed through the channels of intermediaries, just as bread and butter, tea and sugar, jams and pickles, are through the agency of shopkeepers. Competition compels these to reduce profits for increasing trade, and those dealers in fruit who act on the same principles of moderate commission charges, just methods, and prompt payments are developing their trade enormously, and profiting accordingly, while not a thought is entertained of their “fleecing” the grower. This upright dealing and its manifest advantages will compel others to adopt the same methods, or they will lose their custom, and eventually be driven from the markets like bad Apples.

Growers of a few hundredweights or even tons of Apples can no more deliver them to distant consumers than the owners of coal mines can distribute their black diamonds among the homes of the people; but no doubt something can and will be done in the disposal of fruit by local arrangements when the number of small cultivators and the high quality of their wares justify the effort. Apart from the certain increase in jam and bottling manufactories for taking the soft fruits of districts and distributing them all over the civilised world, as we ought to do with our natural advantages for production and preparation, local combination will be formed on the basis of Mr. Ivarts’ scheme in Cambridgeshire. He added fruit growing to his ordinary farming operations, and finding the change good extended his plantations. Then he took out a broker’s licence for selling his own fruit in the great emporium Stratford Market, not of course objecting to sell the fruit of others. Eventually he arranged to collect all the fruit of small growers in his locality at 2d. a bushel, or something of that kind, including its conveyance three or four miles to the station, send it up with his own goods at truck rates, and sell it on commission, giving to each grower a statement of the full amount realised and his charges, both clearly shown. This method proved of mutual advantage. It would be impossible that the several small cultivators could dispose of their crops anything like so well by independent action, if at all, with profit. The plan has answered so well that, though the district is flat and bleak, fruit plantations are seen on every hand, and small home plots filled with trees and bushes. Cottenham is, so to say, a parish of small holders, and not many villages can boast better homes of workers and present a cleaner and more general well-to-do appearance. Mr. Bull, one of the most intelligent fruit growers there, has referred to the district in these columns, and he speaks in tones of gladness of what fruit-growing has done for the community among which he resides. The wholesale condemnation of intermediaries for the disposal of fruit and garden produce is a fashionable fad. They are a necessity, and systems should be established whereby they may become helpful aids, working on recognised lines, the whole of their transactions being open and above board, so that the growers of fruit know exactly what is being done—the amounts realised, and the charges incurred in its disposal.

There is no doubt whatever that the market standard of home-grown Apples has been raised, and those who send in the best produce, honestly packed and attractively presented, have no difficulty in disposing of their crops at remunerative prices. Such men do not spend their time in grumbling at low prices for mixed samples, mostly bad, but in working for good ones, which alone can give a satisfactory return. Nor can the finest of Apples be had in any other way than planting young trees of wisely chosen varieties in well prepared soil, and giving them intelligent attention. Regular and systematic planting will have to be pursued in the future if Britain is to hold its own in Apple production. Neither salesmen nor consumers ask or care where fruit is grown, they simply want and will have the goods which are considered the best worth the money, and the best Apples in the market now are home-grown.

The season of late has in most parts of the country been favourable to young trees for planting. A bright September promoted maturation, October rains (too heavy and prolonged in some districts) have moistened the ground, and the “plants,” as they are called, ought to “take up well” when the time comes. Let the whole subject of planting be promptly considered and the line of action determined; also let orders be given as soon as possible. If the early bird catches the worm in anything it is in the ordering of trees, for in no other way can early planting, which is so desirable, be ensured. Avoid “cheap bargains,” large trees with few roots, and let market bundles alone. The trees may or may not be true to name, and may or may not grow fairly well; but the risk is too great to hazard. The safe

course, in the end the cheapest and always the best, is to purchase from growers of high and acknowledged reputation in the fruit tree-raising centres of the United Kingdom.

JOTTINGS ABOUT FLOWER BEDS.

As each bedding season draws to a close it is well to take note of the behaviour of the various subjects used, to see how far the climatic conditions peculiar to each summer influence the growth and effectiveness of them; also to record any arrangements found to be specially attractive. The past season has on the whole been a fairly good one for the inmates of the flower garden, notwithstanding the fact that we experienced several slight frosts in June after the greater part of bedding out was completed. By the middle of July the beds were well filled, and in many instances in full beauty. This was especially noticeable when close planting had been adopted. There can, I think, be no doubt about the wisdom of this practice, considering how short and uncertain our summers are. Take the past season as an example. Those who were unable through lack of plants to plant closely have had to be content with beds which were in full beauty for only a very brief period, for although the autumn frosts have not, at the time of writing, yet played havoc among them, the weather has been so dull and sunless, with occasional heavy rains, that flowering plants of many descriptions have striven in vain to show their charms.

Our beds of Zonal Pelargoniums were this season, for special reasons, planted unusually thick, and we have many times since been glad of it. They not only produced a mass of flower early in the season while the weather was favourable, but the plan also enabled us to obtain good cuttings without spoiling the appearance of the beds. I am strongly in favour of using numbers of old plants. They are easily wintered, flower earlier and more profusely than young ones; and if pegged down at planting time quickly form an even regular bed. John Gibbons and Vesuvius are, I believe, the best scarlet bedders grown, and I know of no crimson one to equal Henry Jacoby. The trio are so good that no one should be disappointed if they depend entirely upon them to supply the two colours named. I have this year discarded Mr. Atkinson on account of its being a very strong grower.

Among Ivy-leaved Pelargoniums, Madame Crousse and Souvenir de Charles Turner have again proved great favourites with all who have seen them. Those who have not yet tried these fine plants as summer bedders should make a point of doing so next year, for I feel sure they will be delighted with them. The last-named does not flower quite so freely as Madame Crousse, but this is amply compensated for by the fine bold trusses and very large pips produced. Another great recommendation for Ivy-leaved Pelargoniums is that young plants can be easily preserved during the winter, as it is very rare indeed that they suffer from damp. Almost every cutting inserted may be depended upon to grow, while long leggy plants which have become useless for pot culture may be turned to a good account by planting them in beds, and pegging the shoots in any direction required. Marguerites associate effectively with these plants if dotted at intervals of 4 or 5 feet along the centre of oblong beds, filling in the groundwork with Ivy-leaved Pelargoniums, and providing a suitable edging. Mrs. Perry Pelargonium or Pyrethrum Golden Feather each answer the purpose admirably.

Although at times the weather experienced during the past summer has been dry and hot, yet Calceolarias have throughout done remarkably well. This convinces me that the so-called disease which causes Calceolarias to die off may be easily combated if the young plants are grown sturdily throughout the winter and planted out early in rich well prepared soil.

Tuberous Begonias are useful bedding plants, which we cannot well dispense with. To grow them well, however, they must have plenty of water in hot weather or the flowers drop very quickly. When carpeted with Sedums the effect is particularly good, and the flowers are kept clean, but I find the Begonias thrive much better when a bed is entirely devoted to them, and for that reason cannot recommend the Sedums to be planted among them.

Viola Countess of Hopetown is I consider the finest white flowering plant grown, either for spring or summer bedding. Four beds of this variety in the flower garden here were planted in November last, and to-day (Sept. 24th) the plants are still flowering freely. The growth made is much shorter-jointed than is the case with most other varieties, consequently they flower for a longer period before requiring to be cut down. The majority of other Violas seemed to have grown and flowered to the extremity of their shoots by the middle of August; when they have arrived at this stage only a few straggling flowers will afterwards be produced on the old shoots. They should therefore be cut down, which will have the effect of causing the young shoots springing from the centre of the plants to grow quickly. These will in due time flower freely,

though only in exceptionally mild seasons this will not take place till the spring months.

The beds they occupy may, however, be quickly made gay again with the aid of Asters if a sufficient stock has been prepared for the purpose. A few beds I have this season treated in the following way have throughout September been very attractive. A good batch of Asters were pricked out in June 6 inches apart, and as soon as the Violas were cut down they were lifted, divided, and planted in the reserve garden. The beds were then deeply dug and the Asters lifted with a good ball of earth and planted in the prepared beds; a thorough watering was then given, and an occasional one when necessary afterwards. These beds have proved quite an attraction. Asters are very accommodating plants and bear transplanting wonderfully well; in fact, they may be safely lifted when the flower buds are beginning to burst, and if the work is carefully done the check experienced will be scarcely perceptible.—H. DUNKIN, *Castle Gardens, Warwick.*

DISCUSSION ON APPLES.

APPLE BEAUTY OF HANTS.

As "E. M." has referred to this variety I should like to state what I know of its origin. Some years since, when in the gardens of Glen Eyre, Southampton, Mr. Stewart, the gardener, drew my attention to a tree heavily laden with fine fruits of what seemed to be a superior and much more conical form of Blenheim Pippin. Trees of the latter growing close by gave very diverse products in growth and fruit. The tree was regarded as a Blenheim seedling raised in a nursery near Southampton, and from whence it was obtained. The Apples were so fine, rich coloured, and distinctly conical—quite as much so as King of the Pippins—that I asked Mr. Stewart to send a sample to the Fruit Committee of the R.H.S., which he did, and we gave it the appellation of Beauty of Hants. The fruits received, I believe, a first-class certificate, and the variety was put into commerce from Heatherwell, Bagshot. It may be, perhaps, that everyone has not got the real thing, or that under ordinary culture after working it has been found to be but a variety of the Blenheim.—A. D.

WALTHAM ABBEY SEEDLING.

WHEN I went to reside at the seed grounds, Bedford, Middlesex, I found there several trees of Apples, each perhaps some twenty years planted, of the Ribston Pippin, Alfriston, Wellington, Cockle's Pippin, and Waltham Abbey Seedling. The soil is a very stiff clay. Alfriston soon died, as the points of the shoots refused to ripen. So also have those of Ribston Pippin, although the tree still fruits moderately. Cockle's Pippin has always been a stunted tree, and Wellington, for the past ten years, has done badly, and rarely borne a respectable crop. But the Waltham Abbey Seedling has never changed, except to grow somewhat larger. There never has been a year since 1871, when it first came under my notice, that the tree has not produced fruit more or less in quantity. It has never shown any evidence of canker or decay. The head of a broad, yet compact, drooping character, and none too high. I regard this Apple as one of the very best to recommend for cottagers as a regular cropping kitchen variety, for the fruit always cooks admirably, and keeps well till March.—A. D.

VARIETIES FOR CLAY SOILS.

KESWICK CODLIN is an abundant bearer every other season with me, does not make much growth, and generally forms plenty of fruit buds. Lord Suffield is similar to the above as to growth and bearing qualities, but cankers badly. Scarlet Admirable, Alexander, Hoary Morning, and Nonesuch are sure bearers here every year if they escape injury from frosts. Blenheim Orange, Warner's King, and Yorkshire Greening rarely fail to produce a heavy crop of fine handsome fruit. The last-named grows very straggly, but the fruit will keep in good condition till the following May. Warner's King is a particularly clean grower, and the fruit always very large.

Regarding dessert varieties, King of the Pippins, Cox's Orange Pippin, Cockle's Pippin, Nonpareil, and Quarrenden are sure bearers, especially the two first named varieties. The trees are young, and make clean, healthy growth. The fruit had to be severely thinned early in the season, and the branches supported later to prevent breakage through the weight of fruit which they carried. Quarrenden has a very heavy crop in alternate years. The trees, which are all standards and bushes, are never pruned hard back, but where the boughs appear to be at all crowded some of them are sawn out close to the main branches, and the wounds finished with a sharp knife; a few of the longest shoots left have the ends cut off. The fruit buds form on nearly the full length of the branches, which are invariably laden with fruit like "ropes of Onions." Nearly all the varieties of Apples grown here have a very rich

colour. I think the heavy clay soil has some influence upon them in regard to this: For this district I can confidently recommend the varieties named to planters, and if the trees are planted on the level ground, and moulded over instead of being put deep down into water pits where clay soils have to be dealt with, canker will not be so troublesome.—G. GARNER, *Amberwood, Christchurch.*

CELLINI.

THIS variety is a case in point of how some sorts vary in different localities. Mr. Brotherston in his interesting notes, p. 287, says "Stirling Castle and Cellini for heavy soils only." Now with me in a heavy soil this variety is quite the worst we have; both a standard and bush tree of it have never given us a quarter of a crop during the last twelve years they have been planted, although this season there is more fruit than at any time previous. I have heard it said that this Apple will not succeed in the extreme south, it is more of a cooler district sort. How far this may be true I cannot say, but hereabouts I have not seen a tree which carried a full crop, while in Yorkshire it used to bear abundantly. Certainly where it does succeed it is an excellent variety. Not only are the trees shy in bearing, but they canker very badly in spite of repeated liftings and the addition of new soil about the roots.—E. M.

POTTS' SEEDLING.

I FIND this variety does not succeed here in our soil; the fruit is plentifully borne, but the skin is much specked and spotted, the foliage is too pale in colour. Perhaps by replanting this variety on a mound I shall succeed better with it. At Benham Park, Newbury, there is a very fine half-standard tree of it growing in the frame ground, apparently without any particular attention to its roots, and it crops plentifully, the fruit being of excellent quality.—E. M.

BAUMANN'S RED REINETTE.

FROM the appearance of the fruit of this variety I should say this is likely to make a splendid market Apple for the winter supply. The colour of the fruit quite equals Worcester Pearmain, and that is greatly in its favour, this being by far the most important point to study in market Apples. The size of the fruit appears to be what market people require; it is not the largest that are the most in demand, but those which are the most handsome. The habit of growth is upright, another point in its favour. Presumably this Apple crops freely in ordinary seasons.—E. M.

GOLDEN SPIRE.

THIS is a capital kitchen Apple to grow where space is somewhat limited, or in any garden where a full crop of fruit is needed about the middle of September. This Apple is much longer than it is wide, hence its name. The colour is an intense golden colour, more so than any other early variety I know. The growth of the tree is rather weak, necessitating supports being placed to the branches when carrying a heavy crop of fruit.—E. M.

FUNCTIONS (AND WEIGHT) OF VINE LEAVES.

MOST assuredly a smile, amounting very probably to a broad grin, overspread my countenance on reading what Mr. John Swan had to say on the question of stopping the lateral growths of Vines. Mr. Dunkin will have to search far and wide to find anything half so effective in the shape of an instance of what has been done by an advocate of the practice of leaving several leaves beyond the bunches. It is my firm belief that a few extra well-developed leaves are of more importance to the well-doing of the Vines, both above and below ground, than three times the quantity of crowded, thin, and otherwise imperfectly formed, or even moderately strong foliage. Sub-lateral growths I value but little, as they can never do the work of the thick, leathery, primary leaves, such as Mr. Swan appears to have on his remarkably heavy cropped Vines. There need be no apprehensions of failure in the case of the latter, at any rate not till a distinct warning in the form of weakly foliage is given.

Mr. Dunkin derives the grounds for his arguments from various sources, and he is quite welcome to adopt all and sundry that he can so find, a roving commission being accorded him. He quotes what has come under his notice in a few cases, but directly I turn the tables on him I am told that my reference is exceptional and inglorious. To a certain extent it is inglorious to make a point at other people's expense, and I should not have said so much as I did had there been the slightest possibility of my remarks hurting the feelings of or doing an injury to the individual most concerned. My contention was that a comparatively unrestricted lateral growth did not prevent a great falling off in the weight and value of the crops, but I knew too much about the whole matter to even insinuate that it was wholly to blame for the failure. At the

same time references to failures had for obvious reasons better be left out of this discussion, and for the future I will confine my remarks wholly to what is taking or has taken place under my own management.

What should be adopted in the case of Vines in perfect health need not nor ought to be the same as when they require renovation; but Mr. Dunkin is confounding the one with the other. When I first undertook the charge of the old vineries here the Vines were in a wretched plight, and one of the renovating measures practised with a fair amount of success was the laying in of a number of young rods, a few of these being laid in every summer for years past. Mr. Dunkin remembers seeing some of these, and jumps at the conclusion that my practice is very different to what I advocate. What little success I have met with in horticulture has been largely due to the avoidance of any hard and fast lines, and also because I have profited by many blunders made by myself and others. This season I stopped some laterals at several leaves beyond the bunches, very many more at the second leaf, and sufficient to test the soundness of previously formed views as to the effect of close stopping or otherwise. Not till Mr. Dunkin has done the same is he fully competent to prove that what I have previously stated is altogether wrong, and no amount of "beating about the bush" will meet the case. The house of late Grapes I referred to on page 304 as being in extra good condition at the end of ten years has been of an experimental character from beginning to end, and chapters might, in fact, have been written on what has been done. Never once were the Vines allowed to form any superfluous growth, and never once have they failed to do well. This season the crops are heavy, the bunches fairly large, and the colour has been termed "perfect" by several good judges. As yet very few bunches have been cut, and I shall be only too pleased to show the rest to Mr. Dunkin or any other reader of the *Journal of Horticulture*. All the rods are clothed with lateral growths down to the ground, and what is not often seen bunches are hanging within 6 inches of the border. In all probability the bunch of Gros Colman on a hard-stopped lateral, mentioned on page 304, will be the best in the house, and I hope it will find its way to Mr. Dunkin's county next month. It may be thought that the border in which those Vines to which I point with so much boastful pride was exceptionally well made; but I can safely say that it was extremely cheap, the material consisting of clayey loam cut from a bank in a poor meadow and the top spit of our garden soil in equal quantities, mortar rubbish and the residue of a garden "smother" being freely added. Bone manure has since been used with the top-dressing material, but none was mixed with the original compost. To all appearances those Vines are improving in health and vigour, and a very great change will have to come over them also in my ideas before any superfluous growths or leaves will be left.

There is no good reason, that I can see, why my old friend Mr. Bardney should not fully state his views on the subject under discussion, whether these be in accordance with mine or not; and now the evenings are longer, and gardeners have more leisure time, it is to be hoped more of them will give their experience. It is not to be expected that we shall all agree in the matter, but a good-tempered well-conducted discussion not unfrequently brings out instructive comments, that otherwise would not appear in print. Why I did not state the "something else" necessary to ensure perfect colouring of Grapes is because I have already frequently done so in these pages, and I will now merely add that my practice corresponds closely, as far as free ventilation is concerned, with that very lucidly described on page 305. Mr. Bardney has well pointed out the secret of success in colouring black Grapes at any rate, and that too whether the Vines are hard or only lightly stopped.—W. IGGULDEN.

It is not a pleasant task to demolish the cause that brings a "happy smile," but I am afraid Mr. Iggulden's newly found cause for happiness will be as fleeting as it has been beaming; at any rate, I think there is no difficulty in showing that his would-be supporter from across the border has in reality weakened the cause he intended to support. I thoroughly agree with Mr. Swan that "good leafage is of primary importance, and that the higher the development of foliage the more perfect will be the elaboration of the sap and its assimilation by the Vine." But when it comes to the question of how to produce the type of foliage we both believe in, I will have the temerity to show him how such powerful elaborators of sap can be grown by another and a better way than that which he points out on page 326, a way by which similar leaves to those which he forwarded to the Editor can be grown, not for a few years only, but for ten, twenty—nay, thirty years.

On the day that I received the *Journal* containing Mr. Swan's note I forwarded to 171, Fleet Street, a few leaves taken from Vines growing in the gardens here, the heaviest leaf weighing 1½ oz. and each of the others exceeded in weight those sent from

Mansfield. These were cut from Vines fifteen years old, the variety being Black Hamburgh. The Vines in this house and two others in the same range have been vastly improved in a few seasons by growing plenty of foliage, in many instances there being four and five leaves beyond the bunch, lateral growth also being allowed to extend freely. No liquid manure nor artificial fertilisers have been applied during the last two years, but now that plenty of active roots have been made feeding will in the future have attention. The whole of these Vines have this year carried a crop which many cultivators would think they could not possibly colour. Neither would they have done so if the shoots had been stopped in the way Messrs. Iggulden and Swan advise. Several of the Vines in question are now carrying 50 lbs. of perfectly black Grapes, and in one case I believe the weight will reach nearer 60 than 50. The heaviest bunch on this Vine weighs about 6 lbs.

The weight of crop produced on the young Vines under Mr. Swan's charge is a really good cultural achievement, provided the Grapes were well coloured. That is the vital point. It is all very well to state what has been done with young Vines when closely stopped for a few years. The boundless vigour of youth enables them to build up strength and produce good returns, not because of, but in spite of, unnatural suppression; but let this close stopping be continued for ten years, then what is the result? Are not Vines in a feeble state incapable of perfecting anything like the weight of crop they should do? Another point which Mr. Swan seems to have overlooked is that up to the present time root action, and consequently good leaf production, has been fully maintained by the continual growth of the leaders of his Vines. This has more than compensated for the close stopping of the laterals. Thoughtful readers will see at once that he weakens rather than strengthens his cause by drawing comparisons between Vines, Cucumbers, and Melons. There is so little analogy between them; the last two being grown as annuals their permanent welfare has not to be considered, and in the case of Cucumbers old growths are being continually cut away and young ones laid in.

Mr. Swan must have been content with very poor crops of Cucumbers, if by close stopping he can obtain "double the quantity of fruit off a given space." Any individual who can show so simple a way to double the produce, and therefore at least treble the profit on the growth of this popular edible, confers a real benefit upon the entire community, a benefit which should establish his fame at once, and quickly lead him on to fortune, if the tempting bait he holds before our eyes does not vanish like a bubble and leave no trace behind. In regard to Melons I am well aware that the fruits will swell to a large size if no growth is left beyond it, but the practice is a thoroughly bad one to follow as a regular detail of culture. Numbers of plants carrying fine crops of Melons utterly collapse every year just as the fruit begins colouring, for the simple reason that root-action is sluggish on account of persistent stopping, and even when they manage to ripen their fruit after a struggle the really fine flavour and deep flesh of a well-grown Melon are absent. At no stage of a Melon's growth should the whole of the spring shoots be stopped. The extension system of growing Melons may not be so well adapted to the requirements of gardens generally as that usually practised, but Mr. Iggulden is well aware of the great superiority in the flavour and the depth of flesh obtained in Melons cut from plants which give a succession of fruit throughout the season.

In conclusion I will express the firm conviction that the surest way to induce Mr. Swan to join the ranks of those who believe in the extension system of Vine growing, is to ask him to persistently follow the close stopping system with his Vines which have begun so well. In the course of a few years he will then have to do one of three things—be content with inferior Grapes, allow greater freedom of growth, or root out the Vines and plant fresh ones.—H. DUNKIN.

[The five leaves sent by Mr. Dunkin weighed $6\frac{1}{2}$ ozs., the heaviest turning the scale at $1\frac{1}{2}$ oz. This is the heaviest Vine leaf we have yet received. The leaf stalks were also slightly thicker than those of Mr. Swan. The increase in weight of the leaves from Warwick Castle was due to their greater expanse—14 inches against 12—and they were not quite so thick and dark in colour as from the young Vines. Their weight, however, indicates their substance and power. They are wonderful leaves as perfected by old Vines and undoubtedly good management.]

EDUCATION IN GARDENING.

EARLY in the present year we announced our intention of presenting a limited number of large silver medals to gardeners for the best essay on gardening subjects proposed to them through the secretaries of the respective horticultural or mutual improve-

ment societies of which they are members. The results have been very satisfactory. Two of the essays sent in were so good that we unhesitatingly awarded medals for both of them. On opening the envelopes containing the names of the writers one of them proved to be Mr. Thomas Garnett, The Gardens, St. John's, Wakefield, and the other Mr. E. D. Smith, Walkley, Sheffield. We have pleasure in publishing the photograph of Mr. Garnett as the senior essayist. He has long taken interest in educational matters, and has read papers before the Wakefield Paxton Society, of which he is co secretary with Mr. Fallas. Mr. Garnett is a close student, an excellent practical gardener, and a worthy and respected man. We publish this week the first instalment of his essay on "Education in Gardening," and on its completion that written by Mr. Smith will follow. The latter essayist is a comparatively young man, and may be expected to contribute worthily to the literature of gardening.

MR. GARNETT'S ESSAY.

BRITISH horticulture is what our best practitioners have made it, a subject worthy of our pride in it. The practical work and its splendid results, as exemplified in our best gardening establishments, apparently leaves little room for any better system of education and training of gardeners; but in this age of educational progress we cannot afford to remain stationary. Degrees of efficiency amongst individuals are inevitable, and we are compelled to admit that there are many gardeners who do not take special interest in the profession. When once they have been taught to do the work to their way of thinking nothing further is required. This is simply practical work, which makes no progress in any direction. Gardeners and gardening are bound together so that when any improvement is made in either both must progress. It is the inert unleavened mass that requires moving, and we shall have to trust to the educational lever on the coming generation of gardeners to push horticulture on to the higher level to which it is capable of attaining.

The open road to this progress lies in the direction of an education, blending together the best possible acquaintance of the present with the more exact knowledge of those laws which govern plant life. Call it science or call it common sense. The progress and developments made within the last few years in plant physiology affecting the very spirit of gardening opens out wide fields of advancement in methods and results, which it would be folly to ignore. To the general present-day gardener the word "science" is a well-known bugbear. But this arises from hasty conclusions on the relationship of practice to theory. It goes without cavil that as scientific, or what is understood by gardeners as theoretic knowledge, becomes disseminated and acted upon, it gradually passes over into the region of practice. It is utter folly to boast of practical knowledge and yet to persistently ignore the fact that it is neither more nor less than proven theory emanating from scientific deductions.

That the general principles of gardening emanating from this source are on a sound basis is abundantly proven by the high state of perfection to which gardening has attained. We may therefore safely take it for a rule that our most successful gardeners are those who consciously or unconsciously are working out in their everyday practice the laws which govern plant life, as interpreted by our eminent plant physiologists. Who, knowing anything of this subject, dare predict the results which may be achieved in the future when the general body of gardeners becomes leavened with this knowledge, supplemented by the present and improved methods accruing, of imparting information to each other? In making these propositions we know there is a limit to the acquirement of such knowledge by the most persevering students, but to do so and apply the lessons to be derived from it does not require, as many seem to think, that the gardener shall become a walking encyclopædia of all the sciences. The wave of public opinion on elementary and technical education which has swept like a tide over the country, culminating in the passing of the last Education Act, which, supplemented by liberal grants from County Councils and other authorities, the employment of lecturers on "Horticultural subjects," and now the inclusion of "Horticulture" on a wide and comprehensive basis as one of the specific subjects in the last issued "Government Education Code," is broad and sound enough to be used as the stepping stone to the higher education needed to this end. We are now on the threshold of a new era in horticultural progress, and thus any discussion throwing light upon the subject at this juncture ought to prove of especial value.

SUBJECTS TO STUDY.

Hitherto the working class population has been the natural and general source of the supply of gardeners. It must be admitted, therefore, that those drawn from this source are likely to possess in a superior degree the requisite characteristics best meeting and suiting

the special circumstances connected with the environment of the gardener's calling. We are under these circumstances constrained to base any scheme of education and training of gardeners adaptable to the greatest number, on the assumption that what has proved to be the rule in this respect in the past will still obtain in the future.

It is under exceptional circumstances that a lad leaves school before he reaches his fourteenth birthday. If of medium intelligence, under ordinary tuition he will be capable of passing his fifth standard examination at eleven years of age, when he is at liberty to take up as part of his studies "specific subjects." His education so far will have covered the elements of reading, elocution, grammar, writing, composition, drawing, arithmetic up to simple proportion and simple interest, geography, including causes affecting climate, and history. Coming now directly to the "specific subjects" allowed by the Education Department, we have to consider those which have a direct bearing on his future studies and particular calling in life, attempting to indicate the easiest gradient by which he may reach the goal for which he is striving. The new subject, "Horticulture," as a matter of course, in importance must take precedence of the others. As yet no class book on the subject has been published, and we are somewhat in the dark as to what extent the teaching of the subject will carry him, but this book is bound to follow. Taking the Education Department syllabus as our guide it carries on the face of it sufficient to indicate a fair elementary course of plant physiology. It so fully covers the subjects to study that we cannot do better than quote it in extenso.

HORTICULTURE.—PLANT LIFE.

"FIRST STAGE.—Seeds, nature of, germination, requirements, water, heat, air.

"Soils.—Nature and composition; what they do, and how. What helps, and what hinders them.

"Roots.—Nature and functions; branches, fibrils, and root hairs.

"Stems and Branches.—Their nature, work, and uses; helps and hindrances.

"Leaves.—What they are, what they do; helps and hindrances.

"Buds and Tubers.—Leaf buds, flower buds, and tubers.

"Growth.—Increase in size, and changes of composition; formation and storage of food materials.

"Flowers.—Their component parts; what they do.

"Fruit.—Changes and development; ripening. Forms and varieties of—as Apple, Strawberry, Plum, &c.

"SECOND STAGE.—Elementary Operations.—Description, and use of implements, under each head. Operations connected with the land, with explanations of good and bad methods. Digging and trenching, draining, hoeing, stirring the soil, and weeding. Watering. Preparation of seed beds, rolling and raking, sowing, transplanting, and thinning. Potting, planting, position, and shelter. Staking, earthing, and blanching. Propagation: elementary principles, cuttings, budding, grafting. Insects and fungus pests.

"THIRD STAGE.—Advanced Practice.—Budding, grafting, and stocks used. Layering, division, branch-pruning; root-pruning, old and young trees and bushes. Fruit culture: open air and under glass. Small fruits: Apples and Pears. Stone fruits: gathering and storing, packing and marketing. Vegetable culture; tubers and roots. Green vegetables. Fruits and seeds (Peas, Beans, &c). Rotation of crops. Flower culture: open air and under glass. Manures and their application. Treatment of insect pests. Treatment of fungus pests. General knowledge of fruits."*

This syllabus covers the practical details of garden work generally, but the first stage is of especial value, showing that all the operations have underlying their performance definite reasons why they are, or should be done, animating the purely practical with the very spirit, of which the former is but the embodiment. The close inter-relationship of this part of the subject with certain branches of "physiography" will be evident. A school course of this epitome of the sciences will prove of especial value in clearing the way of the difficulties in understanding the technicalities, &c., involved in the advanced studies of botany especially referring to "plant physiology," chemistry, geology, atmosphere, weather and climate, work and energy, heat and light, are physical phenomena involved and resultant, playing a most important part in "plant life." As much of each of the above branches have a bearing on the question—viz., chemistry, a knowledge of the elements and compounds, their affinities, and chemical formula and symbols. Geology, the nature and composition of the rocks, as the source of important elements (inorganic) of plant food, the part which rocks play in the formation of soils, &c. Atmosphere, its composition, measurement, height, density, temperature, and hygrometric conditions. Weather and climate, causes affecting climate. Work

and energy, in relation to the sun as the source of energy. Heat, its nature, source, measurement, effects on liquids, solids, and gases, evaporation and radiation. Light, its effects on vegetation.

A course of elementary chemistry would enable the student to grasp in their proper order the leading principles involved in relation to the elements of plant foods, the economy of manures, and a knowledge of plant physiology covered by the advanced stage in botany which should follow in due course later on.

It would be of immense advantage to our intended gardener if he could possibly remain at school until his fifteenth birthday, so that besides passing the sixth and seventh standards he would have a year longer to carry out concurrently along with his usual standard work the specific subjects named. In regard to teaching facilities, in urban and suburban districts there will be no difficulty found; even in the rural districts, at the present rate of progress, not many years will elapse before all schoolmasters are abreast of

FIG. 47.—MR. T. GARNETT.

the "economic sciences." The same remarks apply to languages, and the gardener's education cannot be called complete unless he knows sufficient Latin to understand the names of plants and the botanical terms used.

(To be continued.)

FRUIT TREES AND FRUIT.

AMONGST KENTISH FRUITS WITH MR. GEORGE BUNYARD.

IF *pomum redivivum* be good Latin, of which, the Latin-learning days being in the long ago, I am a little doubtful, it might be inscribed with a double meaning over the portals of the great nursery which Mr. G. Bunyard directs with such conspicuous ability and success near the pleasant old town of Maidstone. His great practical knowledge, foresight, acumen, and courage have done much to further the revival of British fruit growing; while years before the movement in which he has taken a prominent part gained force he had revived the drooping fortunes of an old-established house by the same admirable qualities. In looking over the magnificent collection of fruit exhibited by him at Earl's Court the lesson was learned that what he has advocated with voice and pen he proves to the hilt by actual produce, and those who in face of the conviction piled on conviction's head during the past year or two still persisted that fruit could not be produced in a large bulk equal to imported specimens must have received a rude shock. Perhaps they supported themselves with the assumption that the splendid Apples exhibited were all picked examples, grown on highly fed established trees under glass, hence large in size, polished in appearance, and rich in colour. And as people in general are just as ready to base an elaborate argument on a hasty assumption as on a well established fact, they would be able to reason themselves into a state of considerable pessimistic comfort. But what are the facts? Something quite different, believe me. A visit to Maidstone arising out of the Show referred to, whereat a great desire was engendered to see the conditions under which fruit is grown in Mr. Bunyard's nursery, shows that the magnificent fruit staged was gathered, not from established highly fed trees under glass, but from

* Abstracted from Schedule of Specific Subjects.—Ed. Code.

young specimens growing under ordinary conditions in an extensive nursery.

THE ALLINGTON NURSERIES.

The principal nursery, for there are more than one connected with Mr. Bunyard's great business, is that adjoining Barming Station on the L.C. and D. railway, reached from London *via* Sevenoaks. It comprises 96 acres, of which about 16 are under seeds and Potatoes, 30 under Roses, shrubs, and Conifers, and 50 under fruit trees. A goodly sight it presents on a brilliant October morning, and its condition is such as may be viewed with admiration by visitors and with pride by the proprietor. The trees are in serried ranks, thousands upon thousands; but, although the rows represent a length of many miles, weeds are conspicuous only by their absence. Everywhere order, cleanliness, and good culture are observable. Miles of healthy, thrifty trees betokening the practical cunning of the guiding hand. They are in perfect condition, vigorous but sturdy, with clean stems, perfectly developed leafage, and, in many instances, a crop of fine fruit, albeit gathering time has cleared many of their burden.

Just such pleasure as is experienced in looking over a well-kept flower garden—the beds well furnished, the lawn even, the borders neat—is felt in following Mr. Bunyard over his splendid nursery, and noticing the prevailing features. What other than a garden is it, though it run to scores of acres and contain no flowers save a few adventitious fruit blossoms? Who will say there is no beauty in long ranks of Apple trees, some ruddy with fruit, but all bright, clean, and healthy? There is abundant variety about them too, even when fruitless, for each has its peculiarity of foliage or growth. Here is the somewhat meagre leafage of Stirling Castle, which forms fruit buds as it grows and therefore advances but slowly; there are the thick stems and hold substantial leaves of Bramley's Seedling, bearing very well on the Paradise here, though in heavier soil its one fault of tardy fruitfulness becomes apparent. Mr. Bunyard knows them all. He goes through acre after acre, picking out one after another. They are like familiar children to him. When their fruit is off he knows them by their leaves; when the leaves are off no doubt he knows them by their stems, and I should not like to say that if they were cut down he would be puzzled by the roots, for there the question of stocks comes in, and if anyone knows stocks well it is he.

TWO-YEAR-OLD BISMARCKS.

There was one sight in the nursery at the time of my visit not soon to be forgotten, and that was a quarter of Bismarck two years old bearing three to six enormous fruits of the richest colour. They were from 2 to 3 feet high, and very striking. What was particularly noticeable, too, was the fact that they were by no means stunted by their precociousness, but have made vigorous and healthy growth during the past season. Superb dishes of show fruit have been picked from these young trees, and there is not the slightest doubt that had it been marketed high prices would have been realised. We do not see much imported fruit of the weight, size, and colour of that gathered in abundance from Kentish soil. I do not know what Mr. Bunyard's stock of Bismarck amounts to, but it must be an extensive one, and finer trees than those which compose it it would be hard to imagine. It would be difficult to speak too highly of the great Australian. In every respect it is an Apple of the highest class. It is a free and healthy grower, bears early and heavily, does well both on the Paradise and Crab stocks, is not delicate as to soil, and the fruit—which is large, heavy, and handsome—keeps well. It is a culinary variety, that has essentially come to stay. Order Bismarck and order early, for last year the report on every hand was "sold out," and this year the demand will be still greater. Sterling Apples like this will sell—sell, I mean, both as trees and as fruit. The big Kentish market growers are after it, and will not be denied. They scent money in it, more, perhaps, than there is in the "Ecks," Grosvenors, and other of their reliables. Time will settle this point, but be sure that whatever its ultimate position as a market variety may be it is a grand garden Apple, and to be without it is to be behind the times.

OLD AND NEW APPLES.

Mr. George Bunyard is blessed with more than average length of limb, and being now happily restored to health his stride is long and vigorous, so that anyone who can keep going with him at his best pace will see much in a couple of hours' hard exercise at the Allington nursery. And he is a good guide, thoroughly at home among his trees and full of information about them. Old and new varieties pass in review. Here is Bismarck, the pride of the nursery, as I have said, and there a fine quarter of Lane's Prince Albert, splendid on the Paradise for hush work, but rather slow in running up as a standard, hence established on the Kentish Goff. There is one magnificent break of about 14,000 trees, comprising two or three popular varieties, on the Paradise, without a weakening among them, but all healthy and vigorous. Then we observe the Hornead Fearmain, a dessert or cooking Apple, not sufficiently grown, being of good quality and an excellent keeper. Grenadier is in splendid condition also. Is this good Codlin going to make headway? Bramley's Seedling on the Paradise is striking, for it is bearing a fair crop of handsome fruits. New Hawthornden and Potts's Seedling are grown in enormous quantities, for these admirable Apples are in great demand. Lady Sudeley hears out what Mr. Bunyard has recently told us in the *Journal*—namely, that it must not be pruned hard. It is conspicuous, like Golden Noble, for the bareness of the lower part of the stems, and bears towards the tips of the shoots. Evidently it will be best suited by being left alone when pruning time arrives, except for thinning. This beautiful Apple is likely to become popular, for it is of

very agreeable quality, and has soft, digestible flesh. It is an excellent early variety for eating from the tree. It will make a splendid free pyramid, and should be ordered.

Summer Golden Pippin or Yellow Ingestrie, which, by the way, does better grafted than budded, is in much demand as a market variety, and is largely grown, for its beautiful little fruits sell well. Wealthy makes itself conspicuous by its rich and brilliant colouring. It is another of the Apples that are likely to grow in favour, and may be eaten either raw or cooked. Almost the same remarks apply to Baumann's Winter Reinette, a beautiful Apple, and the tree a fine bearer. Three-year-old Dutch Mignonnies are loaded with fruit. Cornish Aromatic, a dessert variety of sprightly quality; Cox's Pomona, large and finely coloured; Gascoigne's Scarlet Seedling, a beautiful Apple and a free bearer, raised near Sittingbourne; Gold Medal, a culinary variety, large and good-looking; Okara, a distinct and well-flavoured Swedish Apple; Peasgood's Nonesuch, of which magnificent examples have recently been shown; Royal Jubilee, a new and promising culinary variety, well worthy of trial; and the Queen, represented by some splendid fruits, are but a few of the others that are noticed.

TRAINED TREES.

Gridirons and toasting forks are useful household implements, while pitchforks prove their serviceable character elsewhere. All have their counterpart in the trained trees at Maidstone. We see Apple "gridirons" for the side of walks, where they serve the same purpose as espaliers, differing from them in having upright shoots springing from a horizontal tier instead of having several tiers of horizontals one above the other. Then we observe Pear "toasting forks," dwarf trained with three upright branches; and Pear "pitchforks," which have two uprights, and are admirably adapted for the pillars of walls. Amongst the Apples, however, nothing was more striking than the "amateurs' standards," which are on the Paradise stock, half and full length stems. They are feathered with fruit spurs from base to summit, and could be fruited, cordon-like, on the stems until the branched heads came into bearing. These are recommended for private gardens where a combination of standard trees and prompt bearing is required. The fruiting bushes on the Paradise are also admirable trees. They are trained with six or more branches springing from the base and wide apart, so that sun and air can have full play, and if the foundation thus laid in the nursery is followed up an admirable type of trees is secured. They are clothed with fruit buds, and ready for bearing next season. There are plenty of small bushes to be seen, about 4 feet high and 3 feet through, planted 6 feet apart, bearing from twelve to twenty splendid fruits. Espaliers with two, three, four, and five tiers are grown in abundance. Then there are espalier-trained trees for walls and cordons, both single and double, upright and horizontal, Apple and Pear in great numbers. Of these either young trees to be grown into a fruiting state, or specimens studded with fruit spurs can be had. So far as securing trained trees is concerned it seems to be merely a question of ordering, for they are ready in all sorts, shapes, and sizes, admirably trained, clean, in robust health and vigour.

THE FRUIT ROOM.

A grateful odour of ripe and ripening Apples—that piquant and mellow aroma which is so agreeable and refreshing—betrays the occupants of a heavily thatched structure in the open nursery. The fruit room is a very simple structure, and could be imitated cheaply. It is constructed of match-boarding, both top and sides, and thoroughly thatched from base to summit. Wire gauze ventilators at the top and sides insure a pure stream of air. The room is now a splendid sight. The broad shelves laden with the splendid fruit, which secured Mr. Bunyard a silver-gilt medal at Earl's Court, present a significant and instructive spectacle. Here, indeed, is proof eloquent and conclusive of what English soil and English culture can do in the production of high-class fruit. It is not one variety alone, developed by special treatment, that gives such noteworthy results. The varieties number scores, grown under no other conditions than good soil, pure air, and general nursery management of a sound and practical character. The door of the fruit-room is open to visitors, so that all may learn the lesson that is conveyed by it, and those who have fruit they want naming can bring it for comparison with the Maidstone fruit. The extreme care that is taken to keep all varieties true to name admits little chance of error. "We are mortal," says Mr. Bunyard, "and therefore not infallible, but all that can be done to keep things true we do."

THE OTHER NURSERIES.

A pleasant drive from Allington to Maidstone takes us to the home nurseries, a cluster of seven small places with about fifty houses. This is a surprise to many who fall into the way of classing Bunyard & Co. as fruit growers only. The florists' department is both extensive and well kept. Then there are spacious shops and offices for the seed business and clerical work, a landscape gardener's office and other conveniences. Besides these there is the Chiltern Nursery of eighteen acres where the Strawberries are grown, also shrubs and forest trees, in which the trade is by means small. Telephone communication connects all the chief centres with the head office, which is close to the S.E. railway station at Maidstone. Space permits of no further reference to the nurseries, but they are open to visitors from all parts. They teach a much-needed lesson of good management and of the benefits that accrue from soil culture, cleanliness, and plain wholesome fare. When the sound methods that characterise the work of George Bunyard and his lieutenants become widely imitated there will be great hope for fruit-growing at home.—W. P. W.

TEA-SCENTED AND NOISETTE ROSES FOR CUTTING.

MANY varieties of sterling merit have during recent years been added to our lists of Tea Roses. This must tend to make them increasingly popular, and will doubtless have the effect of causing them to be grown even more extensively, for there are very few places in which the supply is equal to the demand. Without having any intention to write disparagingly of the merits of Hybrid Perpetuals, which are extremely beautiful in their way, it is nevertheless well to note the fact that very few ladies would choose a bloom of one in preference to a well grown Tea Rose. The delicious perfume, characteristic form, and exquisitely shaded colours of Tea Roses give them a beauty of their own which compels instinctive admiration; yet in many gardens of pretension, where the former are grown by the hundred, a few dozens only of the latter are cultivated in the open air. True, this may be accounted for to some extent by the comparative tenderness of Teas, but after making due allowance for that it seems somewhat strange that it should be so when there are so many sheltered positions in gardens in general where these great favourites would grow and flower to perfection. Plants on their own roots may also be safely grown as bushes in beds and borders if 3 inches of leaf soil, cocoa-nut fibre, or short strawy manure are placed around the stems before severe weather sets in. When this precaution is taken, although the wood may in very severe winters be killed to the ground, the roots, or rather the stem, will again send up strong suckers, which will give good blooms late in the season.

Early in November last year I planted against a low south wall the following varieties:—Adam, Innocente Pirola, Souvenir d'un Ami, Safrano, Caroline Kuster, Hon. Edith Gifford, Anna Olivier, Madame Lambard, Rubens, Ernest Metz, Ma Capucine, Comtesse de Nadaillac, Madame de Watteville, Perle des Jardins, Princess of Wales, The Bride, Madame Riza du Parc, Bougère, and Souvenir d'Elise. When the planting was completed, leaf soil to the depth of 3 inches was placed around each bush, so as to form a mound about 18 inches in diameter. Notwithstanding the severe winter which followed, every bush grew, and only one among the number had the wood killed to the ground, this being that reputedly tender variety Madame de Watteville. Strong suckers were, however, sent up in the spring which produced several good blooms during August. Perle des Jardins and Ma Capucine have grown wonderfully well and produced a surprising number of blooms. Even now (October 8th) I have counted from nine to twelve promising buds on several of the plants, and if we escape sharp frosts for another week, most of these buds will be sufficiently advanced to be cut. The first named of these two varieties has a delicious perfume, and good blooms, almost equal in appearance to Maréchal Niel. Considering its hardiness and high quality I consider Perle des Jardins to be one of the very best among Tea Roses. Ma Capucine has one defect—viz., very little scent. The buds, however, are of exquisite form, and the colour coppery yellow. This variety is especially suitable for supplying beautiful buds late in the season. Both The Bride and Innocente Pirola are good growers and produce exceptionally fine flowers. The first named, like its parent, Catherine Mermet, throws up strong shoots, which are surmounted by a number of fine buds. This variety, for form, substance, and purity, is the best white Tea grown. Hon. Edith Gifford, with its salmon-rose centre, supplies a colour which finds many admirers. The flowers are very large and full, but are not so freely produced as is the case with some varieties. Madame Lambard is a most useful and telling variety. The bright red colour of its flowers is one which is much wanted. Among Teas, on that account, it should be freely planted; it is, moreover, one of the most hardy and floriferous of its class. In some soils and positions the flowers come much paler in colour than in others, the best coloured ones being produced on plants growing in a heavy staple.

Adam and President are, I think, too much alike for both to be included in a collection. They are moderate growers, and produce their salmon-coloured flowers freely. Bougère is another very fine Rose for cutting, and, although not bearing many flowers at any particular time, is scarcely ever without a few. Souvenir d'Elise is, I think, one of the very best and most beautiful. Princess of Wales has proved the weakest grower among our collection. It is greatly admired when the buds are in a half-opened stage, the colour then being rose-yellow, which is both novel and attractive. Comtesse Riza du Parc is a variety not much grown, but it is a most useful one for supplying a quantity of cut blooms of a metallic rose colour. Almost everyone knows of the great value of Celine Forestier as a wall Rose, but few are aware that it is so thoroughly hardy. We have several bushes growing in a very exposed position which have withstood the severe cold of the last two winters, with the loss of only a few small shoots.

Old trees of Homère and Ophire on walls have throughout the summer given us a wealth of lovely buds, such good growers and free flowers as these two are indispensable where quantities of Tea Roses are required. Safrano fleurs rouges, like its well-known relative, is beautiful in the bud, flowers freely, and somewhat resembles Madame Lambard in colour. Madame Berard is a very strong grower, being good for covering arches and high walls. The flowers are similar to those of Gloire de

Dijon, but of a brighter colour. When cut, however, they do not last so long as those of the latter variety. William Allen Richardson and Reine Marie Henriette are two grand varieties, useful alike for growing both indoors or out, as also are Niphotos and its climbing form.

I find Tea Roses are valuable for affording flowers during September and October, as well as during the summer months; but to do them justice in the autumn a good deal of attention should be bestowed upon collecting and preparing them for that special purpose. I make a practice of collecting any buds which are beginning to open every afternoon. Some of these are not very attractive in appearance when gathered on account of the outer petals being browned by wind and rain. These are removed, and where practical the remaining petals loosened with the handle of a budding knife; the flowers are then placed in warm water and kept in the fruit room for twelve or twenty-four hours, during which time they open considerably, and are then ready for decorative purposes. They last several days and develop into full blown Roses. Anyone who has not hitherto done so will do well to give this little extra attention to Roses whenever the weather is unfavourable for their development.—H. DUNKIN.

PLAGIARISM.

WE have received the following letter, which we do not hesitate to publish; and regret extremely that an evidently able man should have allowed himself to appropriate and use as his own the experience and literary work of Mr. Barron. In the conditions attaching to the production of essays for our silver medals it is made imperative that every quotation used should be indicated in inverted commas and the source fully acknowledged, and that every book from which knowledge is gained shall be mentioned. This is only just and fair to authors, and our desire is to discountenance all such literary immorality as is represented in this case.

MR. BARRON'S LETTER.

Permit me to direct your attention to a report of an essay on "Grape Vines and Their Cultivation," read at a meeting of the Devon and Exeter Gardeners' Association by Mr. McCormick, which is almost a word for word extract from my book "Vines and Vine Culture."

I have no objection to Mr. McCormick or anyone else making copious extracts from my work; indeed, I take it as a compliment, but in all fairness he ought to have acknowledged the source of his knowledge, and not try to sail under false colours.

You will see by the copy I have marked, the extent of the cribbing I complain of, and as I note it is "to be continued," I must ask you to inform Mr. McCormick that I object, and I shall demand of him a suitable apology.—A. F. BARRON, Author of "Vines and Vine Culture." *Entered at Stationers' Hall.*

MR. BARRON'S BOOK.

Chop the turves with the grass and fibre roughly to pieces, and to 5 or 6 cubic yards of this material add 1 yard of old lime rubbish or broken bricks, a portion of charcoal, wood ashes, or burnt soil. . . . Those ingredients, well mixed, will constitute the main body of soil, . . . but is subject . . . to considerable modification as to proportions, according to the quality of the loam . . . If the loam used is of a sandy nature, less of the lime rubbish must be used, as the object . . . is . . . to give porosity to the soil. If, on the other hand, it is of a clayey nature, a much greater proportion of lime rubbish will be required.

In many places it may be very difficult to obtain soil at all approaching that which is here recommended, but let no one despair of cultivating Grapes on that account. Vines will grow, and grow well, in soils of a much inferior nature under careful management.

Manures.—For the growth of Vines nearly all soils require the addition of some fertilising ingredients. . . . Not very many years ago it was the popular belief and custom in the formation of a Vine border to bury the carcasses of animals—such as horses, cows, &c.—in the border, under the mistaken idea that the roots of the Vines revelled in such putrid matter; a more stupid idea never existed. At the present time very

MR. MCCORMICK'S PAPER.

I advise chopping the turf with the grass and fibre roughly to pieces, and to 5 or 6 cubic yards of this add 1 yard of old lime rubbish or broken bricks, a portion of charcoal, wood ashes or burnt soil; these well mixed will constitute the main body of the border, but are subject to considerable modification as to proportions according to the quality of the loam. If this be of a sandy nature less of the lime rubbish must be used, as the object in employing it is to give porosity to the soil. If, on the other hand, it is of a clayey nature a greater portion of lime rubbish will be required.

In many places it may be very difficult to obtain soil at all approaching that which I have recommended, but let no one despair of growing Grapes on that account. Vines will grow well in soils of a much inferior nature under careful management.

MANURES.—For the growth of the Vine nearly all soils require the addition of some fertilising agent. Not very many years ago it was a popular plan to bury the carcasses of animals such as horses, cows, &c., in the borders, under the mistaken impression that the roots revelled in such putrid matter. A more erroneous idea never existed. At the present time very different notions prevail in regard to manures, and also the making

different notions prevail in regard to manures, and also the making of Vine borders. Some of the best cultivators now have their soils analysed with great care, and the different ingredients, of which they may be found deficient, added with mathematical precision.

In the formation of a Vine border which is intended to be of a permanent nature, the manures that may be used should be of a lasting character, so that they will afford support to the Vines as long as possible.

Size of Border.—The Vine may be grown in a very small space, and in a very little soil, as is evidenced by the splendid results obtained by its cultivation in pots. . . . If permanent Vines are desired—Vines that will continue in full vigour for, say, twenty years—a border of considerable size must be provided. . . . Many good cultivators form their Vine borders in sections—i.e., 3 or 4 feet is made up the first season, a similar portion is added the following year, and so on, until the required space is filled.

Inside v. Outside Borders.—Much discussion has taken place as to . . . having the Vines planted inside . . . or in borders outside the house. . . . The disadvantages are . . . The great amount of labour, &c., required in watering, and the skill and care necessary in keeping up the requisite degree of moisture at the roots. A scarcity of water, or a little neglect in its application, will ruin the crop. On the other hand, outside borders require little attention in regard to watering.

Drainage.—This is one of the most important operations in the formation of a Vine border, and one that, in some situations, entails a considerable amount of expense and trouble to render it efficient. It is a point that must always be taken into consideration in selecting the position for a vinery. . . . It is better to take all ordinary precautions at the first, rather than to run any risks, and then, after several years of loss and disappointment, to have all the work to do over again.

In every case, therefore, a considerable amount of draining material should be placed over the whole surface of the bed of the border—say from 1 to 2 feet or more in depth.

In the formation of a Vine border, it will thus be seen that every contingency ought to be taken into consideration, not only the position or situation, but also the level of the border itself. The amount of excavation necessary in making up the border will be determined by its depth, measuring from the surface-level; thus a border raised 2½ feet requires only to be excavated to a depth sufficient to hold the drainage.

Covering.—It has long been customary that Vine borders should be at all times covered with some fermenting material. It is, however, not necessary in ordinary cases. The beneficial effects of the frost on the soil is well known, and it is good practice to expose the soil of a Vine border to its action as much as possible.

of Vine borders. Some of the best cultivators now have their soils analysed with great care, and different ingredients in which they may be found deficient added with mathematical precision. In the formation of a Vine border which is intended to be of a permanent nature the manures that may be used should be of a lasting character, so that it will afford support to the Vine as long as possible.

BORDERS.—Vines may be grown in a small space and in very little soil, as is evident by the splendid results obtained by their cultivation in pots, but they are soon worn out; one crop one season and they are done. If Vines are desired that will last for twenty-five or thirty years borders of considerable size must be provided, and this is best done in sections. If young Vines are to be planted 4 to 6 feet will be found sufficient to make up the first season, adding a similar portion as the roots extend, and so on until the space is filled up.

Much discussion has taken place as to having the Vines planted with the roots inside or in borders outside the house. . . . The disadvantages are the great amount of labour required in watering, and the skill and care necessary in keeping up the requisite degree of moisture at the roots. A scarcity of water, or a little neglect in its application, will ruin the crop. On the other hand, outside borders require little attention in regard to watering.

DRAINAGE.—This is one of the most important matters in the formation of a Vine border, and one that in some situations entails a considerable amount of trouble and expense to render it efficient. It is a point that should always be taken into consideration in selecting a position for a vinery. It is better to take all ordinary precautions at the first rather than run any risk, and then after several years of loss and disappointment to have all the work to do over again. A considerable amount of draining material should be placed over the whole of the bed of the border—say, from 1 foot to 15 inches in depth, and certainly never less than 9 inches. . . . In the formation of a Vine border everything ought to be taken into consideration, not only the position, but also the level of the border. The amount of excavation necessary in making up the border will be determined by its depth, measuring from the surface level; thus a border raised 2½ feet requires only to be excavated to a depth sufficient to hold the drainage.

COVERING BORDERS.—It is an old custom, and I think considered by many to be needful, that Vine borders should be covered, but I do not now think it is necessary in ordinary cases. The beneficial effects of frost on soil are well known, and it is a good practice to expose the soil of a Vine border to its action as much as possible.

More Vines are ruined through want of water, perhaps, than from any other cause. The quantity of water which Vines require in well-drained borders is astonishing. . . . Before the Vines are started into growth, every particle of soil should be thoroughly saturated, and from the time they come into leaf until the ripening of the fruit.

WATERING.—More Vines are ruined through the want of water than perhaps any other cause known. The quantity of water a Vine requires when growing in well-drained borders is astonishing. . . . Before the Vines are started into growth every particle of the soil should be thoroughly saturated, and from the time they come into leaf until they begin to ripen the fruit.

We decline to publish the remaining part of Mr. McCormick's paper. It is good, as it ought to be, as it contains a great deal of matter from Mr. Barron's book, but wholly unacknowledged. The foregoing extracts in paralleled columns are sufficient to show that Mr. Barron is justified in demanding a suitable apology from Mr. McCormick.

— **EVENTS OF THE WEEK.**—The forthcoming week will be exceptionally quiet so far as metropolitan horticultural events are concerned. There will not be any exhibitions held within the metropolitan area, but several important sales will take place. Attention might also be drawn to a five-days sale of nursery stock, which will commence on Monday, 24th, at Hare Hill and Brox Nurseries, Addlestone, and likewise to a sale of Orchids and stove plants at Bristol on Tuesday, 25th. For particulars of these and other sales see advertisement pages.

— **THE WEATHER IN LONDON.**—Although it by no means opened favourably, this week promises to be fine. Sunday proved dull and gusty with occasional showers, but it has since been clearer though cold. At the time of going to press the barometer is firm and sky clear, with north-westerly winds. A slight frost occurred on Tuesday night.

— **THE WEATHER IN THE NORTH.**—With 6° of frost on the morning of the 12th, 3° on the 17th, and 9½°, with very dense hoar frost, this morning (18th), we have had our foretaste of winter. Fine cold weather for the last ten days has enabled the farmers in this locality to secure nearly all their grain. Small quantities of Beans are still in stock. Potato lifting has begun, but these are not grown to any great extent here. In many parts of the country things have not been so favourable. From Berwickshire a friend writes:—"There are hundreds of acres out in this county, even on good soils. As for the Lammermoor farms the crop is quite green, and they are just cutting it. The weather is cold, and scarcely a day is dry throughout. What with low prices for stock and a bad harvest farmers, especially hill ones, are to be badly set this season."—B. D., *S. Perthshire*.

— **COMPLIMENTARY DINNER AND PRESENTATION TO MR. WILLIAM MARSHALL.**—A number of gentlemen associated with Mr. Marshall in carrying out the series of flower shows in connection with the International Horticultural Exhibition at Earl's Court, as judges and exhibitors, entertained Mr. Marshall at a dinner in the Exhibition building on the 13th inst., Mr. Harry Turner acting as Chairman, supported by Messrs. J. Laing, H. Herbst, P. Barr, W. Poupart, A. F. Barron, H. Williams, A. Turner, J. Walker, B. Wynne, R. Dean, &c. In the course of the evening the Chairman presented Mr. Marshall with an oil painting by Miss Macfarlane, representing a Spanish vase containing flowers of *Brassavola Digbyana* and *Cypripedium barbatum*, with a bloom of the *Gloire de Dijon* Rose lying at the base, the picture having been purchased by contributions from a number of friends. Mr. Marshall, who appeared to be much gratified by the compliment paid him, suitably responded.

— **THE SPINDLE TREE.**—Please state in your next issue of the Journal the name of the enclosed specimen I found in a hedge surrounding a coppice, and had been laid with other undergrowth to make the hedge. It is not common here (near Holmwood, Surrey), only a few plants are to be found at long intervals. The natives of the locality call it the "Skewer-wood." I am almost sure it is a deciduous shrub; its berries, or seeds, are very ornamental.—B. G. [The shrub is *Euonymus europæus* or Spindle Tree, which grows freely in many localities. The sprays, with their scarlet fruits, are very attractive, and particularly appropriate to vase and table decoration at this season of the year.]

— **FRUIT AND THE LORD MAYOR'S SHOW.**—We have heard that a movement is on foot having for its object the representation of the fruit-growing industry, &c., in the Lord Mayor's Show on November 9th.

— **PROFESSOR H. MARSHALL WARD ON FUNGI.**—Professor H. Marshall Ward, F.R.S., of the Royal Engineering College, Cooper's Hill, is giving a course of ten lectures at University College, London, on "Morphology and Physiology of Fungi and Schizomycetes." The course began on Thursday, October 13th, at 3 P.M., and will be continued at the same time each week till Christmas.

— **SPIDER WEB SEDUM.**—Having noticed the remarks made by "D., Deal," on this interesting Sedum, preserving its spider web like appearance when covered with glass, I may say that I keep several clumps under glass. Those covered with plain clear glass are by far the prettier, the other under cut or carved glass scarcely showing the webs.—W. T.

— **A PANSY SOCIETY.**—The formation of a Pansy Society is, I am told, under consideration. Admirers of the Pansy may deem this a step in the right direction, but personally I question its advisability. What do others say? The matter, I believe, is in the hands of Mr. George McLeod of Chingford, a well known amateur Pansy and Viola grower.—NOMAD.

— **PEACHES ON OPEN WALLS IN THE NORTH.**—I can endorse what Mr. Campbell says regarding the possibility of growing Peaches in the open air. I have gathered Peaches from the open walls from the last week in July till the present time, October the 10th. I find Early Beatrice a good variety for the open wall.—G. KNIGHT, *Conyngham Hall, Knaresborough.*

— **BOUVARDIAS.**—These most useful plants are looking exceedingly well at Messrs. Veitch's nursery. They are the most sturdy plants I have ever seen, and some of the varieties are now a mass of colour. Purity Beauty, Elegans, Jasminiflora, Vreelandi, President Garfield, President Cleveland, Mrs. Garfield, Alfred Neuner, Mrs. Robert Green, and Vulcan, are amongst the best.—H. W.

— **THE WEATHER DURING SEPTEMBER AT RIPLEY, YORKS.**—This month was, on the whole, very favourable, and in consequence the greater part of the corn in the neighbourhood was harvested. Wind was prevalent, culminating in a gale on the 27th. The rainfall was light, being only 1.06 inch, which fell on thirteen days, the greatest daily fall being 0.22 inch on the 1st. Mean reading of the barometer, 29.93. Mean maximum temperature, 60.9°; mean minimum temperature, 37.5°; mean temperature, 49.2°; highest maximum temperature, 71° on 10th; lowest minimum temperature, 27° on 5th and 30th.—J. TUNNINGTON.

— **A NEW SUGAR CANE.**—A new variety of Sugar Cane is stated to have been discovered in the Upper Niger region of Central Africa. It is described as "a giant variety, possessing great saccharine richness, and capable of being readily reproduced from seed, which in this variety is well developed." Several inquiries have already been addressed to Kew in regard to this cane, and it may be well to state at once that there are grounds for believing that the plant mentioned is not a Sugar Cane at all, but the ordinary Guinea Corn or Sorghum (*Sorghum vulgare*), which is widely distributed over Africa. This plant, it is well known, yields a useful syrup, and strenuous efforts are being made in the United States at the present time to extract a granulated sugar from it. Should the Niger plant prove to possess any special merits as a Sorghum, we shall no doubt hear more about it. It can have, however, little or no interest to the tropical sugar planter.—("Kew Bulletin.")

— **VIOLA PETER BARR.**—This new Viola has been awarded three first-class certificates in the north this year, and is certain to become a very popular variety. Many readers of the *Journal* will recollect having seen it exhibited by Messrs. Dobbie & Co. of Rothesay at the Royal Horticultural Society's meeting at the Drill Hall on September 20th. It is a Columbine-like flower with a yellow centre, lightly rayed, bordered with a heavy belting of bronzy pink; and as I have grown it this year I can vouch for it being quite novel, distinct, and a good grower. It will be sent out by Messrs. Dobbie & Co. in 1893. Novel as the bloom appears the history of the variety is equally as curious. It was raised by Mr. Peter Barr at his nurseries at Thames Ditton from seed supplied by Mr. J. D. Stuart, Belfast. I intend to lay claim to its introduction into commerce, as I had the pleasure of selecting it as the only novelty in a bed of several thousand seedlings.—GEO. MCLEOD, F.R.H.S., *Chingford.*

— **THE LINNÆAN SOCIETY.**—At the meeting of the Linnæan Society of New South Wales on August 31st, Mr. H. Deane, Vice-President, who occupied the chair, referred to the loss the Society had sustained by the death of Mr. R. D. Fitzgerald, well known for his knowledge and for his artistic delineations of Australian Orchids.

— **AMASONIA PUNICEA.**—This is a charming and rather uncommon stove plant, and is well worthy of far more extended culture. It remains in flower for three or four months during the summer, but the fogs of autumn have a most disastrous effect on it, causing the curious yellow flowers to fall very rapidly. In the country, away from smoky fogs, it would doubtless flower over a much more extended period.—H.

— **DEATH OF MR. R. BULLEN.**—We regret to announce the sudden death of Mr. Robert Bullen, the Curator of the Glasgow Botanic Gardens, on the 4th inst. He was well known as a horticulturist, being especially successful in the cultivation of Orchids. The post vacated by his death is one of the best of the kind in the country, and we understand that the appointment will rest with the Corporation of Glasgow, who took over the management of the Botanic Gardens in 1891.

— **HYACINTHUS CANDICANS.**—This charming bulbous plant has been seen to advantage in many of the metropolitan parks this season. At Finsbury Park some large circular beds of it have attracted considerable attention all the summer, whilst in Dulwich Park huge clumps on the borders have been most conspicuous. It is a beautiful plant, and should be more extensively grown in masses in private gardens. Being hardy and of tolerably easy culture there need be no difficulty in getting it established on borders.—C.

— **HARVEST OFFERINGS.**—In noting the excellent purpose to which the Vicar of Shirley had devoted the offertory at his church on Thanksgiving Day, you throw out a hint, "Go and do thou likewise." May I be permitted to say, in justice to my brother parsons, that in very many of our parishes the offertory, wholly or in part, is given (as in my own parish) to the Farmers' Royal Benevolent Institution, which I think perhaps even a more appropriate object in the present depressed state of British agriculture. The list of applicants is something appalling, and it increases every year, and I know of nothing more worthy of help from all who have the means than this most excellent and long-established Society.—D., *Deal.*

— **DAHLIAS IN KENT.**—It might be thought, after reading the paragraph in last week's issue, page 328, that Dahlias had all been cut off in the south, while those in the north were as good as ever. Perhaps our Scotch friends think that Kent and Scotland have had their geographical positions reversed, or that the temperature had been playing us cruel pranks in the south. Nothing of the kind. Mr. Cocker, of Aberdeen, told me last week his Dahlias had been blackened three weeks before. Not only are our Dahlias lovely, but even Heliotropes, Tropæolums, Begonias, and Alternantheras are looking quite fresh, and of which we send specimens.—H. CANNELL. [Such a wealth of fresh, bright flowers of various kinds could only have been gathered in the absence of frost.]

— **THE MARGARET CARNATIONS.**—Unless there are rival claimants for the honour of having introduced the Margaret Carnations these flowers originated, not in Germany, as Mr. W. Dean supposes, but in Italy. The nurserymen who claim to have introduced them state that the "tall" Margaret Carnations were introduced in 1883, the "semi-high" varieties in 1889, and the "dwarf double" or "Tom Thumb" varieties in 1890. The name is given by the firm in question as "*Dianthus caryophyllus Margaritæ fl.-pl.*," the title "Margaret Carnations" being given in honour of the Queen of Italy. Are we to adopt the French form of the word and spell it "Marguerite?" Why not use the English "Margaret," as the introducers have done in the English translation of their catalogue? The experiments at the Spark Hill Nurseries show that there is a great future before this class of Carnations, and it may be of service to some who contemplate working upon them with a view to their improvement, to state that seed in separate colours of the tall varieties may be obtained; among these being striped varieties. I have no precise information as to the parentage of the Margaret Carnations. It is supposed, however, that they are the result of a cross between a border Carnation and one of the varieties of *D. Hedewigi*. I think something might be done in the way of improvement by beginning afresh. I do not find these Carnations do well in this locality unless the seed is sown early in February, or if sown later pushed on in heat. Unless this is done they do not come into flower in the open the same season.—S. ARNOTT, *Dumfries.*

— CUT FLOWER TRADE IN LONDON.—The report of the Flower Girls' Mission states that the trade in cut flowers in London amounts to £5000 a day. Although this includes the profit of the florists, a large amount of this sum still remains to be accounted for by the earnings of the flower girls.

— ABOUT ANTS.—It is well known that ants harbour a variety of other insects in their nests, particularly Gamasid mites; and Mr. A. D. Michael, from a study of ants in Corsica and at Innsbruck, has come to the conclusion that the ants willingly tolerate the presence of the Gamasids, and even protect them. The mites are found to ride away on the backs of the ants when the nest is disturbed; and sometimes the ants carry off the mites and their young just as they do their own. Mr. Michael thinks the mites repay the ants for their hospitality by removing the bodies of their dead, which they devour.

— POTATOES.—The crops with us are very satisfactory, the yield being good and not one diseased tuber, the results being the same on medium and heavy soils. We do not plant many varieties, but good breadths of Sharpe's Victor, Veitch's Improved Ashleaf, Mona's Pride, Snowdrop and Magnum Bonum, the last mentioned being the most unsatisfactory cooker amongst them. Snowdrop, on the other hand, is an excellent cooking Potato, as also it is a cropper. The rows of the two last named are 3 feet apart and the yield is better than when planted closer, yet I cannot induce some of our allotment men to adopt this system; they seem to think that the more sets put into the ground the better the crop must be, but they are wrong.—J. TUNNINGTON, *Ripley Castle Gardens*.

— THE FRUITERERS' COMPANY.—One of the few surviving customs of old London was observed at the Mansion House on Wednesday evening, the 12th inst., when the Fruiterers' Company made their yearly presentation to the Lord Mayor. In remote times the municipal authorities levied a toll in kind upon all the fruit that was brought into the City. Their right to do so was far from being acknowledged by the vendors, who, however, had no alternative but to pay the tax. Eventually, after a long series of acrimonious disputes between the two bodies, a sort of compromise upon the point was come to, the Lord Mayor waiving his claim in return for a free offering of good will in the shape of ten bushels of Apples every October. Neatly packed in new white baskets, covered with spotless napkins, the fruit was gravely borne from Farringdon Market to Guildhall by a procession of porters in single file, headed by the Company's beadle in his gown. On the baskets being emptied a bottle of port was placed in each for the good of those who had brought them. In course of time the tribute came to include the best procurable samples of the various fruits in season, and the presentation was made an occasion for entertaining the court of the Company at dinner. Now that the guild, like so many others, has gradually ceased to have much or anything to do with the trade it continues to represent, some well-known firm of fruiterers are employed to make up the gift, the cost of which, including gratuities to the Lord Mayor's servants, amounts to about £25. It is understood that the present beadle of the Company has seen no fewer than 57 of these annual ceremonies.

— THE LORD MAYOR ON THE FRUIT QUESTION.—At the dinner which followed the above presentation, the Lord Mayor, in proposing the toast of the evening, "The Worshipful Company of Fruiterers," said that the guild was not one of the wealthiest institutions of its kind in London. Its merits, however, were to be judged rather by its deeds than by its position. Most of them know something of the good it had done in the way of furthering the interests of fruit culture in this country, especially since Sir James Whitehead had taken part in the work. The exhibition of English-grown fruit in the Guildhall two years ago had not been forgotten, and but for an accident there would have been a much larger show this year. In all probability one would be held in 1893. The progress of fruit culture in this country of late had been such that even the extensive Guildhall would be insufficient for the purpose, and they might have to resort to the larger area of the Thames Embankment. This progress was due in a large measure to the Fruiterers' Company, which set a noble example both to the poor and the rich guilds of London. England had various industries, but he thought that more depended upon agriculture than any other. Horticulture was closely allied to it, and, as far as they knew, horticulture had not yet received sufficient care and attention. His experience as a hunting man taught him that the weakest fence in the poverty-stricken acre of many homesteads was the orchard; there were twenty gaps there for one elsewhere.

— RATS EATING GOOSEBERRIES.—It would seem that rats at Milnthorpe, Westmoreland, have found a fresh outlet for their predatory impulses. A correspondent says that the ripe Gooseberries in his garden there were disappearing very rapidly this year, and he supposed that the mischief was being done by blackbirds. However, his attention was called to a large rat taking the berries off with its mouth, and dropping them to other rats below. Presently another climbed the bush and helped to gather the berries. In a little time both came down, each with a berry in its mouth, having a curious appearance. The performance was repeated several times. Then a wire cage was placed under the bush, and in three days nine of the intruders were caught.

— CARNATION WINTER CHEER.—Of the many beautiful winter-flowering Carnations to be seen at Messrs. Veitch's nursery this appears to rank amongst the very first. For an extended period of flowering it is certainly unequalled, being now, after having been planted in the beds since the spring, in splendid flower, with abundance of buds, which will yet open providing the frost does not cut them down. In pots they are just coming into flower, and the bright scarlet blooms will during the forthcoming months amply justify the name that has been given this variety. The habit of the plant is good, being very dwarf and sturdy. There are other varieties now in flower at the above nursery, a few of the most prominent being Madame Warocque, Duke of Clarence, Mrs. Moore, and Mrs. Henry Cannell.—W.

— DEVERILL'S AILSA CRAIG ONION.—"R. M.," in the *Journal of Horticulture* of last week, correctly described the true character of this Onion up to date. When I purchased the bulbs of Mr. D. Murray of Culzean Castle Gardens, the raiser of this popular Onion, some were a very deep-fleshed flat oval, and others inclined to globe shape (I described it as such in my seed list). In the selection of my bulbs for seed purposes I have gone in for the globe shape as much as possible, and I think the stock of seed for the coming season will be very near to this type. At the same time, as "R. M." states, "both are large handsome Onions," and really I do not like to discard either type. Already I feel sure they have been doing duty for some would-be so-called new Onions, but I do not envy the practice. Mr. Murray has never favoured me with the origin of this fine Onion, only that it was a seedling of his. I was, however, quite content, knowing that I had got hold of the best exhibition Onion ever put into commerce, and I feel confident that a dozen bulbs of Ailsa Craig, weighing 26 or 30 lbs. would be more attractive to visitors at shows than 20 dozen bulbs scaling only 6 or 8 ozs. per bulb, which undoubtedly is the correct size for the kitchen. As to its keeping qualities, last year it kept better with me than any other kind (excepting the Wroxton). The rush of orders prove to me that it will be grown largely during the coming year.—H. DEVERILL.

— RHODODENDRONS AT CHELSEA.—Messrs. James Veitch & Sons, Royal Exotic Nursery, have in flower some of the most charming of the greenhouse Rhododendrons, remarkable alike for the small state in which they flower and for their extreme floriferousness. They embrace almost all colours, from the purest white to the darkest crimson. Among the most striking of those at present in bloom is Neptune (which was figured in your issue of last week), orange-scarlet, the latter greatly predominating. Aphrodite is a pale blush white, one of the most beautiful in the whole collection. Primrose, the colour of which is true to its name, has remarkably substantial flowers. Ruby is a charming variety of a rich crimson scarlet colour, and Luteum roseum has blooms tinted delicate rose on a pale yellow ground, producing a most charming shade. Jasminiflorum carminatum, which, as its name implies, is of a carmine colour, and is undoubtedly a most free flowering variety, splendid trusses being produced on every shoot, even when the plants are only 6 or 8 inches high. Maiden's Blush is one of the best, and is moreover useful, being very free. Favourite, rose coloured, is a superb flower, the truss being good and the individual blooms of much substance. Duchess of Connaught is a deep crimson, and Princess Alexandra has delicate blush white flowers, throwing large trusses most profusely. Princess Royal, pale rose; two seedlings, a pure white, and a delicate pink with a pure white tube, were also noticeable; and the same may be said of two doubles of the Balsaminæflorum section—album, pure white, and aurum, pale yellow. The trusses of the two latter are most compact, while the individual flowers are equally as large as a full-sized Balsam. These plants are eminently suitable for decorative purposes, and the blooms for bouquets or buttonholes, with which advantages they should become universally popular amongst amateurs as well as in private gardens, where it is needless to add they are already largely grown.—H. W.

— *LILIUM MARTAGON* FL.-PL.—In a recent issue of the *Journal* I mentioned this Lily, and said that I had never met with it. Much to my surprise, within a few days of the publication of the note I had a post-card from a friend in Alexandria, N.B., in whose garden I had been only a few days before, with the information that he had the double Martagon Lily. It is, as one would expect, quite hardy with him; but the flower heads when in bud are sometimes "burned" by spring frosts. The garden is close to the river Leven, and lies low, which will account for the destruction of the flowers so late in the season. In the revived taste for hardy Lilies this scarce variety will hardly be forgotten.—S. ARNOTT.

— *FOURCROYA* IN FLOWER.—A large plant of *Fourcroya* is now in flower in the conservatory of the Royal Botanic Society. The Secretary of the Society referred to it at a recent meeting of the Council. The plant is sometimes called the Century Plant, the idea being that it flowers only once in a hundred years. In reality the flower is produced only once in the life of the plant, the duration or term of life varying considerably, according to the treatment the plants individually receive. Specimens of the *Agave americana* have flowered in the Royal Botanic Society's garden, the ages of them being well authenticated as over eighty years; but the plant is known to flower in warmer climes before twenty years of age. The present specimen of *Fourcroya* is between twenty and thirty years old. It began on August 1st last to produce its flower spike, which, although the plant is slow-growing generally, developed at a rapid pace, so that on September 15th the tip had reached the glass roof. A square of glass being removed, the flower spike continued its growth, and it is now some 3 feet or 4 feet above the ridge, a total of over 30 feet in height. The leaves vary from 6 feet to 7 feet in length.

— *AGAPANTHUS UMBELLATUS*.—I can endorse the remarks (page 323) made by Mr. Parrant on the usefulness of this plant for such places as he mentions. I have a plant standing on the terrace where it was placed as soon as the spring frosts were over, and it has carried thirteen umbels of clear blue flowers, being a great contrast to the large variegated *Agaves* on each side. I have seen it employed with good effect in sub-tropical beds and remain out all the winter, but the foliage dies down and a thick covering of ashes is needed to keep frost from their crowns; but to see a plant in its real beauty it should have a place in a large conservatory, as the cutting winds damage the foliage more or less out of doors. We have two plants in pots; the flower heads have just been cut off, but the stems are still visible. One has had eighteen spikes of bloom, some carrying over 150 flowers, the average of the eighteen spikes being 123. This plant was exhibited at our local Show in July last in a class for four stove or greenhouse plants, and was specially mentioned by the press. The other is out of doors as before mentioned.—WM. SPENCER, *Errismore, Birkdale Park, Southport*.

— *MONTBRETIA CROCOSMÆFLORA*.—This is mentioned on p. 329 of the *Journal of Horticulture*. May I briefly remark (1) as to the spelling of the name *crocasmæflora*? I believe your correspondent spells it quite correctly as here, but it is not usually so spelt. The name *Crocasma* was given to a genus separated from *Tritonia* by the French botanist Planchon. Though in Nicholson's Dictionary and in most catalogues I find the name written *Crocasmia*, yet in Hooker's "*Genera Plantarum*" it is *Crocasma*, a word coined on the same model as *Coprosma* and *Diosma*. Though the only classical name I recollect of the same form *Onosma*, is of the neuter gender, the givers of the other names have exercised the privilege of making the names given by them of what gender they please, and have made them feminine; therefore *Crocasmæflora* is the correct form. (2), It is not clear whether "H. W. W." recommends these as hardy plants. When I wrote lately to M. Lemoine of Nancy, who raised the varieties and from whom I bought most of them as they came out, complaining that none of them except *Etoile de Feu* had survived the winter in the open, he replied that they were not intended to be hardy; that at Nancy none of them, not even the less tender *M. Pottsi*, ever survive the winter without the protection of a cone of straw or of dried leaves, or some such shelter over them. Gardeners in England have no doubt had varied experience of them; many I know have lost them, others protected them. One of my friends tells me that lifting in October dries the growth sufficiently, even if they are planted again directly, to make them withstand the frost of ordinary winters. The safest plan, which I shall now adopt, is to treat them, as I used in old days to treat with success *Crocasma* (*Tritonia*) *aurea*—namely, to pot them, and cover the pots with 6 inches or more of coal ashes, in any sheltered part of the garden.—C. WOLLEY DOD, *Edge Hall, Malpas*.

— *STEVENSONIA GRANDIFOLIA*.—A large specimen, probably the largest in Europe, of this rare Palm, and which has long been a feature in the Palm House at Kew, is now flowering for the first time, says the "Kew Bulletin." It is a native of the Seychelles, where it was discovered by Duncan, who sent three small plants of it to Kew in 1855, one of which was soon afterwards stolen. Probably the specimen now flowering is one of the other two, although in J. Smith's Kew Records it is stated that "four months after my retirement, in May, 1864, I learned that these two rare Palms were dead." The genus is monotypic and endemic in the Seychelles, where it grows to a height of 40 to 50 feet. The Kew specimen is 30 feet high, and has a slender, spineless stem. The leaves are cuneate, obovate, bifid, lacinated, 7 feet long and 5 feet wide, green, spotted with rusty red. The inflorescence is an erect branched panicle 3 feet long, clothed with yellow flowers. A figure of the plant has been prepared for publication in the "Botanical Magazine."

— *HARDY PLANTS AT KEW*.—The collection of hardy herbaceous plants at Kew, an exceptionally rich one, is accommodated mainly in the formal beds in the herbaceous ground and in the rockery, where collective interest rather than effect is aimed at. Many of the larger and showier species, however, require a bolder arrangement and more space than would be afforded in the herbaceous ground, and to provide this a large border, previously planted with mixed shrubs, was cleared, trenched, heavily manured, and planted in the spring with large flowered herbaceous perennials and annuals. The border, which is on the west side of the T Range, is 350 feet long and 20 feet wide, and from the end of June till the end of September it has been a great attraction to visitors. The plants grown in it are perennial Sunflowers, Dahlias, Phloxes, Hollyhocks, Gladioli, Sweet Peas, Rudbeckias, Asters, Pentstemons, Stocks, Poppies, Peonies, Foxgloves, and a large selection of other plants. Each kind is represented by a large bold mass. A few ornamental flowering shrubs, such as Roses, Spiræas, Genistas, and also a few evergreens for winter effect are mixed with the herbaceous plants—"Kew Bulletin."

— *SEEDLING POTATOES*.—The large number of new varieties of Potatoes presented for adjudication at the recent Earl's Court Exhibition proves that there is still very much of activity amongst raisers, and that the absence of ample opportunities to exhibit new Potatoes, and the comparatively low price of produce, has not materially checked enterprise on the part of those who look for some return for their labour. It is very doubtful whether any form of hybridisation or cross-fertilisation has ever been less profitable to those undertaking it than has the raising of new varieties of Potatoes. It is inevitable that out, perhaps, of fifty or a hundred seedlings, all of which must be grown, probably, two years in succession before being fairly tested, that some 60 per cent. will have to be sacrificed. After a third year's trial the remainder 60 per cent. of these go, so that the varieties are ere being put into commerce whittled down to perhaps half a dozen. Fortunate is the raiser who has so many that are really good. For exhibition purposes we, of course, want diversity in colour as well as in general appearance. Still, coloured Potatoes find a very limited demand; we want chiefly in addition to fine table quality and great productiveness, thorough distinctness, as already we have, especially of the flattish round type, a dozen varieties at least of which were the tubers mixed up it would be impossible for anyone to distinguish them. A very strong feeling was expressed at the recent Potato Show that some form of national exhibition of Potatoes should be revived. I should very much like to see that wish realised. There is ample room, but it should be conducted solely by a responsible committee, and not by one individual. I think it would be an excellent plan were a meeting of all interested in Potatoes and their culture, held on one of the days of the next Aquarium Show, and a Potato Society or Exhibition Committee might be formed that would command confidence and justify it.—A. D.

— *ARISTOLOCHIA GIGAS* AND *A. G. STURTEVANTII*.—No doubt considerable stir was created in June and July, 1841, when *Aristolochia gigas* flowered for the first time in England at the Royal Horticultural Society's Gardens, Chiswick. It had been sent home by Hartweg from Guatemala, and the first flower was produced on a small plant grown in a pot. For a long time little was heard of the Giant Birthworts, with the exception of an occasional example of *A. Goldiana*, until in the summer and autumn of 1891 a fine plant of *A. gigas* var. *Sturtevantii*, sent by Mr. E. Sturtevant of New Jersey, produced its enormous flowers in the Victoria Lily House at the Royal Gardens, Kew. This variety differs from the type in having larger flowers and much deeper colouring, as a glance at the figure in the "Botanical Register" for 1842 will readily show. The press, gardening, daily and local, noted the new

comer, and papers of the two latter classes published sensational articles concerning the size, properties, &c., of this wonderful flower, the result of which was an increased attendance of curious if not well informed visitors. Many laboured under the impression that the plant was carnivorous and had to be fed through the opening in the centre of the flower. To my personal knowledge one lady who had heard of the *Aristolochia*'s frog-eating propensity brought a poor little frog in a small card-board box, whose life was to be sacrificed to satisfy her curiosity; correct information was of no avail, and she was finally dismissed as it was past "feeding time." In the *Journal of Horticulture* for October 29th, 1891 (fig. 73) is a figure of *A. gigas*, which gives the veinings and mottlings very distinctly, but the tail seems abbreviated. The flowers are about 16 by 20 inches, with tails often almost a yard long; the centre is deep maroon, while the body of the flower is deep purple and crimson blotches and patches interveined with creamy white or pale rose. In early morning when first they open the stench is something abominable. The popular name for this fine stove climber is the 'Pelican Flower,' given in consequence of the buds resembling that bird in shape. The plants are readily propagated by cuttings, and I believe that a considerable number have been distributed through the country. Small plants occasionally flower, as was shown at Westminster on Tuesday, 20th September, when a plant in flower grown in a pot was exhibited by Messrs. F. Ross & Co. of Merstham, Surrey, and received a first-class certificate. A large plant has been flowering profusely planted out in the old Lily house (close to the Palm house) at Kew.—C. K.

THE POTATO DISEASE.

THE admirable detailed report on Messrs. Carter & Co.'s experiments, which appeared in your issue for September 22nd, was both interesting and instructive. There can be no doubt the dressing was effectual. Potatoes have been so seriously attacked in these gardens during the past three years that we were compelled reluctantly to discard some of the varieties, while in an open field some of the same sorts were good, scarcely a diseased tuber amongst them. I had decided to discard Beauty of Hebron another year. It is such a splendid Potato and such an abundant cropper that we do not like to part with it, and since Messrs. Carter's experiments have proved so satisfactory we shall retain it and dress a portion, while a part shall be left undressed next year.

Attention is wisely drawn in the report to planting the Potato a good distance apart between the rows. I have long since arrived at the conclusion that a much larger crop of tubers can be obtained from land in good heart when the rows are placed 3 feet apart than if the same ground was planted with the same kind only 2 feet apart. For years I have been in the habit of planting early varieties, such as Covent Garden, Myatt's, and others in rows 3 feet asunder to allow of early Brussels Sprouts between them. The Potatoes have grown twice as strong as those planted 1 foot less; in fact, they grow so well and crop so heavily that the Brussels Sprouts have only a poor chance unless they are very early and get ahead of the Potatoes.

One thing I particularly noticed in the report of the experiments in question, namely, that no allusion was made to the ground, or whether manure was applied for the crop or not. It would be interesting if Messrs. Carter would supply this information, and the weight of manure per acre, also if the land had been heavily manured in previous years. The condition of the land in this respect might influence largely any experiments that may be tried in the direction in which they have been so successful. I am not drawing attention to this matter for the mere purpose of criticising the report, but to elicit further knowledge on the subject, which will no doubt be freely given. I have always found that the heaviest crops are obtained from well-manured ground, but the tubers are much more seriously attacked by the dreaded murrain than those grown in fields in poorer soil. The heaviest crops of Potatoes are generally obtained in gardens, and these are frequently very heavily manured, in fact too heavily to produce tubers of the best quality free from disease. For some years I have tried to exhaust the ground before planting Potatoes upon it, by such crops of Broccoli, Brussels Sprouts, Cabbage, and Cauliflowers.

I have found on heavily manured land that has been devoted to garden crops for a number of years that a good dressing of lime before planting has been very effectual, and on the portions dressed we have had very few, and in some cases no diseased tubers.—WM. BARDNEY, *Osmaston Manor*.

[We shall be obliged if Messrs. Carter & Co. will supply the information suggested, and doubtless some of our readers will be glad if Mr. Bardney will explain the quantity of lime per rod and acre he regards as a "good dressing."]

JAPANESE CHRYSANTHEMUM, BEAUTY OF EXMOUTH.

AMONG the many new Chrysanthemums that are being constantly introduced Beauty of Exmouth, represented in the illustration (fig. 48), is destined to take a high place. This is a beautiful variety, and will probably be grown extensively, with the result of being seen in many stands next year. Beauty of Exmouth was raised from seed by Mr. W. J. Godfrey, Exmouth, and is the result of a cross between *Avalanche* and *Stanstead Surprise*, the former being the seed-bearing parent. The blooms, although large, are entirely devoid of coarseness, and are of a pure ivory white. The florets are of good substance, medium width, and curl gracefully, as shown in the sketch. The raiser informs us the plant is a sturdy grower, averaging 4 or 5 feet in height, and possesses an exceptionally good constitution. Moreover, Mr. Godfrey states that "it can be had in bloom from October to January." It will therefore be seen that Beauty of Exmouth justly merited the first-class certificate awarded to it by the National Chrysanthemum Society at the Royal Aquarium last week. It may be interesting to growers to add that *Duchess of Devonshire*, another promising variety of a rosy purple colour, also exhibited last week by Mr. Godfrey, was procured from the same batch of seedlings as Beauty of Exmouth.

[Just on going to press an extraordinary letter reaches us, containing grave allegations against one member of the Floral Committee of the N.C.S. in particular, and we may have something to say on the subject another week. The information supplied to us is of a rather startling nature, and demands serious consideration.]

WHITE CHRYSANTHEMUMS.

OUR Chrysanthemum growers are finding it very difficult to keep pace with the new varieties introduced with such abundance, especially of the white section. We seem to have got in this colour varieties so perfect that it is very difficult indeed to excel them, and yet we suppose some new ones will turn up trumps, even excelling *Avalanche* and *Stanstead White*. Now the premier coloured variety of the Japanese section last year was undoubtedly *Vivian Morel*, and it is not a matter for wonder that a white sport apparently an absolute reproduction in pure white of that fine variety, should create the liveliest interest. I do not know whether anyone else has that sport besides Mr. Wells of Earlswood, but he certainly has it in quantity. He told me that he had upwards of 1000 *Vivian Morel*, and of these he looked to find a very large number of the pure white form when they flowered. His plants shown at the Aquarium from spring root cuttings were but 18 inches in height, and carrying their very large though not fully expanded blooms.—A. D.

LARGE JAPANESE BLOOMS.

I COULD not attend the Conference held at the Royal Aquarium respecting increasing the size of the flower stands to accommodate the huge flowers now being produced in far too abundant quantities, but everyone, of course, recognises the difficulty experienced in providing broader boards and boxes. Could not the difficulty be met by putting certain recognised blooms into a big-flowered section, giving them special classes and excluding them from other classes? That would give the smaller but more refined and beautiful flowers a chance. Then to meet the case of the big blooms, let boxes that now hold twelve flowers be utilised to contain nine only, the flowers being angled, so as to give each one ample room; that would necessitate classes for nine blooms or ten blooms, taking the place of twelve and twenty-four, but, of course, only for the big ones. These huge flowers are on the whole so coarse, they evidence such lack of quality and refinement, that it hardly seems worth while to do more to encourage them than is suggested. Any flower exceeding, say, so many inches in diameter should be classed as a big bloom.—D.

PLANTS AND PROSPECTS ABOUT SHEFFIELD.

THE Chrysanthemum season now fast approaching bids fair in this district to be of the same interesting and absorbing character as it has been in previous years. For weeks preceding the great Show in the Corn Exchange the flowers that are likely to figure there are inspected, criticised, and admired by hosts of weekly pilgrims, who invade the amateurs' and cottagers' greenhouses to see their productions and note the development of the blooms. They also make comparisons with the flowers they have previously seen in a similar call upon other growers. On such days the amateur Chrysanthemum grower keeps "open house." His flowers are there to be seen and enjoyed. He does not shut himself in with a pious reserve, and keep the glory of his white, golden, bronze, and purple blooms entirely for his own pleasure, but with a wide generosity good naturedly welcomes every comer. Being such an

admirable town flower the Chrysanthemum is grown by many a humble cottager who can afford a little plot of ground and a rough greenhouse. The spirit and energy he puts into the work influences the world about him for good, enriches his own environments, opens out

in Sheffield and district are grown by amateurs who devote a large portion of their leisure time to the work. There are, however, many professional gardeners who possess facilities and have the time to produce fine blooms and plants for exhibition. There are numerous others who

FIG. 48.—JAPANESE CHRYSANTHEMUM, BEAUTY OF EXMOUTH.

the possibilities of Nature, and materially brightens unfavourable surroundings. Therefore it is creditable to a town like Sheffield that so many of its hardworking toilers have become capable in the higher cultivation of the "autumn queen." Still larger numbers every year are imitating their example, thereby widening the popular interest in its culture.

It may be said that the majority of blooms cultivated for exhibition

cultivate in good style and form, but do not exhibit publicly. A few notes on each class of growers may be of interest.

FIVE OAKS, GLOSSOP ROAD.

One of the most successful exhibitors of plants is Mr. W. Redmill, gardener to J. G. Lowood, Esq., Five Oaks, Glossop Road, Sheffield. Mr.

Redmill has set up a line of his own which previously had not been attempted in Sheffield. The group of dwarf plants he staged last year was the admiration of every visitor to the exhibition. It was an educational model of no mean order, placing as it did the Chrysanthemum in a new and interesting light of which growers with small houses might take advantage. Recently the idea was prevalent that large blooms could only be grown on plants of abnormal height; the group in question proved that splendid flowers could be obtained on dwarf plants a foot only in height which formed the front edge of his unique group, while the other specimens forming it showed how accommodating the Chrysanthemum is in regard to obtaining plants of various heights. Mr. Redmill has again this year a similar collection of dwarf plants which early in the month, after being housed, arranged, and properly staked and tied, presented a very promising appearance. Most of the plants are confined to one bloom only, which admits of smaller pots being used—a great advantage in grouping, as well as a better effect being obtained where one stem with one flower only can be fixed at discretion.

The plants are remarkably strong, with healthy, leathery, deep green foliage. The buds of many have reached a fair size, though generally he considers his plants quite a fortnight late. Among the most promising varieties are Vivand Morel, W. H. Lincoln, Criterion, E. Molyneux, Etoile de Lyon, Avalanche, Sunflower, Puritan, W. W. Coles, and Mons. Bernard. Some of the new varieties are being tried, among them being W. H. Tricker, Sunset (likely to be a very striking variety), Lizzie Cartledge, R. Ballantine (a new yellow hairy variety), J. Stanborough Dibbens, Beauty of Castlewood, George Atkinson, and others. G. C. Schwabe, Edwin Beckett, Mrs. E. Beckett, and Wm. Tunnington are receiving good attention, flowers being grown on both crown and terminal buds, to ascertain which is best. Wm. Tunnington is not yet a popular variety, but Mr. Redmill hopes to obtain a good bloom this season. A splendid bloom of Mrs. Alpheus Hardy was developing. A plant of Edwin Molyneux, carrying several incurved blooms on crown buds, was receiving treatment to retard their full development as long as possible; so also was Bouquet des Dames, an ivory white reflexed Japanese, a most beautiful early variety. These stood in a wooden shed under a north wall. The new incurved variety, Mons. R. Bahuant, has the fault of being too early. Endeavour was made to keep it back by placing it under the shade of a north wall. The leading incurved varieties are well represented by the best varieties, all of which are strong, healthy, and promising.

TAPTON HALL.

Chrysanthemums here are grown chiefly for supplying flowers for cutting, but enough are cultivated to comfortably fill two large Peach houses without detriment to the permanent occupants or undue crowding of the Chrysanthemums themselves. The plants are not massively grown, but are of medium strength, carrying three and four blooms each. Buds are fairly large, promising to give excellent blooms. They are taken both on crown and terminal shoots, according as the cultivator has determined from experience and experiment which is best for any particular variety. The plants are very creditable to the gardener, Mr. F. Hardy, and will shortly make a most attractive and interesting display, as both early and late varieties are well represented, as well as many of the best new varieties.

BIRCHLANDS.

Here, the residence of Frank Mappin, Esq., J.P., there is a large and lofty structure set apart wholly for the display of Chrysanthemums. The gardener, Mr. Farrow, is an excellent cultivator, and provides a display equal if not surpassing any in the district. His collection includes all the best of the standard varieties, both Japanese and incurved. The plants are arranged in one long, broad, rectangular bank, facing the principal door of the large conservatory. On each side of the door a square bank of dwarf plants are arranged. Very dwarf plants are not used, as in such a large arrangement they would be quite out of place. By the second or third week in November the display will be at its best, and according to present indications the flowers will be of superb excellence, the wood being very firm, the buds large and promising, and the foliage as healthy and fine as could be wished for.

AMATEURS' PLANTS.—MR. JAMES HARRISON'S, WALKLEY.

Amateurs' collections are not characterised by that neatness and taste in arrangement as are those of professionals, but they are not one whit behind in the condition of general strength and vigour of their plants. Mr. Harrison's plants are always remarkable for their extraordinary vigour. Owing to this he generally succeeds in obtaining some magnificent blooms. He has already exhibited some splendid blooms of Mdle. Lacroix and Jeanne d'Arc at a small local show. Several other varieties are developing early blooms. Criterion is well forward, while Sunflower, Belle Paule, Edwin Molyneux, and several others have exceptionally fine buds. Etoile de Lyon, which on crown buds gives coarse flowers of the wrong colour, has good buds on terminal shoots.

Mr. Harrison is not growing any new varieties this year, as he finds it more profitable to trust to the proved standard varieties which occupy leading places. However, as he becomes convinced of the merits of the newer varieties he will add them to his collection. As a practical grower he is fully aware of the stress and strain which new varieties undergo in the endeavours to propagate stock largely and quickly; and perhaps wisely, being a hard-working busy man, resolves

to wait until plants are stronger. Mr. Harrison's regard for the Chrysanthemum also extends to the early flowering kinds, numerous plants of which he has grown in the open ground, lifted and potted. The variety he favours most is White St. Crouts, a few plants also of Mrs. Cullingford, Chromatella, and several others being grown.

MR. H. BROOMHEAD.

Mr. Broomhead is a leader among amateurs, and takes a just pride in forwarding the cultivation and knowledge of the Chrysanthemum by every means in his power. His display this year will be of considerable educational value, as he possesses a large number of new varieties which it will be interesting to note. Many of them are strong, sturdy, and dwarf in habit, and when it has been ascertained which buds—crown or terminals—are best to take they will no doubt prove to be acquisitions, and take a front place in a list of varieties that do well in the district. In addition to these he has a fine representative collection of all the best standard show varieties. The plants throughout are well grown, stout, and firm in wood and foliage. The buds are prominent and well forward with the majority. One house is almost wholly occupied with varieties that either are naturally late or are grown with later buds. This will give a succession of bloom proving useful. The bulk of the plants are arranged in a large light house, which in a few weeks will be a great attraction, affording both interest and instruction to a large body of admirers and growers in and around the district.—E. D. S.

PRIZES, SCHEDULES, 1892.

WITHIN the next six weeks no less than 100 exhibitions of Chrysanthemums will be held—abundant evidence of the attractiveness and popularity of the autumn queen. It is impossible to note more than the principal prizes offered in a few of what are termed leading exhibitions, and a brief reference to some of these may be of interest to Chrysanthemum readers.

What may be termed the commencement of the regular show season begins at Gosport on the 27th October. The Society, however, does not create more than a local interest. Havant follows on the 28th with their ninth autumn Exhibition. Hitherto the prizes have all been confined to a radius, but this year many are thrown open—a step in the right direction. The shows of the last three years have brought out remarkably good cut blooms, and at no exhibition in the United Kingdom are single Chrysanthemums so well represented as here. Those who have seen this section staged in the best condition know what beauty they possess.

The Brighton Show will be held as usual in the Royal Pavilion on November 1st. The principal class is for forty-eight cut blooms, the first prize being £10. On the following day several important fixtures take place. Ascot, for instance, at which, perhaps, the best groups of Chrysanthemums are to be seen. Another special feature of this Society is the extent and high quality of the cut blooms in the reflexed section, special encouragement being given to this class.

The Portsmouth meeting is fixed for the same day as usual (November 2nd). This Society is the pioneer of cheap admission with a view to encourage the lower class to take an interest in floriculture, and especially the Chrysanthemum. The Show itself has for some years been looked upon as the best south of London, and equal to any, even in the metropolis, and certainly much superior to many in northern towns. This year £10, £7, £5, £3, and £1 10s. are offered for forty-eight cut blooms, instead of a challenge cup or vase as in the past. The conditions of entry are easy, only eighteen varieties being required in the incurved and Japanese sections, the blooms to be half of each. £5, £3, £2, and £1 are also offered for twenty-four distinct varieties, half to be incurved and the remainder Japanese, which prizes ought to bring the finest exhibits possible. There are no less than thirty classes altogether devoted to cut blooms in addition to several for epergne and other forms of decoration. Good prizes are also given for groups. The end of the same week will see the usual brilliant gathering at the Crystal Palace, Sydenham, which is really the commencement of the London programme. At no Exhibition is the competition so brisk as here, except perhaps at Birmingham.

The following week is perhaps the most busy of all. On Tuesday 8th the "National" holds its annual meeting at the Royal Aquarium, and Kingston as usual in the Drill Hall. At the former, in addition to the competition open to societies only for forty-eight blooms, the premier award being the usual trophy and £10, the Holmes Memorial challenge cups with money prizes of £10, £7, and £4 are offered in separate classes for incurved and Japanese blooms, thirty-six in the former and forty-eight in the latter, all to be distinct. These two are the most gigantic classes ever offered in the matter of varieties, and will put to the test the fullest capacity of any grower, private or otherwise. None but the largest cultivators can expect to compete, therefore the entry cannot be a large one. An opportunity is here given for the inclusion of some of the smaller kinds of incurved blooms which are now seldom seen. Although the Japanese section is a wide one forty-eight distinct and meritorious blooms will require some staging by one person. A splendid opportunity is afforded of testing the suggested increase in the size of the stands for Japanese blooms as there are no restrictions in this respect. Space forbids me saying anything about the remaining thirty-seven classes for cut blooms only, which affords ample opportunity for all classes of competitors.

At Kingston there is the usual challenge vase with £5 added as first prize for forty-eight distinct blooms—a thorough test of the cultural skill

of anyone. Mr. Carpenter was successful last year, and will no doubt do his best to retain the honour, although I hear he will have to look to his laurels. Numerous other valuable prizes are offered, sufficient to make a most attractive exhibition in themselves.

Birmingham, long recognised as the Chrysanthemum centre of the Midlands, hold its Show on the 8th also, making the thirty-second exhibition held in this busy town. This Society has obtained the credit of being the initiator of large prizes for cut blooms, and also obtained the record in the number of competitors, no less than eighteen competing in the class for forty-eight blooms in the year 1890. This year a proposition was carried, by a bare majority of the Committee, to divide the large class. For this change it is difficult to assign a reason after the brilliant successes of the past. The classes now are twenty-four incurved, distinct, for which six prizes are offered, ranging from £10 down to £1, a similar class being also arranged for Japanese. Time alone will prove the wisdom or otherwise of this step. Prizes of £10, £7, £5, £3 are also offered here for a group of Chrysanthemums, which will no doubt bring out good results, as in the past.

Bristol inaugurates its twenty-ninth season on the 16th in the Colston Hall. This Society has long been recognised as the leading one in the West of England. For some reason or other the Committee have dropped their large prize, being content with offering one of £5 for twenty-four incurved in not less than eighteen varieties. Beside this there are numerous other smaller classes, quite sufficient to provide a display equal to any of the past.

Liverpool, I ought to have previously mentioned, holds its Show on the 15th as usual in St. George's Hall. This has for a number of years been regarded as the pioneer of northern exhibitions. Perhaps nowhere is the competition so keen throughout as here. The neighbourhood abounds with gentlemen who almost to a man encourage the growth of Chrysanthemums. There is one blemish which I cannot but point out—the indifferent manner in which the small-flowered sections, such as Pompons, Anemone Pompons, singles, and even Anemone varieties are cultivated and exhibited at this centre.

On the following day York and Hull commence their shows, both being well supported by exhibitors and public alike. The latter perhaps is the more important of the two, offering as they do greater inducements to exhibitors. This Society can justly lay claim to offering the largest prizes for cut blooms this year. No less a sum than £10, in addition to a silver cup, heads the prize list for twenty-four incurved. The class is made easier also for exhibitors through its not being distinct. Duplicates are allowed in six blooms. The Japanese blooms are provided for in a similar manner as regards the amount of prizes, the only difference is that they must be distinct—a reasonable clause in this case. Numerous small classes are also provided for open competition. The same remark applies to amateurs also, and to those who reside within a given radius. This Society is also noteworthy for offering the largest prizes for a group of Chrysanthemums interspersed with foliage plants. No less a sum than £6 is offered in addition to the 20-guinea challenge cup offered by G. Bohn, Esq., as the first prize. It is not too much to say that this Society has the best exhibits of this kind of any Society in existence. Those persons who admire skilful arrangement of flowering and foliage plants combined during the dull month of November should go to the Artillery Barracks in Hull, and if they are not impervious in this respect they will not regret the journey, be it long or short.

Edinburgh follows the next day to Hull, the site, as usual, being the Waverley Market, which has no equal in the kingdom for such a display. No society that I know has made such rapid progress in the quality and quantity of the exhibits in such a short space as this—the Scottish Horticultural Association. Offering most liberal prizes, the management have ample grounds for such an undertaking, and being practical men there is no wonder at the progress made on the other side of the border. True, the standard in the incurved flowers falls below that usually seen in England, the bulk of their strength lying in the quality of the Japanese blooms.—E. MOLYNEUX.

NATIONAL CHRYSANTHEMUM SOCIETY.

CONFERENCE AT THE ROYAL AQUARIUM—OCTOBER 12TH.

As briefly announced in our last issue, a conference was held, under the auspices of the National Chrysanthemum Society, at the Royal Aquarium, Westminster, on the above date, to consider the advisability of increasing the size of show-boards for exhibiting Japanese blooms. Sir Edwin Saunders, the President of the Society, occupied the chair, and he was supported by Mr. R. Falconer Jameson (who had come especially from Hull for the purpose of attending the conference), Mr. R. Ballentine, and Mr. R. Dean, the Secretary. About one hundred members were present, amongst them being many of the leading Chrysanthemum growers.

After a few introductory remarks from the Chairman, Mr. Dean proceeded to read a number of letters which he had received from affiliated societies, in response to a circular asking for opinions as to the proposed alterations. The majority of these thought that an increase of size was necessary, whilst a few considered the existing boards large enough. Mr. Rundle, however, who represented the Leicester Chrysanthemum Society, said that the committee of the latter organisation thought an alteration most desirable, the boards for various numbers of blooms being made proportionately larger than those now in general use. A paper by Mr. C. E. Shea (who, being in Italy, was unable to be present) was then read by Mr. R. Dean, following which came essays by Mr. R.

Falconer Jameson and Mr. Herbert Fowler. The papers, which pressure on our space compels us to slightly abridge, are given below.

SHOW-BOARDS FOR JAPANESE CHRYSANTHEMUMS.

BY MR. CHARLES E. SHEA.

For some seasons past there has been evidence of the existence, on the part of many exhibitors, of a growing feeling of dissatisfaction with the present regulations concerning the show-boards required, or permitted (as the case may be), to be used for the exhibition of Japanese Chrysanthemums. Hence it has been decided, and I think wisely, to take advantage of the present October show to invite a full and free discussion of the subject, with the result, it is to be hoped, that a sufficient expression of opinion on the one side and the other will be obtained, so that the real wishes of the general body of exhibitors may be made apparent for the information and guidance of the Society.

It is obvious that the onus of establishing an affirmative case calling for alteration of the existing practice rests with those who assail it, and it must be remembered that inasmuch as the rules of the National Chrysanthemum Society, and of many other societies also, already permit the exhibitor of Japanese Chrysanthemums to stage his blooms on boards of any size, the case so to be made out must necessarily include the principle of compulsion, as well as proof that the existing regulation boards, with the 6-inch space between the blooms (centre to centre) are insufficient for the requirements of modern showing—at least, so far as the Japanese section is concerned.

For the sake of indicating the lines which the discussion must necessarily take, I would say that we who accept this *onus probandi* must be prepared to prove:—

1, That uniformity of method of exhibition is so essential, or at least desirable, that compulsion upon the subject ought to prevail.

2, That (the necessity for compulsion established) the existing regulation stand is insufficient for the adequate display of the Japanese Chrysanthemum, and that the necessity for an alteration outweighs the objections which may be urged against it. Then

Lastly, The dimensions of the new board which shall be accepted as the regulation show-board of the National Chrysanthemum Society and its affiliated societies, and doubtless, of most if not all, of the leading Chrysanthemum Societies throughout the country.

We have thus the map, or plan, of the discussion before us. Let us at once deal with point No. 1, compulsion, compulsory uniformity.

One argument in favour of enforced uniformity at once presents itself, that of analogy. We have but to look at the methods of exhibition of other flowers, notably of the great sister-queen—the Rose—to see that uniformity of staging is held to be an essential of fair competition. And I think that it requires but little consideration to recognise that this view is the correct one. The object of competitive exhibition is to test the comparative excellence of rival blooms, and it is obvious that it must tend to render this test more effectual if the conditions under which the several blooms are presented to the eye of the judge are as nearly as possible identical. In all scientific analyses and comparative examination all matters tending to create varying conditions are carefully eliminated, and why should it be otherwise with the judgment of the comparative excellence of flowers? It is a matter of common knowledge that the eye is very easily deceived as to the relative dimensions of two bodies of the same size but presented to the eye under different conditions, and some very ingenious devices, having this scientific fact for their basis, have been utilised as advertisements for Pears' soap. So it is a fact beyond question that if the blooms of one exhibitor are staged on a stand with 6 inch, and another with 7 inch or 8 inch spaces, the eye of the judge will, in greater or less degree, be misled. And there is no room for such misleading when the results of twelve months of patient and skilful care are submitted for judgment, and the reputation of the exhibitor is at stake. So long as the size of the show-board is merely a matter of option a prudent exhibitor will hesitate to adopt a larger stand for his own exhibit while his opponent is using a board which gives to the blooms a relatively larger apparent size, and, by crowding them together, gives to a weak and shallow bloom the appearance of a solidity which it does not possess. All the surroundings of competitive exhibition ought, as far as possible, to be uniform, and it is, in my judgment, a fit matter for compulsion that, as with Roses so with Chrysanthemums, blooms should be staged by exhibitors upon stands of similar dimensions.

We now reach the second point. Are the present show-boards, with the 6-inch spaces, sufficient for the effective exhibition of the Japanese Chrysanthemums of the present day? At first sight the reflection naturally presents itself, that, inasmuch as the present boards were devised very many years ago when the blooms were not nearly of the dimensions now attained, either those who were then responsible for the selection of the dimensions were very much at sea upon the subject, or the dimensions then fixed must necessarily be entirely insufficient for present day requirements. It is difficult to avoid one or other of these alternatives. But, passing from mere inference to the evidence of our own personal experience, can we fairly say that the Japanese blooms of the present day can be satisfactorily judged when staged upon the present boards? My own opinion and experience is that it is not possible. It is, with certain obvious exceptions, doubtless substantially true, as stated by Mr. Norman Davis, that the present increase in dimensions of the blooms "is not so much in size (diameter I presume is meant), but in the depth and solidity of the blooms." And it is just these important aspects of depth and solidity which it is impossible for the judges to accurately estimate when the blooms are so crowded that

they touch each other. It is true, as Mr. Davis also says, that only two blooms on a 12-board touch each other at all four points, but six more touch at three points, while the corner blooms touch at two. This alone is quite sufficient to impede satisfactory judging. It must be remembered that judges rarely have more time, generally less, than they require for the proper discharge of their functions, and it is impossible for many reasons that they should lift every bloom from the "general conglomerate mass of interlacing petals," which is almost the correct way of describing a modern show-stand in the smaller classes. Everything ought to be so arranged that the judges can, with the least expenditure of time and trouble, satisfy themselves as to how far each individual flower realises, or falls short of, those essentials of diameter, depth, and solidity which go to make up the perfect show bloom. And this becomes the more important in face of the growing demand that, in all close and important competitions, each individual bloom should be "pointed up."

That a striking consensus of opinion on the part of a large number of the leading exhibitors, to the effect that the present regulation show-board is insufficient for the proper exhibition of such giants as *Etoile de Lyon* and its white sport *Lillian Cope*, *Vivian Morel*, *E. Molyneux*, *et hoc genus omne*, was brought to light by Mr. R. Falconer Jameson's circular letter, few will be disposed to deny. But the argument has been brought forward by the worthy Vice-Chairman of the Committee of the National Chrysanthemum Society, that to enforce the use of larger boards would be "practically legislating for the few at the expense of the many." And he proceeds, that "whilst it is perfectly true that a few of our most successful exhibitors find the regulation boards too small, it is an undoubted fact that they are quite large enough for an overwhelming majority of those who show Japanese blooms." Now, I think that it might be replied that even were it conceded that the existing board is large enough for the majority of those who merely show Japanese Chrysanthemums, that fact is entirely beside the practical question, if it be also the fact—and I think it is—that the board is not large enough for those who take the prizes. In other words, the question at issue practically concerns, and only concerns, those who, with more or less regularity, make their appearance in the prize lists. For the larger number who, throughout the country, show, but never, or rarely, take prizes, and who go to make up Mr. Jukes' "overwhelming majority," are, I would submit, unaffected in any real sense by the change which it is proposed to make; nor can it be fairly said that it would be at their expense.

It may be true, as Mr. Jukes puts it, that "small blooms on a board too large for them are much less effective than massive blooms on a small board," and that the former condition of affairs is calculated to "spoil the effect of the exhibit." But we must remember that the substantial object in view is not the "effect of the exhibit" of those who have no chance at all of taking a prize, but the satisfaction of the requirements of those between whom the issue of first, second, and third prize must rest. The exhibitor who in no event can hope for a prize in the class in which he competes can scarcely ask that facilities for accurate judgment of the leading stands shall be withheld simply because their adoption would damage the "effect" of his own exhibit. Considerations of mere sentiment must give way to those of practical utility. And, I would ask, Does it accord with our experience that "only a few of our most successful exhibitors find the regulation boards too small?" The quality of the exhibits of many, if not most, of those who figure in the prize lists at the chief shows throughout the country is fairly well known to me, and I must say that I think that in nearly every case a larger board would have more adequately displayed their exhibits. To my mind, the necessity for some enlargement of the existing regulation board in the interest of a sufficiently large proportion of the successfully competing exhibitors throughout the country has been demonstrated, and I would now pass to a consideration of possible objections to a change on other grounds.

First we have that of expense. That some expense will attend the change is undoubted, but that objection, real and reasonable as it is, within certain limits, must not prevail to arrest a needed reform. We must not spoil showing altogether because of the expense of rendering that showing satisfactory and effective. Boards and boxes wear out, and whether a "period of option" for a season or two, leading to an after period of "compulsory uniformity" might be conceded to meet this point, might perhaps be a matter for the Committee of the National Chrysanthemum Society; but unless the objection be found to be very pressing it would certainly be desirable to give immediate effect to any change which may be decided on. Portability is a real objection so far as it goes; but, again, not of sufficient weight, *per se*, to be set off against the major consideration of a proper exhibition of the flowers. The substantial end cannot be sacrificed to mere consideration of detail. Besides a reasonable and probably sufficient measure of reform may not, after all, so greatly affect the question of portability as some assume. Next, a greater inroad on the space available at the places of exhibition. A substantial objection, but one which it seems to me must be met rather by a limitation of the number of classes where absolutely necessary, than by the sacrifice of the quality of the judging all through the show, for it amounts to that if it be once conceded that the increase in the size of the show-boards is necessary. And besides the small increase which may be found necessary, and that perhaps in Japanese only, would, on the assumption that the Japanese exhibited are equal in number to all the other sections taken together, only mean some 3 inches to a yard of space on the stage. Not so very much after all.

A last objection—"Mixed classes" would look very awkward. Some think not, but that the irregularity which already exists where incurved

are shown side by side with Japanese Chrysanthemums would be scarcely noticeably increased by a slight addition made to the size of the Japanese board. Others are of opinion that if the suggested alteration should lead to the abolition of "mixed classes" altogether so much the better. An opinion which, I must confess, I am inclined to share. Reviewing the various objections which have been urged against an enlargement of the regulation board I think that the conclusion must be, that although some of them have a measure of weight they altogether fail to supply a sufficient reason for withholding the reform which is called for. What then shall be the dimensions of our new regulation Japanese show-board? Looking at the necessity for some enlargement, and giving all due weight to the objections which I have enumerated, I should say that an increase of 1 inch—namely, from 6 to 7 inches between the holes, centre to centre—would reasonably satisfy the requirements of the case. Whether it would be necessary to have a margin, back and front, of full $3\frac{1}{2}$ inches is a moot question. Those who have boxes rather larger than their stands would find 3 inches sufficient, and less space would be taken on the show table. But this is a detail merely.

Some restriction of the system of allowing duplicates would also tend to keep the "giants" in their places, and allow that relief to the space which is afforded by the smaller varieties; and a regulation limiting the diameter of the cup, or disc of card or wire, by which the blooms are extended beyond the position of natural growth, would also help matters. It is, of course, possible that were there no such counter-vailing considerations as those which I have noticed, even a larger increase than I have suggested might be found desirable; but in this matter compromise must come in, and the spirit of moderation should direct our counsels. We shall doubtless hear the opinions of many practical exhibitors, and to the united wisdom and experience of the meeting we can safely leave the decision of the exact size of the future board, but this I would suggest: let that size be settled upon some definite principle, and do not let the point depend upon the average of a number of different suggestions; otherwise reasonable proposals may be altogether negated and swamped by someone's altogether preposterous suggestion—like the 40-inch by 30-inch board for twelve blooms, as proposed by one of his correspondents in answer to the circular of Mr. Falconer Jameson. I am confident that, whatever be the result of the conference, its decision will be heartily endorsed and loyally observed by all true lovers of the Chrysanthemum.

STANDS FOR EXHIBITING JAPANESE BLOOMS.

BY MR. R. FALCONER JAMESON.

IN connection with the question of size of stands for exhibiting Japanese blooms, there are two main points to consider: First, whether it is desirable to increase the present standard size? Secondly, if the first question be answered in the affirmative, how much should the size be increased? I take it for granted that the general feeling would be almost unanimously in favour of the size being enlarged but for the expense which would be entailed upon exhibitors. The Executive of the National Chrysanthemum Society have themselves, for a long time past, admitted that an enlargement is desirable by allowing Japs to be shown on boards of any size. In this I think they have made a great mistake. Had they, instead of allowing boards of any size, stipulated for an alternative size specified by them, the change would have been, to a great extent, effected ere now and without any burden having been cast upon exhibitors.

Who will be so bold as to assert that Japs show to better advantage crushed up one against another, or overlapping one another, than if standing just clear all round? There is beauty of form to be considered as well as beauty of colour, and the former essential is lost when the flowers are crushed out of shape. How, I ask, would incurved blooms look if jammed up one against another? and what applies to incurves applies also to Japs. Does any gardener, in planting shrubs, arrange them overlapping one another? I trow not; he allows a clear space round each one, and if in course of time they increase in size to such an extent as to mar their beauty, he then thins them out.

Personally I deprecate any sudden compulsory change being made, but I suggest, as I have already done in the press, that the National Chrysanthemum Society should, for the present, allow exhibitors the option of using one of two sizes, either the present standard size, or a larger one about to be specified. I feel convinced that if this were done the good sense of exhibitors would lead them to gradually change to the larger size, which, in course of a short time, might be made compulsory without putting exhibitors to great expense. Some will argue that two sizes of boards would destroy uniformity on the show tables, but they must not forget that as at present any size is allowed there is chaos rather than uniformity.

I will now pass to the question of what size should be substituted for the present one. In January last I published the result of replies received in response to a letter I had addressed to some of the leading growers asking their opinions. Out of the thirty-eight replies I received, only two were in favour of the present size being retained, the others voting as follows: One 27 inches by 18 inches, one 27 inches by 20 inches, one 27 inches by 21 inches, two 28 inches by 20 inches, eight 28 inches by 21 inches, six 28 inches by 22 inches, one 30 inches by 21 inches, one 30 inches by 22 inches, one 30 inches by $22\frac{1}{2}$ inches, two 30 inches by 24 inches, one 31 inches by 21 inches, four 32 inches by 24 inches, and two still larger. Of the remainder some do not specify dimensions, while others made various suggestions. It will thus be seen that more are in favour of 28 inches by 21 inches than of any other size,

and this allows 7 inches per bloom in each direction, being 1 inch more than at present. It seems to me very desirable to allow the same space for the blooms in each direction.

ON THE SIZE OF BOARDS.

BY MR. W. HERBERT FOWLER.

THE subject seems to me to divide itself into three heads:—(1) Is any change necessary? (2) If necessary, how large should the new boards be? (3) The best way of carrying out the change.

In considering the first point we have several things which may aid us in coming to a decision. I think few will deny the fact that a large number of the public who come to the shows are asking for a move in the direction of larger boards and more room for the blooms, thus giving them a better chance than at present for critical examination. Then we have the judges to consider. Is it possible for them at present to see anything but a part of the flowers without taking them out of the stands for examination? The enthusiastic grower will surely welcome a change, so that all his flowers will be seen, instead of the front row and the tops of the middle and back rows.

I think that for forty-eight or even thirty-six distinct Japs, the present boards would perhaps carry the blooms without doing them any great injustice, but for all the smaller classes—viz., the sixes, twelves, eighteens, and twenty-fours, I am strongly of opinion that the present size is quite inadequate to carry the large varieties which are now grown. I daresay some will meet this movement with the argument that the present regulations allow of any size board being used for Japanese blooms, and why, therefore, make any compulsory change? I think the answer to this is simply this. If an exhibitor uses a larger board than the ordinary one he at once places himself at a great disadvantage with others who use the regulation one, because his stand if at all equal with the others will appear to be much lighter. The general effect of a crowded stand is to give weight to the stand and *vice versa*—e.g., take twelve blooms and stage them on the regulation board, and then take them out and try a board 6½ inches between the tubes, and you will be surprised to see how much lighter the same blooms appear to be.

Another reason I should give in favour of enlarging the boards is that I think it would induce exhibitors to abstain from using extra wires and endeavouring as far as possible to make all the blooms touch each other. If more space be given it would be more difficult to spread out blooms in an unnatural way in order to get a false appearance of "weight." Such practices would then be much easier to detect. Whilst I am in favour of an enlarged board I am strongly of opinion that whatever the sized board agreed upon may be should be the one used at all exhibitions of the Society for Japanese blooms. The regulation which permits exhibitors to use any sized board for Japanese blooms should be withdrawn and one standard size fixed. This will put all exhibitors on the same footing, and greatly assist the judges in their work. Although I am strongly in favour of an enlarged board, I am against going too far and attempting to introduce a monster board which would have a poor chance of being taken up and becoming popular with exhibitors. I have made several experiments, and in 1890 I adopted 26 inches by 19½ inches as the size of my twelve-bloom boards; this allows 6½ inches from centre to centre of each tube. If, however, the majority think that it should be larger than this I do sincerely trust they will not go beyond 7 inches—viz., 28 inches by 21 inches for the twelve board. It will, I think, be found by experiment that a board 27 inches by 19½ inches will carry even the small classes without doing injustice to the flowers. Another reason against making the boards too large is that it would involve a serious addition to the space necessary to stage a large number of flowers; and again, it would work very badly in the mixed classes if one had to stage the Japs on one sized board and the incurved on another. I trust we shall soon see an end of these classes, as they are in all respects unsatisfactory.

Now we come to the third point, "The best means of carrying out the alteration." I think that the ordinary box is a complete mistake, and I would advise all beginners and those whose old boxes are worn out to adopt the travelling box instead. By this I mean a box with fixed tubes in it, in which the tubes holding the blooms are dropped. The stands for setting up the blooms are carried separately, and the blooms transferred to them on arrival at the show. There are many advantages in this plan. In the first place you can give much more room to each bloom, then you need not fear the effect of a leaky tube, there is no risk of a leg of a stand getting loose and coming down and cutting a bloom in half, and the side blooms will not suffer against the box in a long railway journey, as they often do with the old-fashioned box.

DISCUSSION.

AN interesting discussion followed. Mr. WILLIAM DROVER, Fareham, showed an exhibition board which he had made, and which was of the following dimensions:—28 inches by 21 inches, 3 inches in the front and 8 inches at the back in height, and 7 inches from the centre of each hole. Mr. Drover said that when he was first asked about the size that should be adopted for exhibition boards for Japanese blooms, he was of opinion that the usual sized board would do; but, on further consideration, he thought that a larger stand would be advisable.

Mr. W. H. FOWLER proposed, "That the size of the boards for Japanese blooms for the future be 27 inches by 19½ inches, and that all Japanese blooms be for the future exhibited on such size stands only." Mr. WHITTLE seconded the proposition.

Mr. C. GIBSON moved as an amendment: "That the size of the

boards for Japanese blooms be that recommended by Mr. Drover—viz., 28 inches by 21 inches, 3 inches in front and 8 inches at the back in height, and 7 inches from the centre of each hole." He thought that this size was not at all too large. The blooms would be larger at next month's shows, and a board of the size proposed by Mr. Drover would enable the public to see the beauty of the blooms and also render the task of the judges easier. Mr. H. CANNELL seconded the amendment.

Mr. BALLANTINE, in supporting the amendment, thought it best to go the full length rather than have any half measures. It has been very clearly proved that some change is necessary. The time has come, he said, when exhibitors should change the size of the board, and it would be the better plan to adopt a size which will meet the wants of the future as well as of to-day. Mr. Fowler's board (27 by 19½) would do for the blooms we now have; but if we made the size 28 inches by 21 inches it would meet all the wants of the present day. He had pleasure in supporting the amendment proposed, that the size of board for Japanese blooms should be 28 inches by 21 inches, and that that limit should be compulsory.

Mr. MOORMAN supported the amendment, but observed that there was nothing new in the size board proposed by Mr. Drover. It had been used in 1879 at Southampton, in 1882 and 1883 in the Royal Aquarium, and at Kingston and other places.

Mr. RICHINGS also spoke in favour of the amendment. He said that as at present staged it was impossible to see the full beauty of the blooms or to discover any defects. In fairness, therefore, to the exhibitors and to the public it was most essential that each bloom should stand out on its own merits, and that the judges should be able to see each bloom. He had not heard one argument advanced why the size of the boards should not be increased.

Mr. ROWBOTTOM referred to the desirability of increasing the height of the present board at the back.

Mr. FOWLER thought that the height should be left to the exhibitor. At the present time the board used was only 6 inches in height at the back. As they were not allowed to put the boards higher they put the blooms higher instead.

Mr. FALCONER JAMESON observed that exhibitors might avoid a great deal of the expense which would be caused by a change in the standard size of boxes by using their old trays and boxes for carrying the flowers to and from the shows.

Mr. D. B. CRANE was in favour of the board proposed by Mr. Fowler. He thought it would meet all the requirements of blooms that are exhibited at the present day. He considered that it was most essential that there should be a regular sized board, and in the arrangement of the blooms on the board he was in favour of uniformity.

Mr. H. J. JONES referred to the importance of considering the distance that should be decided on between the holes in the boards. He was in favour of fixing this distance at 7 inches from centre to centre.

Mr. HARMAN PAYNE spoke in the interests of amateurs, cottage growers, and persons of that class, contending that as they are quite unable to produce very large blooms, if a larger exhibition board is insisted on, their somewhat smaller flowers will look rather absurd on such boards. He thought it would be well to add a clause or condition that in the amateur and cottagers' classes the larger board should not be compulsory. The ordinary amateur grower would not, he thought, be able to fill the new board.

Mr. BALLANTINE explained that the whole question would have to go before the General Committee of the Society—the Committee being bound to form its own rules.

The amendment in favour of Mr. Drover's sized board was then put to the meeting and carried by about 38 to 7.

A hearty vote of thanks to the Chairman and to each of the readers of the papers closed the proceedings.

ROYAL HORTICULTURAL SOCIETY.

OCTOBER 18TH.

CONSIDERING the time of year there was an excellent display at the Drill Hall, Westminster, on the above date. Orchids were not particularly numerous, but cut flowers and foliage plants were well shown. As regards fruit it is seldom that such a fine display can be seen on these occasions.

FRUIT COMMITTEE.—Present: P. Crowley, Esq. (in the chair); with Rev. W. Wilks, Dr. Hogg, Messrs. John Lee, T. F. Rivers, W. Warren, T. J. Saltmarsh, J. Willard, H. Balderson, J. Hudson, G. Wythes, G. Sage, A. H. Pearson, G. Taber, A. Dean, Harrison Weir, and J. Wright.

There was a splendid display of fruit in the hall, such as not many years ago would have been thought impossible, and justice could only be done to the collections by awarding several valuable medals. These collections half filled the building.

The first products placed on the Committee table were from Messrs. Cooper, Taber, & Co., Witham, Essex. A new American Golden Melon, ovate and smaller than the Queen Anne's Pocket Melon, though not so good; the Vegetable Peach Melon, also small, but round and better. The season was really too late for these miniatures. Messrs. Cooper, Taber & Co. also sent fruits of the Japanese Pole Cucumber, so called because the plants are said to be supported by poles; it is of the ridge character, and said to be very free; also very fine samples of Worcester Pearmain Apples (vote of thanks).

Messrs. Dicksons & Co., Edinburgh, sent a dish of James Grieve

Apple, a medium-sized conical Apple, with soft flesh, but no award was made. Mr. J. Bowerman, Hackwood Park, Basingstoke, sent highly coloured fruits of a seedling Apple resembling Red Astrachan, but keeps till Christmas (passed). Mr. W. Longley, The Mall, Mersey, Faversham, sent a dish of a seedling Apple, which was determined to be Golden Noble. Mr. Robert Morrow, Leominster, exhibited a seedling Apple, named Hampton Court Pippin (passed). Mrs. Taylor, Twickenham Road, Isleworth, sent a seedling Apple from Golden Noble (passed). Mr. F. Smith, Loddington, sent a seedling Apple having some resemblance to the American Mother, but not nearly so good, and was passed. Mr. W. Bull, Ramsden, sent a seedling Apple, somewhat like the Nonesuch, but not so good, and no award was made. It is to be hoped that not half the seedling Apples that are raised will be propagated for distribution. The country is already too full of mediocrities.

Mr. G. Wythes sent a seedling Melon, fruit round, yellow, smooth, scarlet, flesh sweet, and considered one of the best of the season. It was named *Beauty of Syon*, and was awarded a first-class certificate. Mr. A. Bishop, Westley Hall Gardens, Bury St. Edmunds, sent a fine looking Melon, but a week or more too old, and decay had distinctly set in. Mr. W. C. Leach, Albury Park, sent splendid clusters of his *Lady Bird Tomato*. Fruits of full size, very heavy, rich in colour, and of good quality. The bountiful way in which the fruits are produced should render Lady Bird a Tomato for the million (first-class certificate). Dr. Hogg sent fruiting branches of Catawissa Raspberry, perhaps the best autumn bearer, also highly coloured fruits of Cox's Orange Pippin and Cellini, grown on the Hastings sand (vote of thanks).

Mr. Willard sent specimens of the silver or Seakale Beet, to draw attention to its usefulness for culinary purposes. As dressed they resembled heads of Celery (vote of thanks).

Mr. Barron brought from Chiswick bunches of an Hungarian Grape, Oreg Tirardovanny—a Chasselas Grape of extraordinary juiciness, a refreshing white Grape for invalids. Also the Muscat of Hungary, a miniature Muscat of delicious quality. Mr. Rivers brought a box of the Guigne de Winckler, a Cherry of German origin, and useful because of its late ripening character. He also sent fruits of the Purple Crab, round small crimson, ornamental, and fairly good eating (vote of thanks).

Messrs. Jarman & Co. sent some splendid Onions, comprising Prize-winner, Somerset Hero, International, and others (cultural commendation).

Mr. G. Wythes, Syon House Gardens, contributed a very extensive collection of Apples and Pears. Cellini, Lady Henniker, Alfriston, Norfolk Beefing, Dutch Codlin, and Pitmaston Duchess were very fine (silver Knightian medal). Mr. Mortimer, Rowledge, Farnham, contributed nine boxes of Apples, of which Warner's King and Golden Noble were good examples, and a collection of Grapes (silver Banksian medal). Mr. Blick, gardener to Martin Smith, Esq., exhibited twelve dishes of very fine Pears, Marie Louise, Princess, Magnate, Doyenné du Comice, Marie Louise d'Uccle, and Pitmaston Duchess were splendid, and Uvedale's St. Germain very large indeed (silver Banksian medal). Mr. Molyneux, gardener to W. H. Myers, Esq., M.P., Swanmore, sent dishes of Mère de Ménage and Cox's Orange Pippin Apples to show the colour, of which they were certainly very full. Mère de Ménage was heavily burnished. He also sent splendid fruit of Warner's King from trees planted in 1890 (cultural commendation). Mr. Becker, Jersey, sent dishes of four new varieties of Apples, named Jersey Lily, Yellow Admirable, Royal Jersey Pippin, and Monstrous Incomparable. For the latter, very large and symmetrical, an award of merit was recorded. Mr. Balderson exhibited a small collection of Grapes. Mr. Nicholson, gardener to J. W. Meller, Esq., Chingford, sent a good collection of Pears, and was awarded a bronze Banksian medal.

Messrs. Paul & Son, The Old Nurseries, Cheshunt, contributed a splendid collection of Apples in dishes and baskets. Golden Noble, Frogmore Prolific, Counsellor, Mère de Ménage, Beauty of Kent, Cheshunt Pippin, Lane's Prince Albert, Lord Derby, Transparent de Croncelles, Warner's King, Magnum Bonum, Cox's Pomona, Betty Geeson, Mabbot's Pearmain, and Loddington's Seedling were finely shown, some being very full of colour (silver Knightian medal).

Messrs. J. Peed & Sons, Streatham, contributed a large collection of Apples and Pears, Dutch Codlin, Lord Suffield, Annie Elizabeth, Warner's King, Small's Admirable, Cellini, Peasgood's Nonesuch, Rymer, Beauty of Kent, and Cox's Pomona being the most noticeable (silver Banksian medal).

Messrs. J. Veitch & Sons had a collection covering one side of a long line of tabling, and admirably displayed. Warner's King, Sandringham, Baumann's Reinette, Stirling Castle, Seaton House, Winter Hawthornden, Barker's Seedling, Lane's Prince Albert, Bismarck, Lord Suffield, Peasgood's Nonesuch, Stone's Apple, Lady Henniker, Tom Putt, Alfriston, Mrs. Barron, Manks's Codlin, and The Queen were very fine indeed (silver-gilt Knightian medal).

Messrs. J. Laing & Son had many dishes of well-coloured fruit, amongst which Cellini, Alfriston, Lord Derby, Peasgood's Nonesuch, Mère de Ménage, Bismarck, Golden Noble, and Washington were remarkable both for size and colour (silver Banksian medal).

FRUIT DRYING AT CHISWICK.

Several examples of fruits that had been dried at Chiswick by the Mayfarth apparatus were exhibited both as rings and chips, also cooked for use, with the same varieties of Apples cooked in a fresh state. The dried produce, whether boiled or baked, was quite equal to the fresh in quality and had lost nothing but water in drying, and this was absorbed

by immersing the Apple chips, &c., for two hours and the Plums and Damsons for six hours. The Apples tested as described were Cellini, New Hawthornden, Blenheim Orange, and Beauty of Hants. The following is Mr. Barron's report of the experiments:—

FRUIT DRYING.

During the operation a temperature from 175° to 200° is required for Apples, and the time occupied is about three hours.

10 lbs. of fresh fruit of Cellini	give 1 lb. 8½ ozs. when dried
10 " " " " " New Hawthornden ..	" 1 " 11 " " "
10 " " " " " Blenheim Orange	" 1 " 12 " " "
10 " " " " " Frogmore Prolific	" 1 " 9 " " "

The parings and cores have to be added to the weight of the dried fruit when calculating the exact reduction by evaporation. For Plums the temperature required is about 250°, and the time taken is from eight to ten hours.

The Committee marked their approval of the success of the experiments by recommending a silver-gilt medal to Messrs. Mayfarth and Company for the apparatus, with the expression of their great satisfaction at the results achieved.*

PRIZES FOR FRUIT.

The first prize for ten dishes of Apples, four dessert and six cooking, was awarded to Mr. A. W. Porteous, The Gardens, Devonhurst, Chiswick, who staged Bismarck, very fine; Gravenstein, well coloured; Worcester Pearmain, Ribston Pippin, very good; Cox's Orange Pippin, The Queen, good; Peasgood's Nonesuch, Warner's King, and Lord Derby, very fine. J. W. Melles, Esq., Sewarstone Lodge, Chingford (gardener, Mr. Nicholson), was accorded the second prize, staging fine examples.

For six dishes of dessert Pears, J. W. Melles, Esq., was awarded first prize, staging some fine fruits of Marie Benoist, Pitmaston Duchess, Beurré Diel, Doyenné du Comice, Louise Bonne of Jersey, and Rivers' Princess. In the same class the Duke of Northumberland, Sion House, Brentford (gardener, Mr. Wythes), was accorded the second prize for good examples of Marie Louise, Duchesse d'Angoulême, Beurré Diel, Pitmaston Duchess, and two others.

Mr. J. Hudson, gardener to Messrs. de Rothschild, Gunnersbury House, gained the first prize for six bunches of Grapes, staging two bunches each of Lady Downe's Seedling, Muscat of Alexandria, Black Alicante, which were very fine indeed. The second prize in the same class was accorded to Mr. Thos. Osman, The Gardens, Ottershaw Park, Chertsey, who staged good bunches of Black Hamburgh, Black Alicante, Mrs. Pearson, and Lady Downe's. Miss C. Debenham, St. Peter's, St. Alban's, also staged six average bunches.

The first prize for six bunches of the best flavour was taken by Mr. Thos. Osman with Mrs. Pearson, Muscat of Alexandria, and Mrs. Pince's Muscat.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair), Rev. H. H. D'Ombraim, Messrs. B. Wynne, R. Dean, H. Herbst, Chas. T. Druery, C. F. Bause, Robt. Owen, George Phippen, R. B. Lowe, T. W. Girdlestone, W. C. Leach, W. Furze, Geo. Gordon, Chas. Jefferies, Henry Cannell, James Walker, T. Baines, John Fraser, Chas. Noble, Bennett Poë, George Paul, Harry Turner, and Owen Thomas.

Mr. W. C. Leach, Albury Park Gardens, Guildford, contributed a collection of autumn foliage, rich in colour; Acer palmatum purpureum, Prunus pissardi, Rhus cotinus, Cerasus padus, Azalea pontica, Andromeda arborea, Pavia macrostachya, and others being included (silver medal).

Mr. H. B. May, Dyson's Lane Nurseries, Upper Edmonton, staged a very fine group of foliage plants, including well grown specimens of Pteris tremula elegans, Nephrolepis davallioides furcans, Davallia elegans, D. Mooreana, Croton Bergmani, C. Thompsoni, Adiantum farleyense, and various Palms (silver-gilt Flora medal). Messrs. E. D. Shuttleworth and Co., Peckham Rye, sent a group of Cycads, including some magnificently grown specimens (silver-gilt Flora medal).

Mr. Wells, Earlswood Nurseries, showed a small group of Chrysanthemums, including good flowers of Bouquet des Dames, James Salter, La Chirine, Elaine, Volunteer, Fabian de Mediana, Refulgens, and a dozen lovely blooms of William Wells. Mr. T. Bones, Tower House Gardens, Chiswick, sent three very finely flowered plants of Nerine crispa, which were most charming. Mr. Owen Thomas, The Royal Gardens, Windsor, staged a group of Margaret Carnations, which were in flower, they having been grown from seed sown on February 18th, 1892. The blooms, which are sweet-scented, partake more of the Pink than the Carnation, as also does the foliage. They will doubtless become very popular, as they are so useful for cutting purposes, and having such a delightful scent will still further enhance their value.

A group of very fine seedling Begonias was staged by Messrs. H. Cannell & Son, Swanley, Kent. The Zonal Pelargoniums exhibited by the same firm, and including Raspail Improved, Madame Bondeville, were magnificent; the latter of a delicate rose pink, is very fine (award of merit). Raspail Improved has much larger flowers and trusses than the original, and is a most decided improvement (silver Banksian medal). Mr. Arthur Knowles, nurseryman, Horsell, near Woking, exhibited a box of the charming Daphne cneorum, the plants of which were excellent specimens. Dr. Frankland, F.R.S., The Yews, Reigate (gardener, Mr. Ritchings), staged a group of Chrysanthemums (bronze medal). Mr. Anthony Waterer, Knapp Hill,

* See our Home Farm article, page 365.

Woking, was accorded a vote of thanks for a bunch of *Berberis Thunbergi*.

A hybrid *Streptocarpus*, crossed between *Galpini* and *Rexi*, was sent from the Royal Gardens, Kew. It is a very beautiful flower, the colour being clear mauve blue with a velvety violet throat, in which respect it differs from *Galpini*, which has a pure white throat and was staged for comparison.

ORCHID COMMITTEE.—Present: Dr. Masters (in the chair), Messrs. de B. Crawshay, E. Handley, J. Douglas, G. Hill, J. Jaques, Jas. O'Brien, H. M. Pollett and H. Williams.

Messrs. B. S. Williams & Son, Upper Holloway, had a diversified group of Orchids, flanked by a few plants of the beautiful *Griffinia hyacinthina*. A fine specimen of *Cypripedium insigne* was conspicuous; *C. cernanum superbum*, *C. selligerum rubrum*, *C. Dominicanum*, *C. Hartwegi*, *C. Morganiae*, *C. Spicerianum*, *Dendrobium Goldiei*, *Odontoglossum mirandum*, *O. grande*, *Pleione lagenaria*, *P. Wallichiana*, *Bollea Patini*, and *Oncidium Papilio Eckharti* being also represented (silver medal). Messrs. F. Sander & Co., St. Albans, had an interesting group, which comprised a very pale form of *Dendrobium Phalaenopsis Schroderiana*, *Cœlogyne fuscescens*, *Dendrochilum Lobbianum* with sixteen racemes, *Cattleya Brymeriana* (a brightly coloured form of the eldorado section, the lip being very rich, supposed to be a natural hybrid between *C. eldorado* and *C. superba*), *Masdevallia Gorgona*, *M. Roezli*, *M. chimæra*, *Cattleya chrysotoxa* (a richly marked flower with aurea characters, being deeply veined with gold, the sepals and petals pale yellow), *Brassia maculata*, and a charming pure white *Masdevallia* named *Measuresiana*, a cross between *M. amabilis* and *M. tovarensis*. Phillip Crowley, Esq., Waddon House, sent a good plant of *Vanda tricolor*, *V. Kemballiana*, and *Odontoglossum grande*, freely flowered. He also contributed *Cymbidium giganteum*, with a spike containing nine of the dark bronzy flowers (bronze Banksian medal).

CERTIFICATES AND AWARDS.

Chrysanthemum Mrs. C. Myers (Mr. R. Owen).—A white Japanese with broad, evenly disposed, and gracefully arched florets (award of merit).

Chrysanthemum Baron Hirsch (Mr. R. Owen).—A very promising incurved, having broad, substantial petals of a reddish bronze hue. The flower was not quite up, and will most likely turn out well (award of merit).

Chrysanthemum William Seward (Mr. Seward, gardener to J. Shrimpton, Esq.).—A handsome Japanese with broad florets of a deep brownish crimson, central ones reflexed, and greyish bronze (award of merit).

Chrysanthemum Beauty of Exmouth (Mr. W. J. Godfrey).—This is a fine white Japanese, figured and described elsewhere in the present issue (award of merit).

Zonal Pelargonium Madame Bondeville (H. Cannell & Sons).—Pale flesh pink, edged Picotee-like, deep rosy red, very fine truss.

Zonal Pelargonium Improved Raspail (H. Cannell & Sons).—A decided improvement on the well-known F. V. Raspail, the blooms and trusses being much larger (award of merit).

MR. W. CARRUTHERS ON "CYCADS."

The subject of the lecture given at the Drill Hall on Tuesday afternoon was "Cycads," and was most ably dealt with by Mr. W. Carruthers in the short time at his disposal. Dr. Masters occupied the chair.

In opening the lecture Mr. Carruthers remarked that a few years ago it would have been very difficult for anyone to have said what Cycads were; but of late years a very great interest had been taken in them by botanists, thus making it now an easy matter to identify them, and tell from whence they came. They had been allied with the Palm in each case erroneously, though it has since been demonstrated, and is now generally accepted, that they are related to our Conifers. He gave a few remarks on the hybridisation, remarking that the flowers of the Cycads have no stamens. There are, the lecturer went on to say, about 400 known species, which are found on almost all of the great continents. Their natural habitat appears to be the tropics, though they are found extending in a northerly direction, and also a southerly one, from the tropics. A large group is found in Florida, others in Mexico, South Africa, Tropical Australia, Asia, and on the borders of the Indian Ocean. The species with imbricated cones are found mainly in Mexico, and the various other kinds from the different quarters of the globe already named. One leaf shown by the lecturer had no resemblance to any of the others, but was more like a Fern, amongst which it was originally classed, until the botanists proved it to rightly belong to the Cycads.

The plants are all very easy to cultivate, requiring stove heat to bring them to perfection. Mr. Carruthers said he failed to understand how it was that plants of such easy culture, so beautiful and so useful for decorative purposes, should be so seldom grown. He would like to warn those who might be intending to grow Cycads not to throw them away if they did not at once break into growth. The plants remained dormant for a very long period, and would then suddenly start into growth.

Mr. Watson, Kew Gardens, in the brief discussion which followed, described the method of culture required, and said that, although *C. revoluta* would live in a temperate house, it would not grow, needing as it did a stove temperature to bring it to perfection, and show to advantage its fine green foliage. Professor Henslow remarked on the principal botanical points connected with Cycads. A vote of thanks to Mr. Carruthers and the authorities at Kew Gardens concluded the proceedings.

CLETHRA ALNIFOLIA.

WHEN this dwarf, hardy summer-flowering shrub is blooming freely, it is extremely attractive. Spikes of flowers, many of them much larger than those shown in the engraving (fig. 49), are produced from every axil; indeed, so freely have we seen the flowers produced that the low bushes bristled with them. They are creamy white in colour, delicately fragrant, and, associated with the fresh-looking light green foliage, are admirably adapted for vase decoration.

Being a native of the swamps of Virginia it requires moist, deep, and tolerably rich soil. It is worthy of a suitable position in the front of shrubberies, or even in large borders of herbaceous plants that are grown for affording flowers for cutting. It is deciduous, quite hardy, and although introduced in 1731 is not so generally

FIG. 49.—CLETHRA ALNIFOLIA.

grown as it might be. It is of close and rather compact habit, and grows about 3 feet high. The present is a good time to plant this useful shrub.

EFFECTIVE FLOWER BEDS.

I NOTICE you have been giving a list of flower beds which have been thought worthy of notice during the past season.

The following bed has been greatly admired, and is still good:—*Hyacinthus* (*Galtonia*) *candicans* and *Agatheæ cœlestis*. The *Hyacinthus* were planted in April about 10 inches from bulb to bulb, and the *Agatheas* were planted in June.

A second and very pretty arrangement was composed of *Fuchsia Charming* and yellow *Violas*. The *Fuchsias* were rooted in September, 1891, placed in 3-inch pots in March, and shifted in April into 6-inch pots. They were 18 inches in height when planted in June; the *Violas* were rooted under handlights the same month and planted as a ground-work at the same time.

A third and a very much admired arrangement consisted of *Gladioli breuchleyensis* and *Phlox Drummondii* planted underneath. When these beds were at their best at the end of August they presented a very gay picture and one well worth repeating. The *Phloxes* are still as gay as ever.

Another effective association has been produced by planting a dark

crimson Calceolaria in the centre of a long bed, a broad band of Henry Jacoby Pelargonium next to this, a broad band of Flower of Spring next, a broad band of Lobelia (blue) next, and a broad band of Ajuga reptans purpurea to finish with. This is a good hardy plant for edging, and gives very little trouble.

A fifth (circular) bed was planted as follows:—Centre, dark-leaved Cannas interspersed with pink Ivy-leaved Pelargoniums, a broad band of Rev. F. Atkins Pelargonium, and a band of mixed Phlox Drummondii pegged down. This formed a bold and effective bed.

The beautiful tuberous Begonias have played an important part in the flower garden; beds of these, with Mesembryanthemum cordifolium variegatum were very gay. Where the Begonias can be planted in separate colours they are far superior to Pelargoniums; they flower more freely, and no cuttings have to be taken to mar the effect. Where there are large beds and borders to be filled the old Rudbeckia Newmanni and Salvia patens form very bold and telling masses.—T. A., Cirencester.

PINK IVY-LEAVED PELARGONIUMS AND MARGUERITES FOR BEDDING.

"I AM asked to furnish two large beds with pink Ivy-leaved Pelargoniums and Marguerites. Will Mr. Dunkin, who wrote on page 280 in the Journal, please let me know the varieties he has proved best for the purpose, and the distance apart for the Marguerites to have the most effect?"

Thus writes a correspondent, and I have pleasure in detailing a little more of my experience. Madame Crousse is the best Ivy-leaved Pelargonium I have yet tried for bedding purposes; the colour is generally described as a delicate rose, but outdoors it may correctly be termed a true pink, as the colour gradually changes from rose to pink after the flowers have been opened a few days, and there is no other bedding plant I know of which supplies such a beautiful shade as does this. Wherever it is seen in good condition by those who have not grown it, a determination to do so in the future is invariably the result. This variety is a capital grower, producing abundance of long trailing shoots, especially adapted for pegging down. Old plants, which have become too tall for pot culture, may be turned to good account by planting them in the flower beds and intermixing a few young ones with them. Both old and young plants flower very freely in our soil, which is light and well drained.

Rather close planting should be practised so as to produce a good effect quickly. When our plants are pegged down the points of the young shoots are regularly disposed at about 2 inches apart all over the bed, a mass of flower is then speedily produced. The only attention required for the rest of the season is to stop a few of the strongest shoots, cutting out an occasional one where the growth is becoming crowded, and keeping dead flowers removed.

Souvenir de Charles Turner is a good bedding variety, of a rosy magenta colour, the individual pips of each flower truss being large and full. The shoots produced are thicker than those of Madame Crousse, but they do not grow so freely; and although the colour is richer than that of the former variety, it is not generally so much admired.

The Marguerites when put out should be strong plants, root-bound in large 60-size pots, the stems having been stopped twice. This will cause them to flower freely instead of starting rapidly into growth after being planted out—a most important consideration. The beds I planted last year were large oblong ones, 4 feet in width. Only one row of Marguerites was planted, these being dotted along the centre at intervals of 3 feet, a distance which answered admirably for plants of the size above indicated. If, however, I were to plant a round bed, or one which required two or more rows of Marguerites, I should place them 4 feet apart, as it is important to allow plenty of pink to show between them to produce the best effect. If at any time the Marguerites show a tendency to grow too strongly a few of the Pelargonium shoots should be turned back, and the roots of the Marguerites cut round with a spade at about 6 inches from the stem. In this way they can be kept within due limits and constantly flowering throughout the season.

Mrs. Perry Pelargonium, Cineraria maritima (pegged down), or Centaurea ragosa each make a good edging for a bed so planted. Last year, however, I edged one bed with a broad band of Golden Feather, and I was told by an artist of repute that the dark green of the Ivy-leaved Pelargoniums, their pretty pink flowers, and the golden edging, when considered as a combination of beautiful shades of colour, was simply perfection.—H. DUNKIN, Castle Gardens, Warwick.

FRUIT FORCING.

Vines.—*Earliest Vines in Pots.*—In a previous calendar we enlarged on the desirableness of taking the early supply of sweet, thin-skinned Grapes from Vines in pots, in preference to starting permanently planted Vines at an early period. Well managed Vines in pots produce

Grapes that are quite equal in quality if not in size to those borne by Vines planted in borders, and often better, from the conditions of culture being more favourable. This is the case where the Vines are given the benefit of bottom heat, but to insure success the canes must be sufficiently strong, thoroughly ripened, and duly rested. As a start must be made the 1st of November to have ripe Grapes in March or early in April, the materials for affording bottom heat—that is, tree leaves and stable litter—should be in due course of preparation. The heat about the pots must not exceed 65° at the start, bringing up the fermenting materials to the level of the pots by degrees, so as to augment the temperature to 70° to 75° about them when the Vines are in leaf. Any Vines in pots required for starting later should be placed under cover, an open shed with a north aspect being suitable, but the pots must be protected with dry hay or straw, and mice and rats kept down, or the animals may render the Vines useless by girdling them at the collar.

Vines for Starting in December.—The pruning will have been performed; if not it must not be further delayed, as early and complete rest for a few weeks contributes to an even break, the Vines responding to the heat and genial atmosphere better than when little rest is given. Pruning to two buds is usually followed by a good show of useful bunches; but if such have not done so in previous years, or larger bunches are desired, the shoots may be left a little longer, or pruned to the most plump eye nearest the base; but what is gained in size of bunch is generally lost in compactness of bunch, unevenness of berries, and bad finish. Bunches of 1 to 2 lbs. weight are quite large enough for early Grapes. Remove any loose bark, but avoid the close peeling and scraping that injures the rods, and wash them with tepid soapy water—3 ozs. of softsoap to a gallon of water. If there has been any attack of insects follow with an insecticide, and repeat before the Vines are started. Thoroughly cleanse the woodwork of the house, and limewash the walls. Remove the surface soil down to the roots, if not to the whole extent of the border, for a distance of 3 or 4 feet from the stems, and supply fresh loam so as to encourage fresh roots as well as an extension of those from the collar, adding about a quart of steamed bonemeal and a gallon of wood ashes to every three bushels of loam. Keep the house cool, airy, and dry until the time arrives for starting.

Houses of Ripe Grapes.—Thin-skinned Grapes are more susceptible to damp, cold, and climatic changes generally than the thick-skinned. This applies equally to Hamburgs as to Muscat of Alexandria, but Hamburgs require 5° less heat, 50° being necessary for the good keeping of Muscat of Alexandria; and there must not be any deficiency of moisture at the roots, otherwise the Grapes will shrivel. Remove all dead and decayed leaves from the Vines where ripe Grapes are hanging, and look over the bunches for any shanked or decayed berries, and burn them. A temperature of 50° is the most suitable for Muscat of Alexandria, but it may fall to 40° where Black Hamburg is hanging. No opportunity should be lost in giving air when the days are fine, turning on the heat so as to cause a gentle warmth in the pipes, not so much to dry the atmosphere as to insure a circulation of air, which is the best safeguard against damp. Turn off the heat at midday or soon after, so as to allow the pipes to cool, but not so as to lower the temperature below the night minimum. When the heat falls too low and the temperature is raised moisture condenses on the berries, and being stagnant the skin of the berries is more or less decomposed, and the micro-organisms find easily access to the pulp, or secure the needful food elements in the weakened epidermal tissues, and set up speedy decay. There is no harm in a low night temperature; the fault lies in not giving air soon enough, so that the heat from the hot-water pipes or the sun expands the atmosphere, and the moisture is deposited on the cooler surfaces of the berries as well as on the glass. In dull weather, especially during fog, it will be necessary to keep a genial warmth in the pipes, but the house closed, in which case the moisture will be condensed on the glass instead of the Grapes.

Vines not Ripening the Wood.—Any that are not yet hard and brown in the wood should have a temperature of 60° to 65° by artificial means, a little air constantly, and the heat from sun heat may run up to 85° or 90°, only let there be enough air to insure a circulation. The laterals should be reduced by degrees, bringing them down to their principal buds, and when there is no danger of starting those, the shoots may be shortened to about two leaves above the pruning buds. This will cause the latter to plump, and by keeping the house rather warm by day with ventilation, and turning off the heat at night with free ventilation, the Vines will go to rest.

Late Grapes.—The thick-skinned Grapes require time to mature after they are ripe, though Alicante improves nothing whatever in keeping, and is at its best so soon as well ripened, and the same may be said of Gros Maroc. Mrs. Pince is the best thick-skinned Grape, and it is one of the most difficult to finish, and it is at its best shortly after it is ripe. Its great defect, however, is not colouring well up to the shank, and it makes no difference whether the bunches are large or small. Started early, say in March, the berries set better and the fruit ripens quite up to the shank, and when covered with its fine bloom is very taking in appearance. Alicante retains its colour well, and as a prelude to Gros Colman is a very desirable Grape, as it is good in quality, the vinous flavour being very refreshing, and the earthiness of Gros Colman entirely absent, whilst its appearance is unrivalled by any oval Grape unless it be Alnwick Seedling. The magnificence of Gros Colman is not its chief merit, and that goes a long way even with table Grapes, and is all-important for market. Its beautiful appearance whets the appetite, and the flavour is entirely overlooked, as that beside West's St. Peter's, less

presumptuous in bunch and berry, is incomparably bad, yet when started early so as to allow it time to mature, the berries are not only superb, but the quality is vastly improved. But its principal value consists in the easiness of its growth; the bunches are always compact, the berries set well; they swell to a good size, and when the Vines are not overcropped they colour first-rate. It is far the best in quality when grown on the old red sandstone formation, though it does well on the alluvial silts, as do all the coarse vinous Grapes. For rich vinous quality no thick-skinned Grape can vie with West's St. Peter's, but it is no use where appearance at table is the chief merit in a Grape. Lady Downe's is not only the best keeping Grape, we have had it excellent in June, but is unapproached by any late Grape for uniform excellence in quality, though only about half as taking in appearance as Gros Colman, and not giving nearly as much weight of fruit per Vine or space, it retains its richness to the last, simply because it contains more sugar and mostly has a decided "smack" of Muscat. In white Grapes we have the White Gros Colman, which is less earthy in flavour than the type, and promises to take a high place for appearance sake. Trebbiano will not, however, go out of cultivation, for when well done it is an enormous counterpart of Muscat of Alexandria in looks, and the flesh is firm, crisp, and sweet. This Grape also likes red soils. There must not be any deficiency of moisture in the border, and the atmosphere must not become stagnant, but have enough warmth, with air, to keep it in motion, the temperature not being allowed to fall much below 50° until the leaves fall.

Renovating Vine Borders.—Where the soil is of a suitable nature and the cultural treatment proper Vines flourish for an indefinite period, but they are mostly planted in artificial borders and the roots confined to limited areas. These conditions result in the soil becoming defective in aliment if not unfavourable as a rooting medium. Thorough renovation in ordinary cases is desirable, but a partial renewal of the soil, or such portion of it as will secure active feeders, is generally attended with satisfactory results. Where, therefore, Vines are not in a satisfactory condition no time should be lost in removing the soil down to the roots and picking it from amongst them, so as to displace as much of it as possible with fresh compost, and it is best effected whilst the leaves are upon the Vines, but not before they have performed functions to the extent of perfecting the buds and wood. In case the border is found very unsatisfactory and the roots few and deep, it will be necessary to remove all the soil and renew the whole border, commencing with the drainage, which should be clear and 9 to 12 inches deep, with a 3-inch layer of fine material on the top, old mortar rubbish freed of pieces of wood answering perfectly. There must be a drain under the drainage to carry off superfluous water. The soil should consist of the top 2 or 3 inches of a pasture, where the staple is a good yellow or hazel loam. A barrowload of charcoal may be added to every cartload of loam and a similar proportion of calcined oystershells, though they are preferably crushed, also a bushel of wood ashes and a peck of Thomas' phosphate powder, all well incorporated. Two feet depth of compost is ample, and the roots should be laid in the top foot and in layers according to their inclination, encouraging those from near and at the collar by laying them just beneath the surface, making the whole compact and having the soil moderately dry. If the roots are inside and outside one part may be done one year and the other the next, without any danger of loss of crop. Take care to preserve all the roots practicable, merely cutting off broken and paring bruised ends smooth, and to keep them as much as possible from the drying influence of the weather whilst the operation is in progress. Afford a good watering to settle the soil about the roots; if necessary, sprinkle 4 ozs. of steamed bonemeal on every square yard, and mulch with about an inch of short manure, and cover outside borders with a few inches thickness of leaves with a little litter over them.

Melons.—The supply of fruit from frames and pits heated by fermenting materials is about over, yet fairly well-flavoured Melons may be had up to November, and it is a notable fact that the scarlet flesh have more quality and taste than the green flesh, about two-thirds of which are white fleshed. Little Heath and Scarlet Premier are examples of rich flesh, the latter being very good for late work, keeping a considerable time, and so continuing the supply to a late period. Any fruit yet remaining should be cut with a good portion of stem when approaching ripeness, and placed on a shelf in a house with a gentle warmth, where they will ripen and be welcome additions to the dessert, quite as much from their appearance and aroma as for use. The supply of fruit from houses will be continued for some time longer, often till Christmas, the later fruit only being now swelling. Damping in the morning and again early in the afternoon will be sufficient for these plants, and water need only be supplied to the roots once a week, unless they are very much restricted, when it will be required oftener. Let the foliage have as much benefit as possible of the autumn sun by keeping superfluous laterals suppressed, not allowing them to interfere with the principal leaves. Keep plants with fruit approaching ripeness rather dry at the roots, and withhold water from the atmosphere, and maintain a brisk heat of 65° at night, 70° to 75° by day, rising to 85° or 90° from sun heat, affording a little air at the top of the house constantly, and increasing it whenever the weather is favourable.

Cucumbers.—Maintain a night temperature of 65° to 70° in mild weather, 60° to 65° when the nights are cold, 70° to 75° by day artificially, advancing to 80°, 85°, or 90° with sun heat. Admit a little air at the top of the house whenever the weather is favourable, but avoid cold currents; indeed, it must be done without lowering the temperature or drying the air too much, and lose no opportunity of closing early in the

afternoon on days when a little ventilation has been given in the early part of the day. On dull days little moisture will be required, but on very fine days the plants may be lightly bedewed overhead, and the floors, walls, and paths damped in the morning and afternoon, also when much fire heat is used in the evening. Earth the roots as they protrude from the hillocks or ridges; supply water as required, not less in temperature than that of the bed, being careful not to overwater, nor allow the plants to lack needful supplies of that element and liquid manure, or surface dressings washed in.

The autumn fruiterers being in full bearing must not be overcropped, but the plants will bear enormously. Cut the fruit directly it becomes fit for use, also remove tendrils, male blossoms, and an excess of fruit blossom or deformed fruits. Supply a little fresh loam to the surface of the beds as often as the roots appear, and let it be warmed through before using. Examine the plants at least once a week for the removal of bad leaves, and for stopping and cutting away the superfluous growths. Horse droppings sprinkled on the beds occasionally act as a gentle excitant to the roots, supply nourishment to the soil, and ammonia to the atmosphere. Spare no effort to keep the foliage clean and healthy, and do not allow accumulations of dirt on the glass. Allow the winter fruiterers to extend well up the glass before stopping them, train the shoots right and left at about 1 foot distance apart, crowding being fatal to well developed foliage, and the sturdier the plants are grown the better will they be able to withstand the trying ordeal of continued dull or prolonged severe weather.

PLANT HOUSES.

Cyclamen.—Seedlings may be carefully pricked out of the seed pan into other pans or shallow boxes until they are large enough for small pots. The young plants should be arranged close to the glass in a temperature of 55°. Air ought to be given to prevent the young plants becoming drawn. If the young plants are large enough for small pots keep them plunged after potting to prevent dryness. A temperature 5° lower will do for plants in this stage. Larger plants in 3-inch pots may be placed into 5-inch; these should be grown under cool conditions, and will if properly treated be useful for early flowering another year. These plants will produce a few flowers in spring, but they should be removed as they show bloom and the plants encouraged to grow. Seed may be sown at once and placed in a temperature of 60°; in fact, the seedlings should be kept in heat during the winter. Excellent plants may be produced from seed sown at the present time. These plants can readily be brought into bloom as they are required by placing them after they once show flowers where a little warmth can be given them.

The Forcing House.—Where quantities of flowers are needed, a house in which a hotbed can be made should be set apart for forcing them. Leaves are now plentiful, and if those of the Oak or Beech are gathered and mixed with litter from the stables, the bed will retain heat for a long time. Where leaves form the principal part of a hotbed, it may be made up at once in the house, but when litter largely predominates, the material should be thrown together outside and turned two or three times before the bed is made. When the bed is made up in the house a liberal quantity of air should be admitted to aid fermentation. Azaleas and any other plants that it is necessary to force into bloom may be stood on the surface as soon as the material begins to heat. Roman Hyacinths come forward rapidly on a bed of this description. It is also an excellent place for Bouvardias until the whole space is needed for other things.

Solanums.—Where a stock of these are needed for another year introduce a few plants into warmth and force them into growth to yield cuttings, which, when large enough, should be rooted, and the young plants grown in heat. Seed may also be sown, and the seedlings grown in the same way. When raised at once the plants have a long season before them in which to grow and set their berries.

Lilium lancifolium.—These have done flowering, and the plants should be protected from frost until they ripen off naturally. A deep frame or a position at the back of a cool fruit house will suit them very well. The bulbs must not be kept too dry after the stems have died down.

Fuchsias.—A late batch of these are very useful for conservatory decoration, and prove conspicuous in association with early flowering Chrysanthemums. The sprays of bloom are also servicable in a cut state; they are a little heavy, but in large vases they hang very gracefully over flowers of a stiff nature. Those that have done flowering may be stood outside for a time until the approach of frost, the wood will become firm and ripe, and the plants are ready for storing away for the winter.

Tea Roses.—Plants that have been well cared for outside during the summer and lately protected from frost in frames or a cool house may be introduced into a structure where the temperature will average about 50°. A little air should be given, and in bright weather the plants syringed twice daily. Under these conditions they will soon start into growth, and in due course produce a useful supply of flowers. The plants introduced a month ago have commenced to unfold their delicate buds, and are useful now that outside flowers are practically over. Roses that are to be introduced into the forcing house early in December may remain outside until they have been subjected to a few degrees of frost.

Lily of the Valley.—The foliage will have died down from plants that were grown inside by the aid of warmth in spring, and then plunged in a sunny position outdoors. These will soon come into bloom if they

are introduced into brisk bottom heat. Very early supplies can only be obtained by this means.

Tuberoses.—Tubers potted late and grown outside during the summer and lately sheltered in a cool house will be useful if brought into flower. These, as a rule, are never so good as those that are brought into flower earlier in the year. The flowers are, however, highly appreciated. They will come into flower quickly in a temperature of 55°. After flowering the plants may be thrown away.

THE BEE-KEEPER.

APIARIAN NOTES.

PREPARING FOR WINTER.

It should be borne in mind that the less honey bees require to consume during the winter the more healthy will the colony be. The best way to secure this is to prepare now and never more disturb the bees until the spring is advanced. One manipulation at the wrong time is sufficient to insure the destruction of the best hive. On no pretext whatever should cold air be admitted to the hive from above, and the more cosy they are kept the better.

Meadow hay forms the best protection to hives both on the sides and the top; a piece of felt should cover the hay on sides and a watertight roof of some sort raised a little from the hay with ample ventilation at the eaves. This covering is perhaps not quite so neat-looking as wood, and loose hay never looks well in an otherwise well kept garden.

Outside cases are sometimes heavy to lift, and always occupy the same space whether tenanted or not. A good substitute, and much better in most respects, are four panels or shutters the full height of hive and two tiers or supers. Perhaps the cheapest and most simple plan of fastening these together is by brass screws, two in each side. The wood should not be more than half an inch for the uprights and three-eighths for the bars. That size is necessary to cover handles and fastenings.

This makes a neat and cheap cover which anyone can make, and is a thorough protection against wind and water. If desirable, the space between the bars may be filled with hay, or a piece of felt may be tacked on. Of course an entrance corresponding with entrance to hive must be left, and the roof may be from a sheet of iron or zinc to an expensive and as ornamental a roof as the bee-keeper may desire. This form of protection is the only one of double casing that prevents decay in hives.

WINTERING BEES.

On the 9th October the barometer rose in twelve hours from 28.20 to 29.40. Some flowers that had been in bud for weeks opened on that day, although the temperature was only 45°. We have now had a week of improved weather, although not a day has passed without rain. It has, however, been fair enough for farmers to proceed with harvest operations, which is late. On the 11th we had 7° of frost, which cut down all tender flowers.

As the weather previous to that had been so wet and stormy, which prevented hive manipulation, I took the advantage of the last-mentioned date to remove supers and feed those in want. As none of the bees hatched from the middle of August and onwards had evidently never flown. All the hives were very strong in bees, none apparently having been lost at the Heather. They, with the feeding and disturbance, had an airing, and, in all my experience, I never witnessed bees in the same state during the autumn, and never worse during any winter. Their evacuations covered everything thickly in the apiary. Thousands of bees were falling to the ground, and for a time were unable to fly. The sun shining revived them, and the greater number found their way back to their hives, although many were lost, but there are still plenty and to spare, never having had so strong hives at this season.

There has been more frost, storms, and rough weather since May than was in any of the winters between 1847 and 1849. The present year has afforded some useful lessons. Hives at the Heather, equal weight as some at home, consumed all their stores, while the latter were only several pounds down. The cause of this was the lower temperature the bees had to contend with at the Heather, consequently more food was consumed to keep up the necessary heat for their healthy maintenance. But it was evident that two months' confinement of young bees after being hatched was inimical to their welfare. Doubtless had the temperature been higher the long confinement would not have injured them to the same extent.

The experience is not new, but the proof is valuable, supporting

my previous experience and teachings how to prepare bees for the winter by giving them an ample sized hive, single walled, well covered with non-conducting material, ventilating floor, and small entrance, 1 inch being wide enough for the strongest hive. With such hives so prepared there will never be any dead bees found on the floor during the winter. Reverse matters. Crowd the bees on little space, have a solid floor, hive double walled, and a wide doorway, and the latter will be often full of dead bees, not unfrequently 1 inch deep of them on the whole part of the floor.—A LANARKSHIRE BEE-KEEPER.

TRADE CATALOGUES RECEIVED.

Dammann & Co., Naples, Italy.—*Vegetable and Flower Seeds, Plants, &c.*

P. J. Looymans & Zouen, Oudenbosch, Holland.—*Shrubs, Ornamental Trees, and Roses.*

T. Rivers & Son, Sawbridgeworth.—*Fruit Trees and Roses.*

Frank Cant, Braiswick Nursery, Colchester.—*Roses.*

••• All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Stove Climbers (J. M.).—Twelve good stove climbers are the following. If half the number only are required select the first six—*Stephanotis floribunda*, *Allamanda Hendersonii*, *Dipladenia Brearleyana*, *Clerodendron Balfourianum*, *Bougainvillea glabra*, *Gloriosa superba*, *Dipladenia amabilis*, *D. boliviensis* to be grown at the coolest end of the house, *Cissus discolor*, *Ipomoea Leari*, *Poivreia coccinea*, or more commonly called *Combretum purpureum*, and *Aristolochia elegans*.

Cypripedium insigne (E. M.).—We should consider a plant well flowered in a 10-inch pot if it had thirty good blooms. We have, however, seen plants in large pans with over one hundred blooms. A plant is well bloomed when it produces one bloom of large size for each fully developed growth; for instance, if a plant in the pot you name had only twenty fully developed growths and bore the same number of flowers, we should term it a well-flowered plant.

Maggot Infesting Palm and Grevillea Roots (H. E. M.).—This is the grub or larva in an early stage of one of the destructive weevils of the genus *Otiorhynchus*, probably *O. tenebrioides*. Like its brethren, it lurks at the roots of a number of plants growing on borders or in pots, feeding from autumn till spring. Where it occurs the roots need a thorough examination. Dressing them with lime or soot has been found successful. The soil may also be watered with hellebore tea, which is fatal to them, also lemon oil, and diluted carbolic acid has been tried; but the latter needs caution. They defy many of the insect killers. During the summer the beetles appear on the branches of fruit trees at dusk, and may be shaken off into trays or cloths. Roasting the soil, then moistening it prior to use, is an excellent preventive, catching the weevils a better. The "webs" have nothing to do with the grubs, but are the mycelia of a fungus.

Gathering Apples for Keeping (F. S.).—Apples for keeping should never be gathered before they part readily from the trees, for when they are immature there is great danger of their shrivelling, even when kept in a cool and dark room somewhat moist. Except in warm and early seasons the following are not fit to gather at the end of September, but require more time. Dessert: King of the Pippins, Cox's Orange Pippin, Blenheim Orange, Gascoigne's Scarlet, Wyken Pippin, and Baumann's Reinette. Kitchen: Small's Admirable, Queen Caroline, Lord Derby, Golden Noble, Bismarck, Lane's Prince Albert, and Bramley's Seedling. The following are generally fit to gather at the period you require them, and keep some little time. Dessert: Duchess of Oldenburg, Kerry Pippin, Worcester Pearmain, and Lady Sudeley. Kitchen: Lord Grosvenor, New Hawthornden, Councillor (Yorkshire Beauty), Ecklinville Seedling, The Queen, Warner's King, and Seaton House.

Lælias Decaying (*B. B.*).—The *Lælia purpurata* pseudo-bulb you sent is rotten. Insufficient drainage or too much moisture when resting will produce this result; a very low temperature will also cause them to go off. *Lælias* and *Cattleyas* require more sun and air than is generally accorded them; keep the plants much drier and let them have more light at all times.

Top-dressing Peach and Nectarine Trees in Pots (*Oakbank*).—The proper way is to remove the soil to such depth as will admit of an addition of fresh, and still leave room for holding water and top-dressings of rich compost below the rim; also to remove the soil at the sides, at least two-thirds the depth of the pot, so as to allow of some fresh soil being placed all round the ball and rammed well. We have not only seen the operation carried out at Sawbridgeworth, but have practised it ourselves for many years, and found it to answer well. You cannot do better than strictly follow Mr. Rivers' teaching, as given in his book, "The Orchard House," page 82, sixteenth edition, to which you refer.

Chrysanthemums Damping (*C. G. B.*).—It is very difficult to point out the cause of your blooms damping without seeing them and knowing exactly how they have been treated in every respect. If the plants are active at their roots, we are inclined to think they may have been left outside too long, and have been slightly checked. Damping is also due to a superabundance of moisture in the atmosphere and defective ventilation. During changeable weather the utmost care is necessary to maintain a uniform condition of moisture in the atmosphere. When the sun bursts out brightly, and ample ventilation is not quickly provided, the moisture of the atmosphere is condensed on the florets, and quickly ends in their destruction. The varieties you name are very liable to damp, especially in a house where a little fire heat may be used and the atmosphere close and rather moist. They always open best when housed before the flower buds are too far advanced, and where they can have liberal ventilation. Any attempt at hurrying them frequently ends in damping. With the best of men scores of fine blooms are often lost after a fog. It is possible that a few early buds on some of your plants may have been taken, and this will account for other plants running up so much taller on the same plant. Sometimes insects destroy the bud, and the shoot has to be allowed to extend again to form another bud. Sometimes they miss showing a bud that would develop into a good bloom. It is not uncommon to see buds on plants such as you describe in different stages of growth.

Retubbing Seville Orange Tree (*Pelargonium*).—The tree grown in an ordinary conservatory should be retubbed about the end of March or just before it commences to push its blossom buds. The tree should be kept rather dry, but not so much so as to distress the foliage, causing it to become and remain limp. If you wish to return the tree to the same tub, remove the drainage and pick out the old soil from the base, sides, and surface of the ball with the tine of an old fork, taking care not to injure the fibres more than can be helped, and if the ball can be reduced in that way so as to admit of an inch or a little more of fresh soil all round, it may be returned to the same tub, after it has been thoroughly washed and dried, and efficiently drained with clean drainage. But if the roots are very closely matted they must not be disturbed much, merely removing the drainage, loosening the sides of the ball, and removing the surface soil down to the fibres, then afford a new tub not less in diameter and depth than 2 inches larger inside measure than the old, nor more than 4 inches. This will admit of an inch or two, as the case may be, of fresh soil, under and around the ball, the smaller shift being best. The best compost is good fibrous yellow loam, cut 2 inches thick from an old upland pasture, torn up with hands; to this add one-fifth of decayed stable manure, and to each three bushels of the mixture a 9-inch potful of crushed half-inch bones, and the same quantity of charcoal in pieces about the size of a hazel nut, incorporating the whole thoroughly. The drainage should be good, and formed of clean broken potsherds, placed in carefully, and over them some loam fibre, raising it to the required height, and rammed firmly so as to keep the compost from mixing with the drainage. Keep the collar rather high, just above the general level, to leave room for water and surface dressings, say a couple of inches below the top, and make the compost firm about the ball, taking care not to leave any space unfilled, and just cover the upper roots with soil. Do not give water for a few days, but syringe the tree two or three times a day; and when the roots are working in the new soil apply water as required, maintaining a genial atmosphere. The soil should be moderate moist when used, and prepared a month or so previously and slightly warm. If the compost is cold and wet the roots will not take to it freely. The central mass or old ball of soil and roots must be moist, but not sodden when the work is done.

Names of Fruits.—*Notice.*—Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*A. Reid, jun.*).—1, Cellini; 3, Fearn's Pippin; 4, Court of Wick. (*Perseverance*).—1, Minchall Crab; 2, Bedfordshire Foundling;

3, Tower of Glamis. The box was much crushed and the labels were displaced. (*F. P.*).—1, Adams' Pearmain; 2, Norfolk Stone Pippin; 3, Sturmer Pippin; 4, Yorkshire Greening; 5, Northern Greening; 6, Beurré Diel. (*J. C.*).—2, Chaumontel; 3, Beurré Sterckmans; 4, General Todleben; 5, Van Mons Léon Leclerc; 6, Winter Hawthornden. (*F. J. Gray*).—1, Uvedale's St. Germain; 2, Red Doyenné; 3, Beurré Capiaumont; 5, Marie Louise; 6, Beurré Bosc. (*J. W. H.*).—Carlisle Codlin. (*G. J.*).—1, Queen Caroline; 2, Gloria Mundi; 3, Court of Wick; 4, Mère de Ménage. (*W. M. B.*).—Your Pear is certainly not Beurré Superfin, but probably Duchesse d'Angoulême. The only security for correct nomenclature is to procure trees from some recognised authority in the horticultural world. (*R. C. L.*).—The boxes of fruit that contained no letters in them were retained a week after our notification on page 319 (October 6th) and then had to be removed. We have now attended to all the parcels which contained letters with the fruit up to the latest date for naming (Wednesday morning, 19th inst.). (*Finglas*).—The Pear appears to be one of the many continental varieties that are, like the specimen, of inferior quality in this country.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*J. C. S.*).—*Odontoglossum hystrix*. (*Amateur*).—*Sedum spectabile*.

COVENT GARDEN MARKET.—OCTOBER 19TH.

MARKET very flat indeed, with prices much depressed.

FRUIT AND VEGETABLE FARMING.

Not market gardening at all; that is not what our title points to, but to the production of both fruit and vegetables—food for the people, upon a larger scale than has hitherto been

attempted. In the near future such green vegetables as winter greens, Brussels Sprouts, and Savoy's will only hold a place, and that a very secondary one, amongst vegetables for table use in winter. In the United States of America the evaporation of fruit has proved so successful and so profitable that vegetables have also been brought under the process, all kinds of vegetables being now evaporated. Peas, Broad Beans, Potatoes, Pumpkins, Vegetable Marrows, Carrots, Parsnips, Kidney Beans, and Tomatoes are all successfully passed through evaporators, the water being thus driven out, and all the nutritive properties retained in them. Vegetables so treated are available for use at all seasons of the year, being wholesome, nutritious, and palatable after ordinary cooking.

In the last quarterly number of the "Journal of the Royal Agricultural Society" Mr. Charles Whitehead has an article on "New Modes of Disposing of Fruit and Vegetables," in which he explains what is being done to extend the preserving of such produce. The matter is so important that we at once call attention to it, and we gladly acknowledge our indebtedness to Mr. Whitehead for much valuable information upon the subject.

Schemes for the extension of fruit farming are now being carried out, the land is in course of speedy preparation so as to be ready for the planting immediately after the leaves fall. What is the object in view of the planter? The general answer would probably be to obtain fruit for market. But that is not enough. Fruit growing, solely for market as fresh fruit, has often led to such a glut of one sort or other that profit has been impossible. No, the scope of the fruit grower must be much more comprehensive. It must include the sale of fresh fruit in the best way, fruit evaporation, jam, and fruit canning or rather the packing and preserving in the glass jars with metal lids which are fast taking the place of tin cans in the United States, because they do not impart any unpleasant flavour or taint of any sort to the fruit. These glass jars vary in capacity from a pint to two quarts.

Jam-making and jam factories are now in full force among the fruit farms of Kent and other counties; fruit-bottling is also making its way. Both things are well done. We have tasted several sorts of jam from an Essex factory, all of which were excellent, and there was none of the disgusting slime which is present in so much of the cheap jam now sold by grocers in London and elsewhere. With the growing demand for jam, adulteration has laid its foul grip upon the preserving pan. Let fruit farmers see to this, and by keeping genuine jam well before the public enable it to discriminate between the good and bad, and buy directly from farm factories. The Essex Company does this by sending the jam in large or small quantities, carriage paid. The fruit vans of the Swanley factories go far and wide into other counties as well as in Kent; that is precisely what is wanted—fruit well grown, skilfully preserved, profitably sold, a genuine article cheap and pure to the purchaser, profitable to the producer, untouched by the middleman. Co-operation tells here again; fruit growers combine, form a company, establish a factory, employ travellers, and thus sell their own fruit.

Well, let us go on then, this is only the beginning of things. Before us is fruit evaporation with all its marvellous possibilities, a large and ever-growing demand by the consumer, relief from the pressure of agricultural depression by the producer, employment for tens of thousands of our rural population. There is nothing vague or uncertain about it; climate, soil, and markets are all here. There is no doubt about the demand, a prompt and profitable sale is a certainty. Who will lead the way? Mr. Whitehead explains how the matter is wisely being taken up in Australia, and says, "The Queenslanders have been quick to see the advantages of the various systems of dealing with

fruit and vegetables that have been described, which are so profitably practised by the Americans, and there is no reason why they may not be successfully adopted in this country, both upon a large scale in factories and buildings for the purpose, as well as upon a small scale in the homes of the people."

We have no space for the details of fruit-canning this week; it must be explained in another paper, as it enters largely into every comprehensive scheme of fruit farming. It will suffice to add now one word of encouragement to fruit planters this season, and that is to remind them of an ever-increasing demand, of the probability of the growth of facilities for preserving fruit, so that fears of an overstocked market need not hinder them from planting.

WORK ON THE HOME FARM.

A recent journey through Derbyshire, Yorkshire, and Cheshire has enabled us to see how the corn harvest lingers in the north. The corn fields are very small, so small that the clearance of the crop strikes a visitor from the large corn-growing districts as a trifling thing, yet the work appears to proceed in a slow and unsatisfactory manner. Broken weather tells, but the first week of the present month was one of very fine weather in Derbyshire, and as we write this note in a Derby farmhouse, the weather is perfect. Our object in mentioning this is to remind dairy farmers of the importance of thorough cultivation of the small quantity of arable land they have. Curious, but true is it, that a small thing like this is so generally badly done on most farms. Take the large corn farms of East Anglia, and there the poorest land on the farm is almost invariably the few acres of permanent pasture. On dairy farms the same thing happens with the few acres of arable land. Yet rightly treated this particular portion of the farm should be so productive as to be of material use always, and a special resource in times of drought.

Late-sown Swedes are a light crop, but the roots, though small, are heavy and will winter well. Only in exceptionally cold districts would we clean and place them in heaps. In light or mixed soil on uplands this crop is most useful if left out till early spring for the ewes and lambs. There is then in ordinary seasons a nice crop of leaves for the lambs to run forward and eat before the ewe folds are made, and the labour involved in hoeing up root bottoms and setting folds is well repaid by the enrichment of the land. A slight browning of the tops of green Maize by frost is a reminder to use up the remainder of this useful green crop as speedily as possible. It has answered well this year, has helped to ease pastures a bit, so that there is a fair bite of grass now, and not the bareness which has already set some of our neighbours looking forward to difficulties about winter food for cows and store cattle. Well indeed will it be if they can be induced to bring their head of live stock well within the scope of their means, to sell all surplus or inferior animals at any sacrifice, and so to winter their store beasts that at turn-out time in spring they may go to grass in such fresh condition as to be ripe for the butcher by autumn. If money is to be made out of cattle now there must be systematic management; so as to fatten on pasture and not in winter stalls.

REMARKS.

- 9th.—Wet from 4.30 A.M. till 10 A.M., then a little sun and a storm rain 0.30 P.M. frequent sunshine in afternoon; clear night.
 10th.—Generally sunny in morning; spots of rain at 2.30 P.M.; sunny again later.
 11th.—Sunny all day; fine night.
 12th.—Bright sunny day, occasional cloud in afternoon; slight showers at night.
 13th.—Occasional sunshine, but generally overcast and spots of rain at noon.
 14th.—Steady rain from 2.30 A.M. to 9 A.M., then generally overcast, but occasional gleams of sun; spots of rain in evening.
 15th.—Fog till 10 A.M. (dense early), then sunny.
 A seasonable week, with a fair amount of sunshine. Temperature remarkably similar to that of the preceding week.—G. J. SYMONS.

IT is a very difficult matter to deal with and report on what appears so simple a matter as this, but, like several other things, it is not quite so easy as it looks. The circumstances and conditions under which the Rose is grown even in the narrow space of our own little island are so various that the estimate formed will be probably a good deal coloured by the person's own experience in his own locality. Moreover, there are various ways in which we regard the Rose season. There is first and foremost the exhibitor's point of view, and I suppose in nine cases out of ten where the character of the season is spoken of this is the matter uppermost in the speaker's mind; but then there is the secretary's point of view, where hard work and painstaking care may be all blown to the winds by an unfavourable day; and there is also that very numerous class of Rose lovers who never aspire to the honours of the exhibition table, but to whom the Rose is a delight, whether it ever wins a prize or not. Now, I am not an exhibitor. I have the opportunity of seeing a good many exhibitions, and some private gardens both of professional and amateur growers. I hear the opinions of many of them, and I ought to be able to form a pretty fair estimate of the character of a Rose season. There are a good many who in so doing have a thought of their own success or failure. They think of that storm which swept down upon them before they had time to cut the blooms, and so conclude that the whole season was a bad one.

Before the opening of each Rose season I receive a number of letters as to the prospects of the bloom. Like our weather forecasts, they are sometimes woefully wrong, although oftentimes they are the reverse. Amongst those which I received last June was one from the Rev. H. B. Biron of Lympne, who wrote very confidently about a fine Rose season, and I am inclined to think that he was right. Grand blooms have been exhibited, which linger in one's memory as none did last year, and although some of our shows were weak as far as the quality of H.P.s was concerned, yet grand blooms have been shown, while the move forward that Teas and Noisettes have made is remarkable. Grower after grower says, "I shall do away with or greatly diminish my growth of Hybrids, and go in for Teas." And this is no wonder when one thinks of their beauty, their delicacy of perfume (though a lady came to see my garden who said she hated the smell of Tea Roses), and their staying properties, for in this past season I have seen the same Rose exhibited in prize stands in shows two days apart. I could not help thinking, as I passed row after row of boxes of lovely Teas at the Crystal Palace, of what it used to be when perhaps only some half a dozen boxes were all that were seen of this beautiful and refined class.

I think perhaps the finest Hybrids that I have seen this past season were exhibited at Earl's Court at the International Exhibition on July 5th, three days after the National. I do not think that those who saw them will readily forget the magnificent stands of Mr. E. B. Lindsell in the amateur and Mr. Frank Cant in the nurserymen's classes. There is a finish in Mr. Lindsell's flowers that is unsurpassed, and what a glorious bloom of Horace Vernet was that in his stand, to which added glory was given, as it was from a cut-back. Then, has anyone ever seen anything like the blooms of Her Majesty exhibited by Mr. Frank Cant this year? If one could have any reasonable hope of getting such

blooms we might be induced to give her a space to herself, where she could not contaminate surrounding plants with her mildewy propensities to which she, Abel Carrière, and Jean Soupert are most grievously addicted. Then, how fine was the bloom of Gustave Piganeau shown by Mr. B. R. Cant at the Crystal Palace, and the lovely and brilliant bloom of Gloire de Margottin by Messrs. Merryweather & Son at Chester. One had looked upon it as a first-rate garden Rose, but its capabilities as an exhibition Rose was a revelation. Then, could anyone readily forget the magnificent stand of forty-eight blooms of Margaret Dickson, exhibited by the raisers, Messrs. A. Dickson & Sons of Newtownards? There was such a solidity of petal, such luxuriant wood and foliage, that this Rose cannot fail to win its way into favour; indeed, I do not see why it should not be regarded as the best white Hybrid we have.

Another Rose that I have noticed as especially good is Comte Raimbaud, a flower which is not grown so widely as one might have expected. Tea Roses have been marvellously well shown, and here and there general excellence has been such that it is not so easy to recollect the extra fine blooms as it is in the Hybrids. Many of the older favourites have been grandly shown. I do not think, however, that Comtesse de Nadaillac has been quite as well coloured as I have seen it. There have been some grand blooms of Souvenir d'Elise, which still maintains its high position, and comes in as the best Tea oftener, perhaps, than any other. Catherine Mermet and her daughter The Bride have been very beautiful; but really, as when one met the long array of boxes at our larger shows, the beauty of the Teas held one fast, and it was difficult to get away from them to their more showy rivals the Hybrids.

There is, of course, always a certain amount of interest attaching to new Roses, but it would almost seem as if the French raisers had got as far as they well can, for during the last two years I do not think that they have raised one Rose that is likely to be a valuable addition to our lists. There may, of course, be something that we have not yet seen, some "dark horse" which is to win the race, but since 1889 there seems to be an absolute dearth of them. I say since 1889, for in that year Gustave Piganeau came out. Now, with regard to this Rose, despite the fact that although it must be in comparatively few hands, and in small quantities, it has twice at the National carried off the prize medal for the best Hybrid, in both cases in the nurserymen's class. I cannot join in the chorus of praise which has been accorded to it, for I am afraid that is an indication of that vitiated taste which associates excellence with size. We do not want under-sized Roses, but neither do we want over-sized ones. I do not think that Paul Neyron or Ulrich Brunner are quite as much thought of as they used to be. No, it is to the home-raised flowers we must look now. I do not believe the French raisers take much care about hybridising, and where this is done one would hope for some such results as achieved by the late Mr. Bennett and by Messrs. Alex. Dickson & Sons. One of the former's Roses, of which he thought a good deal, Captain Hayward, was again exhibited this year, but I do not think it took very well; it has not improved, and is certainly under-sized. I believe the blooms exhibited at the Crystal Palace were not the first flowers, and hence perhaps their small size; but at the same time it shows it to be a very early Rose, too early for most exhibitions, and it is of that colour, bright red, of which we have so many. The same must be said of Charles Gater (Paul & Son), but this may improve, for one would like to see a really good Rose bearing the name of so thorough a rosarian.

Messrs. Dickson & Co. showed Jeannie Dickson in good form, and another grand Rose somewhat similar in colour, but entirely distinct in form and outline; it was Mrs. W. J. Grant, which obtained the National Rose Society's gold medal at Chester. I fear we are not likely to see much of it at present, for the stock has been purchased in America for a high figure, and will not be sent out until 1894. They had also another very fine Rose, which will

be put into commerce in May next—Marchioness of Londonderry. It is a very full and large flower of the Lady Mary Fitzwilliam type, and in colour white; but unlike that very miffy lady, vigorous in habit. In company with a friend I examined it closely at Chester and came to the conclusion that it was a grand bloom. At the same Show Messrs. Dickson had in their box of new Roses some promising flowers of some of which we shall hear more anon. The other day the raisers were good enough to send me a couple of blooms of the Marchioness of Londonderry, and they fully confirmed me in the opinion I had formed at Chester. At the same show Messrs. Harkness & Son exhibited two remarkable sports of Heinrich Schultheis, Merrie England and Mrs. Harkness, both oddly enough from the same shoot. The former, if it only remains constant, will be the best of all striped garden Roses; there is no muddling of colours about it, and it is a full Rose, unlike the Gallica Village Maid which so often goes by the name of York and Lancaster, (which it is not); moreover, being a Hybrid Perpetual, it is possible to obtain autumn blooms from it. There was nothing new in Teas that I can recollect, for Cleopatra is not new; and of Waban, of which some speak highly, I have not seen sufficient to enable me to judge of its merits; it is a dark pink from Catherine Mermet. Corinna (William Paul & Son) I thought a promising Rose and with a well formed pointed petal. I may here notice a Rose by no means a new one which I saw at Lord Brassey's residence at Normanhurst Court, Madame Ferdinand Jamin; it was only a buttonhole Rose but exquisite in its colouring, and planted out and allowed to ramble on the back wall of a house it gives thousands of exquisite blooms.

The personnel of the exhibitors has not varied greatly this season; some new men have come forward, some of the older ones have moved on, but there has not been much change. Colchester has held its high place as far as professionals are concerned; both the Cants have carried all before them. To the older goes the Jubilee challenge cup, to the younger the champion trophy, while probably the two best stands shown this year were Mr. B. R. Cant's stand at the Drill Hall, and Mr. F. Cant's at Earl's Court; and Colchester has yet another card to play. Messrs. Prior & Son have exhibited better this year than ever they have done, and occupied a higher position. The same may be said of Messrs. Merryweather & Sons of Southwell, who have exhibited in grand form, one of their Roses at Chester securing the medal for the best H.P. in the nurserymen's class.

I fear as far as Rose societies are concerned the past season has been a disastrous one. We all know how "upsetting" to a society is a wet day, and many a secretary who had laboured hard and striven to make his show a success was doomed to disappointment. Of the shows which I have attended this season three were held on the most execrable days that it was possible to be out in. I shall not easily forget Chester, nor do I think anyone will who had experience of it. What a sight it was when I entered the tent to see my good friend Page Roberts like another Atlas, not having the world on his shoulders, but valiantly holding up the dripping tent which threatened to swamp and mutilate his fine stand of herbaceous plants; he has well struggled with misfortune, and even had a Mark Tapley air about him, and so in many places exhibitors were trying to get their flowers out of the way of drip. The most provoking part of it was that had the show been held on the day proposed at first, it would have been fine, but the local municipal authorities willed it otherwise. Then Ipswich and Hereford were just as bad as bad could be; the former is said to be used to it, but it was a woeful contrast at Hereford to the glorious day of last year. I hear of other societies which have more or less suffered from the inclemency of the season.

There was but little change amongst amateurs, although there has been some. Mr. Lindsell is still the champion grower, but Dr. Budd ran him close, and secured the Jubilee trophy, and was first at a great many shows. Mr. Alex. Hill Grey is still the champion Tea grower, while in that same class Mr. A. Tate, of Downside, Leatherhead, and Mr. Herbert Fowler, of Claremont, Taunton, are likely to be forces with whom those who have hitherto held the foremost place will have to reckon. Mr. Orpen, of Colchester, has made an onward movement, and it is always pleasant to note that they who have begun in a very small way have advanced to a higher (if not the highest) place.

And now a word as to the Rose in the garden during the past year. The same causes which so interfered with Rose shows were also in force here. We had a grand flush of bloom, and then came heavy and dangerous storms to bring desolation in their wake. As an instance of this I had at the time of the Ipswich Show promised to visit my friend, the Rev. H. A. Berners' garden at Harkstead, but one of the most awful thunderstorms I ever experienced swept over the East of England the night before, accompanied with torrents of rain. When I met him on the morning of the Show he said, "It is hopeless, my garden is converted into a pond." I could

well believe it. Mr. Frank Cant, whose shed for setting up his Roses is some distance from his house, was imprisoned there for some hours and could not get home. Happily, in both these cases the Roses had been already cut, and when one looked at their splendid blooms a little doubt about the storm might have been felt; but alas! it was too true, and so it was that all through July, cold and dreary was too often the experience; but September made up for July, and during the fine fortnight that we experienced then I have never seen the Rose gardens so radiant. Teas we always look for, but the Hybrid Perpetuals put forth their claims to that title; for in my own garden—and I have heard the same from others—there was a great profusion of bloom, and that of Roses which might well have been July Roses. But after all, the glory of the Rose garden in the autumn is the Tea Rose. What lovely blooms one was enabled to gather of Catherine Mermet, The Bride, Madame Hoste, &c., and how very much they are preferred for house decoration to the Hybrids!

Nor must I omit the pleasure I have derived (and many others also) from the single Roses. What is there in colour to excel the Austrian Copper, or in pure rich yellow the Austrian Yellow? and to those who have space for it what a lovely thing is the single Polyantha with its sheets of white flowers absolutely covering the whole of the foliage; nor can one forget the treat given to us by Lord Penzance at the sight of those beautiful semi-double Roses he has obtained on the Sweet Briar. I believe that the Rose-loving world will have an opportunity of growing them, as they will be distributed by a well-known firm.

Such are my views of the Rose season of 1892 with its various advantages and disadvantages, and I think when we come to strike the balance we may fairly say that, although not quite up to the mark, it has been one out of which much enjoyment has been had. The fine weather of September has done much to ripen the wood, which is one of the most essential points for a good season in the ensuing year. The wet of the present month has greatly retarded the necessary operations; but perhaps a finer time may come, and rosarians are about the last persons to sit down in despondency, but hope on in the persuasion that there is "a good time coming yet."—D., Deal.

FUNCTIONS (AND WEIGHT) OF VINE LEAVES.

ALTHOUGH deeply interested in this discussion, it is with reluctance that I enter into it in any form. The weight given of Mr. Swan's Vine leaves, however, caused me to examine mine more closely than hitherto, and as the Vines are allowed a moderate extent of lateral growth, I considered the leaves to be fairly good. I cut some off, and their weight was exactly 1 oz. each, and measured a trifle more than 1 foot across. They were taken off two or three eyes from the main rod, and it is generally this portion on which small weakly leaves are to be found, especially if crowding by sub-laterals be permitted.

The Vines are planted and are growing in a span-roof house. The glass portion commences at 1 foot from the ground level, and the side shoots are encouraged to grow also from that height. The circumference of the rods at 9 inches from the ground is $6\frac{1}{4}$ inches, at 7 feet $3\frac{1}{4}$ inches. The border, an inside one, is composed of turf taken from a poor pasture ground, and old lime rubble only; but little feeding has yet been given. The Vines, the first season after being cut back, were allowed to make as much growth as possible, and when ripened pruned well back. The second season two bunches were left on each rod; the third, an average of 10 lbs. of fruit to each left to mature; the fourth, 16 lbs. This season the crop averages 20 lbs. to each rod, which is 10 feet long. Only one year did Gros Colman fail to colour well, the cause being over-cropping in this case. Both Vines and fruit have each season kept improving, with bunches and berries above average size.

Mr. Wright has, I believe, seen fruit exhibited from these Vines in past years, and this season we took some to Earl's Court on September 9th and 10th, which were awarded a silver medal. I have made some mistakes in their culture, but by those mistakes I have profited. Being over-anxious to have a good "set" I used the rabbit's tail too freely. Following the advice of a well-known grower, however, I used the tail less often, and was rewarded by having a perfect "set." Alnwick Seedling with us sets as freely as Black Hamburgh, and the berries swell remarkably well.

Madresfield Court perfected a good crop of fruit, extra large in size of bunch and berry. Seeing an article by Mr. Iggulden in the *Journal* in the summer 1891 on colouring Madresfield Court, I at once tried his teaching—namely, securing a good current of warm, dry air about the bunches by removing two panes of glass from the front ventilator opposite these Grapes. On very warm days these were taken out, in addition to the usual ventilation given, the result being berries coloured to perfection, and no cracking

occurred. I followed this treatment this season also, with a like result.

Lateral growth is encouraged on all the Vines, pinching them occasionally during full growth. On an Alicante Vine this year one shoot produced a bunch at the point of it, no growth whatever being made beyond it. As a curiosity it was left to develop. Five leaves are on the branch between the rod and the bunch, which is of extra good shape, berries of same size as the others, colour also the same. The bunch weighs about 6 lbs. I find that Muscats especially, where lateral growth is allowed, require a greater quantity of water than when stopped close to the bunch, otherwise shrivelling occurs. In the case of Muscats, and Madresfield Court in particular, I shall continue to allow a little lateral growth until I am dissatisfied with the results.

I have heard some say, "Why permit lateral growth and then have to cut it away again? It is pure waste and harmful." Undoubtedly it is if they grow unchecked and form a thicket excluding both light and air from the main leaves; but from my experience with both young and old Vines I have not yet found any evil effects from the practice, but rather benefit if moderation be the rule.

This discussion between Mr. Dunkin and Mr. Iggulden is a most valuable one, and gardeners who have not had much experience in Vine culture will find it difficult to decide which to follow, so ably do both defend their practice and teaching. Therefore I would say studiously read both.—GEO. GARNER, *Amberwood, Christchurch.*

No doubt it would be interesting to many of your readers to know whether the heavy crop of Grapes per Vine recorded by Mr. Dunkin in your last issue are Vines with more than one rod, and what length they are. This is an exceptional weight, for Hamburgs especially, to carry, and this without the aid of stimulants, for in my experience this Grape above all others resents heavy cropping in the prospect of a good finish.

Having spent a few years in a well-known establishment near the metropolis, I am well aware that market growers go in for extraordinary crops; but they work upon entirely different lines to private growers, and how long does the practice last? I for one should like to hear something about the general management to insure such fine crops of Grapes. I must confess I am a long way behind the times. Some districts no doubt are admirably suited to the requirements of various kinds of Grapes, which is of material consequence in bringing a heavy crop to a good finish, combined with a good spread of foliage and good management. I agree with Mr. Dunkin that a moderate extension of growth is one of the best methods for keeping up the stamina of the Vine for a long period. I think stopping at the bunch too sharp practice, especially if the leaves get damaged in any way, for by the time fresh growth starts it is getting late in the day to be of much service in perfecting the fruit.

This "something" in the way of colouring black Grapes, too, would be highly instructive, for, judging from the moderately finished examples we see on the average in our travels, it cannot be quite so simple as it at first appears. Grapes good enough for home consumption are produced in quantity, but they are a very long way from a first-class standard of excellence, judging from what we see staged at many of our leading horticultural exhibitions and elsewhere.—J. J. C.

[We have other communications on this subject for which space cannot be found this week.]

FRUIT GLEANINGS FROM CRAWLEY.

FROM the time that opening spring begins to tinge the trees with green until the ruddy glows of autumn stain their foliage, Crawley has attractions which merit a frequent pilgrimage. The quiet little town has a charm of its own, and its surroundings do not become less pleasant as they are familiarised by frequent observation. Visitors to whom pedestrianism is a wholesome enjoyment and not a terror, might alight at Horley if their goal be the great nursery of Messrs. Cheal and Sons at Lowfield Heath. The road winds pleasantly from the little country station into the main thoroughfare to Brighton opposite a church which stands in a beautiful setting of flower-furnished resting-places—a true "garden of sleep." A few miles away on the right lie the range of uplands which stretch away from Redhill and Reigate

towards the west, bold and beautiful in the distance, and full of delights if wandered amongst in the freshness of an October morning. Farther on, however, an almost right angular bend of the road turns the visitor towards Crawley and Brighton, and the hills of Surrey are left behind. The thoroughfare pursues a pleasant but hardly gardenesque course until the long lines of Conifers and fruit trees on the right betray the location of the Lowfield nurseries, even before the board signifying their existence there becomes discernible. A sign-post near Horley station tells you that the distance to Crawley is five miles, but two out of the five may be deducted if a call at Cheal's is in view, for the nurseries are that distance on the London side of Crawley, and, as a matter of fact, they are within the borders of Surrey.

Few plant homes present a more pleasing view to the wayfarer than that at Lowfield. It grows upon him from the first, and as it stretches along by the side of the road for a mile or more, with fresh trees, shrubs, and flowers opening upon the view at every stride, and culminates in a broad flower-lined drive, ablaze with colour from spring to autumn, with handsome foliage plants on left and right, it presents a picture such as arouses the interest and sympathy of every visitor. Its aspects are changing, of course. He who passes it week by week, as spring deepens into summer and summer mellows into autumn, anon in the freshness of early morning and again in the cool hush of eventide, will best realise its changeful features; but its charm is perennial if the material composing it be varying and diversified. A pleasant old house

FIG. 50.—APPLE THE PROFESSOR.

embowered in creepers and skirted by lawn and borders, stands on the right. There resides the venerable father of the enterprising Joseph and Alexander Cheal, the well-known partners in the firm. Though his life spans two centuries, his hair being silvered by the snows of ninety-two winters, his physical vigour is by no means exhausted, and his intellect is keen and clear. I recently heard of him wishing to dismount from a trap to pick up the fallen umbrella of a visitor, who, though bearing the honours of a long life's work for horticulture, is still many years his junior. Pure air, plain food, and hard work are the three principles which have dominated the life of Mr. Cheal, senior. They are potent antidotes to the evils that beset humanity.

CORDON PEARS.

One of the most striking sights at Crawley is the house of cordon Pears which was referred to in late spring as presenting a very promising appearance. The present being a very bad Pear year its condition when inspected a fortnight ago was the more impressive. Trees well furnished with handsome fruit bespoke the advantages of this method of Pear cultivation, which practically sets frost at defiance. General Todleben was carrying a crop of grand fruits. Bon Vicar is a September and October variety, very prolific and useful. Belle de Brussels, a Bergamot-like fruit and a good bearer, is promising. Thompson's, which is well known, was fruiting well. It is unexcelled amongst November Pears for sweetness; indeed, is too sugary to be perfect in flavour. Duchesse de Mouchy is a late variety that will perhaps become popular, being a free bearer of very large fruit. Beurré Sterckmans was carrying a very heavy crop of fruit, and this

excellent variety might with advantage be more generally grown. One of the best Pears in the house was Princess, a seedling from Louise Bonne of Jersey, raised by Mr. Rivers. It is remarkable for its fine constitution, free growth, and abundant crop of attractive fruit, which is coloured, like that of Louise Bonne, on the sun side. Princess is a valuable November Pear, and may be highly recommended. An older Pear that is doing well and is worth more extended culture is Zephirin Grégoire. It is ripe in February, is hardy, prolific, a heavy cropper, and of good flavour, admirable as a bush, as a cordon, and in fact in all forms. These are but a few of the varieties. The trees are in splendid health, as also are those out of doors; indeed, cordon culture at Crawley is a feature of the greatest interest. The trees are trained upon all manner of supports—walls, fences, arches, and others—and the routine of management is of the simplest character. This form of fruit tree is growing in popularity, as affording means of cultivating a considerable number of varieties in a comparatively limited space.

BISMARCKS FOR GERMANY.

Leaving the Pears and coming to the Apples, we have more proof of the growing popularity of Bismarck. It may be of interest to note that large orders are being received for it from Germany, where it is in great demand. This may perhaps be taken as another indication that the once all-powerful German Chancellor has not yet lost his hold upon the people, for doubtless the name of the Apple has much to do with the demand for it in the "Vaterland." When they get it they will find that there is more than a name in it, however, and it will not be surprising if some of the German market growers become a little divided in their affection for the variety, one leaning to it being brought about by patriotism and the other by profit. It is to be feared that the latter will eventually triumph, for the Apple will live long after the man of blood and iron is no more. Bismarck is a grand Apple for all-round merit without a doubt, and the high praise of Messrs. Cheal's foreman that it is in every respect as fine an Apple as Lane's Prince Albert, while likely to form a better standard, is significant.

THE PROFESSOR.

The Professor is an Apple that Messrs. Cheal grow remarkably well, and as it is comparatively little known an illustration is given of it (fig. 50). It is handsome, and the tree is a free bearer. The fruit is medium sized, round, and a little depressed; $3\frac{1}{4}$ inches wide and $2\frac{1}{4}$ inches high; bluntly angular. Skin smooth and unctuous to the touch, lemon yellow, and without any trace of colour. Eye with divergent segments, rather large, and set in a considerable depression, somewhat angular; tube funnel-shaped, stamens median. Stalk quite short, inserted all its length in a close cavity. Flesh quite white, unusually tender, juicy, and with a pleasant rather tart flavour. Cells obovate axile. A remarkably fine early cooking Apple in use in September.

A TRIUMPH IN FRUIT GROWING.

The Crawley firm's success in fruit growing, and it will be conceded that they have forced their way into the front rank, is a record of triumph over difficulties which would have deterred many even from a trial. A great part of their soil is heavy and tenacious clay. I believe the land was originally a common, but good cultivation has worked wonders with it. There are scores of acres furnished with healthy, thriving trees, not with the soft, succulent appearance of luxuriance and immaturity, but stiff, hard, and firm. They have had to fight their way, and considering everything their progress has been remarkable. There would be no fear of retrogression with such trees; indeed, if placed in better soil, their hardy constitution and strong foundation would insure a bright and useful career. Of the quality of the fruit they produce Messrs. Cheal have given many striking proofs of late. For a time they failed to get such large, clean, and well-coloured examples as those in more favoured spots, but the sheltering hedges have now got up to a sufficient altitude to serve their purpose, the soil has been improved, and so we find the Crawley fruit earlier, finer, cleaner, and richer than before, and well able to contend with that from other localities. It is an achievement to be proud of, and the reputation of the firm will grow as it becomes better known how hard they have had to strive for it.

Apples are grown on an enormous scale. The Queen, worked on the English Paradise, grows freely, and gives handsome fruit. American Mother, with its soft, tender flesh of delicious flavour, and its free-growing character, is conspicuously good. It is a splendid dessert Apple. Golden Spire does extremely well, bearing very freely, and holding its fruit for several weeks. The Forge, a well-known Sussex Apple, is fruiting abundantly. It has hardly any stalk, the fruit appearing to push directly from the spur, and consequently rough winds are powerless to affect it. Beauty of Kent has been cropping heavily, and has developed fine colour. Lady Henniker has proved its usefulness by carrying a heavy burden of fruit. Baumann's Red Winter Reinette, a good Apple, with far too long a name, has proved to be hardy and useful in every way, giving satisfactory yields of its attractive fruit. Landsberger Reinette is an Apple not very often met with, but it has proved very good indeed at Crawley, being an immense bearer, and suitable for either dessert or cooking. It will probably be found to make an excellent cordon. The sweet and attractive little Apple Jefferson, with its neat striped fruit, is worthy of a note. Of all the Apples at Crawley none gives greater promise than Newton Wonder, which is making its mark as a fine late variety. It bears heavily in a young state. The fruit has the open eye of Wellington. The texture is firm, and it is an excellent keeper. Now that planting-time is at hand the merits of this really good late Apple should have due consideration. It

would be impossible to mention every variety that has carried a good crop in the Lowfield Nurseries this year, but besides those mentioned Betty Geeson, Cox's Orange Pippin, and Annie Elizabeth may be noted. The character of Betty Geeson there and elsewhere makes one wonder that it is not more frequently met with. There is a faint reminder of Bramley's Seedling in the fruit, although the two are quite distinct, but Betty is superior in bearing well in a young state on the Paradise. On the heavy soil at Crawley Bramley's, grand Apple though it is, will not do that.

GENERAL FEATURES.

Messrs. Cheal & Sons deal so largely in trees and shrubs that a passing reference ought to be made to this feature of their large and extending business. All the popular kinds and varieties are to be observed in the same excellent condition as the fruit trees, being strong, clean, and healthy. Seeing the Crabs as they are grown at Crawley a good lesson is learned of their great value as ornamental trees. The Dartmouth, with its load of rich deep red fruits, was particularly effective. Fairy, red and yellow, also presented a charming appearance, as did the red and yellow Siberians, John Downie, and Transcendent. These trees are well worth growing for autumn effect. The Dahlias had, unfortunately, just been blackened by a sharp frost or two. The Tom Thumbs, with their compact growth and abundant flowers, must have been very beautiful. They have given a striking proof of the extent to which improvement may take place in plants after recovering from the effects of early hard propagation, and now form an extremely useful class. Some plants towards the front of a shrubbery border in a small garden this autumn have been as beautiful as any Begonias. It would be worth the while of anyone who may have been a little disappointed with them at first to try them again now that time has given them more stamina. Under glass everything was in good order. Time will not permit of details, but the large stock of Climbing Niphetos Rose was very noticeable. The demand for this valuable variety grows rapidly, and it looks like becoming as popular as its beautiful and valued parent. Messrs. Cheal have abundance of healthy plants. Rhododendrons in course of grafting also made a brave show, the number propagated being enormous. Doubtless they are utilised largely in an important feature of the firm's business—namely, garden-making and landscape gardening. Many beautiful places in Surrey, Sussex, and other counties owe their effectiveness to the plans and material supplied by the Crawley firm. That all branches of their business should grow is but the just reward of labour, for they have striven unceasingly for excellence, and have played no unimportant part in advancing British horticulture.—W. P. W.

TRICHOSMA SUAVIS.

WHEN Dr. Lindley first saw this plant he considered it to be a *Coelogyne*, but after further examination he placed it in a new genus, of which it is at present the only species. *T. suavis* was discovered and sent home by Mr. Gibson, a collector for the Duke of Devonshire, in 1840. It was found growing on the trees in the dense forests which prevail at considerable elevations on the Khasia Hills. The stems are slender, from 6 to 10 inches high, bearing a pair of bright green ovate lanceolate leaves; the racemes rise from between the leaves and bear six or more flowers each over an inch across; the sepals and petals are creamy white, the three-lobed lip has white lateral lobes striped with crimson, centre lobe recurved, yellow and brown with crimson edge, disc crisped.

This plant deserves to be more widely cultivated than is at present the case, and the beautifully scented flowers add to its value; it blooms during October and November. *Trichosma suavis* ought to be potted in peat and sphagnum, and requires a free drainage, as it should have plenty of water while growing, and when growth has ceased it must not be allowed to become dry. It is admirably adapted for cool house cultivation, although imported or weak plants should be placed in an intermediate temperature until well established.—C. K.

ORCHIDS IN BLOOM AT CHELSEA.

FOR Orchids the present is perhaps the worst time of the year for seeing flowers, especially in London, where the smoke unfortunately plays early havoc with these chaste and lovely blooms. But it would, I imagine, be a most difficult matter to walk through the magnificent range of Orchid houses at Chelsea without finding a great number of the plants bearing flowers. The *Cypripediums* are very fine, the most striking varieties noted in a rapid walk through the houses being *Arthurianum*, *Spicerianum*, *albo-purpureum*, *Cleola*, a magnificent almost pure white flower; *Chamberlainianum*, and *T. B. Haywood*. The latter is one of the most effective now in bloom. A grand piece of *Dendrobium*

Dearei looked magnificent, although it has been in flower for nearly three months. Among other Dendrobiums in bloom I noticed *formosum giganteum*, *Statterianum*, and *Schœderi*. *Vanda Kimballiana* is a most charming Orchid, as also is *Aërides suavisimum*, the specimen now in bloom being magnificent. In another house were good examples of *Oncidium ornithorhynchum*, very sweet scented; *tigrinum*, *flexuosum*, and *varicosum*; *Maxillaria grandiflora*; *Sobralia macrantha* and *xantholeuca*; *Cymbidium giganteum*, *Epidendrum dichotomum*, and a few *Cattleyas* in variety.—H. W.

LÆLIA PERRINI.

THE unfolding of the flowers of this fine old autumn-flowering *Lælia* is evidence of its value at this season of the year. True, there is not such a dearth of autumn-blooming Orchids now as formerly, but its freedom of growth and also flowering propensities rank *Lælia Perrini* upon a decorative point of view as one of the finest Orchids in cultivation. The white flowering variety is unique, and happy must be the possessors of it; but as the majority of us should be thankful or content with the normal form, we can look upon the other as a beautiful vision. I have three plants, and each season they advance in size and also the number of flowers, as this year the aggregate number of blooms for the three plants is twenty. Its natural habitat is said to be on the northern slopes of the Organ Mountains, which suggests comparatively cool treatment. Our plants thrive well in the *Cattleya* house, and are growing in teak baskets, the material about the roots being good fibrous peat with a little sphagnum. Whilst in full growth it takes a good supply of water, and even after flowering throughout the winter it must not be kept too dry or else its thin pseudo-bulbs will shrink, and which is not advisable.—A. YOUNG.

EDUCATION IN GARDENING.

(SILVER MEDAL ESSAY, continued from page 347.)

METHODS TO PURSUE.

IN addition to the widespread educational facilities previously mentioned, the South Kensington Science and Art Department provides, either before a lad leaves school or after for the necessary, unbroken continuity of a steadily advancing education from the elementary stages in scientific and other subjects, onward to and including the advanced stages, which may be taken advantage of by all local educational agencies. In some outlying districts this source may fail, and the student must then fall back on his own resources. Perhaps he may be able to join with others in forming a class for their mutual improvement supplemented by the help of the village schoolmaster, &c. Under these circumstances he would do well to take advantage of a change of situation, when circumstances were favourable, for one within reach of the necessary educational facilities.

It is evident that much will depend upon the educational opportunities and the rate of progress made during the early stages of the gardener's career, as to the course of study and reading to adopt. If so circumstanced as to be under the necessity of taking some or all of the elementary sciences after he has entered on his novitiate in a garden, it becomes a matter to decide whether he is able to take up more than one subject at a time; capacity to receive instruction, and time at command, will determine this point. It would be better, however, to do one thoroughly than attempt two and fail. Always keeping in view that the gardener's education must necessarily be a progressive one, extending to a later period in life than that of many others, no hard and fast line can be drawn regulating the time for study. In summer it is wise never to relax efforts entirely, but winter is the season for the supreme effort. If the student gave from two to three hours per night during four nights per week, the following would not prove a bad arrangement: Scientific subjects, Garden literature, Garden periodicals, general literature—one night each. This would leave sufficient spare time for recreation, or any sensible hobby which the inclination of the individual suggests.

The results of the young gardener's practical training will in some measure depend upon the extent and management of the establishment where he is employed, and the opportunities placed in his way. On the other hand more will depend upon the cultivation of his innate abilities, perseverance, and adaptability to circumstances, to his readiness in grasping the lessons which his scientific knowledge teaches, and assimilating it with the best results coming under his observation. At all times he must bear in mind that his wages are paid for efficient services rendered as a practical workman. His first duty to his employer and himself, therefore, is to acquire proficiency in the use of all garden tools, and to learn to perform all the needful operations in a workman-like and expeditious manner. To this end a thorough liking for

his work is necessary, combined with close observations of methods, finish, and quantity of work done by experienced workmen. Concurrently with the dexterous use of his tools he should develop the faculty of intelligently grasping all the details of his work. A good workman before he begins an operation can see it mirrored in his mind's eye as it should be when finished. This faculty prompts him to carry out the details in their proper sequence, so that no part need be twice done. Every simple garden operation requires this forethought until it becomes habitual, and no gardener worth the name will rest content until he has attained equality with the best workmen.

Having in due course dealt with the elementary "specific subjects," a systematic advanced study of them must still be continued, combining with them the purely practical into one homogeneous whole. The student before reaching this point will understand and appreciate that the gardener's education is a dual combination of skilled workmanship, and the important lessons which his ever advancing studies teach him as bearing and being dovetailed into his everyday work. The workman who possesses this knowledge and combines with it a study of methods, and the results accruing from them is accumulating sound practical knowledge of the highest order, at the same time transforming what otherwise would be objectless taskwork into interesting occupation.

A diary should be kept of all important garden operations, seed-sowing, potting, planting, dates of starting, forcing houses, &c., their day and night temperature, dates of fruit and other crops ripening, with notes and observations on data gathered. The daily readings of the barometer and thermometer, the accumulated temperature worked out; if possible the sunshine record taken on the lines carried out at the Regent's Park Botanic Gardens, observations of hardy plants and trees leafing and blossoming, first flowers opening, and first leaf surface visible, fruit ripening, and the beginning of natural defoliation, are all advantageous to the young gardener. A regularly kept diary of this description might be made into a reliable standard of the climatic conditions affecting the vegetation of the locality where kept. One section of observation could be used to check the other, and thus discrepancies would be reduced to a minimum, serving as a valuable guide as to the hardiness and earliness of plants and crops, the most suitable time to sow and plant them, and other data bearing on productiveness and suitability to position. To lessen individual work of this description different branches might be allocated, and an individual and collective summary made where several gardeners are kept.

Visiting horticultural exhibitions, good garden establishments, botanic gardens, public parks and nurseries, is of so great utility that every opportunity should be taken to do so. Useful lessons in degree of culture, methods, economy of labour, plant and tree nomenclature, arrangement of colours, and general effect in flower gardening may be thus acquired, besides opening out extended fields of observation on cultivation and general management. The interchange of opinions on both successes and failures are also important factors in ripening the judgment and promoting sound useful knowledge.

Colleges or schools of horticulture may be considered to be in the experimental stage. Amongst others which space forbids reference to, there is one point which must militate against their permanent success as purely educational agencies for general gardeners. The cost of a two or three years' course would generally prove to be a bar, amounting in time and money to a larger sum than the prospects of a paying return would justify. The well paid appointments are too few, even where the cost could be afforded, to risk a livelihood upon. On the other hand, the general gardener by self education and supplementary aids thereto, is adopting means to improve his position, which of itself is a powerful incentive to success, whilst it remains to be proved that those who possess wealth to be able to take advantage of this means of high-class teaching would be the class of men who could hold their own position, or compete all round with those who under educational drawbacks have made British horticulture what it is to-day.

Gardeners' improvement societies have become recognised educational agencies. When properly managed, they furnish their members with opportunities for discussing details of culture and getting directly to the root of any cultural question they are seeking information upon. Writers of "essays," although supposed in this respect to be the teachers, receive the greatest educational benefit of anyone concerned. The discussions impart confidence and discrimination in speaking, thereby improving the address in ordinary conversation. The library facilities give opportunities of consulting books which are beyond the power of purchase by individual members. The general usefulness and value of these societies will largely increase as the education tide rolls onward; a greater proportion of the members will be able to take part in the

discussions, speaking with the increased authority and confidence which education carries with it.

The gardening Press in a general way covers the whole field of horticulture, and from this point of view is the greatest educational agency we possess. At prices within the reach of all, we are kept abreast of all matters in connection with the "craft," by the best practical men of the day, who know well that their teachings must be sound, or woe betide them. The lynx-eyed critic is at all times on the alert to discover the weak point in their armour, and any controversial question arising gets well threshed out, so the general reader reaps the benefit; the editorial supervision winnows the chaff from the grain, and condenses into a reasonable compass pabulum suitable for all degrees of gardeners. Thus week by week we have to hand an invaluable gardeners' educational agency, which has led the van in horticultural progress. In the new educational era upon which we are now entering we have hope and faith that it will still continue to do so, but the young gardener must understand that as the only source of instruction it would not suffice, by reason of what may be termed its non-continuity. It is in this direction that the extreme value and utility of good books is made evident.—T. GARNETT.

(To be continued.)

MONTBRETIAS.

ON noticing Mr. Wolley Dod's note on these flowers in last week's Journal, and the difficulty experienced by some growers in saving them during severe winters, it may not generally be known that the bulbs can be lifted—say, early in November—and dried off in the same way as Gladioli, Tigridias, and similar late-blooming bulbous plants. They should be kept cool and dry (out of the reach of severe frost), and be planted again about the end of February or early March, as weather permits. When lifted it is important that all stems and foliage be cut clean away at the time of taking up, otherwise the bulbs are apt to shrivel; and secondly, not to cut the stems nearer than about an inch from the crown of the bulb, as the lower part of the stem sheaths the main embryo eyes for the following year's growth and bloom.

The yellow varieties, such as Aurea and Gerbe d'Or, appear to be much more tender than the reddish-coloured varieties. All the former left in the ground during the past two severe winters were killed, while patches of the typical red crocosmæflora has had a continued existence as a hardy plant here, without any protection, and has withstood frost within a few degrees of zero.

We have found the flowers and spikes from the dried bulbs to be much larger and finer than from those left in the ground all the winter, and to bloom quite as early, each full-sized bulb sending up three or four strong main stems, with large spikes of flowers to each. Pottsi is a very hardy variety, but its shyness of blooming compared with the other varieties is much against it, though possibly the drying-off process and replanting the detached, full-sized bulbs might be the means of greatly improving it in this respect, but we have never put this to the test.

The plan described for the Montbretias we find answers equally well for Gladioli of the purpureo-auratus type (Lemoinei hybrids), of which so many complaints are made of their doubtful hardiness when left in the ground all the winter. Some of these lifted last November, dried off, and not replanted until April, have bloomed exceedingly well, and the new bulbs in finer condition than when left in the ground all winter with protection.

Gladioli and Montbretias are such fine autumn flowers, their bright colours contrast to the pale hued Michaelmas Daisies blooming at the same time, and long after the first slight frost of autumn has marred the beauty of Dahlias, that I am tempted to send these few notes, hoping they may be of service to those who have hitherto experienced difficulties in cultivating these plants.—J. BURRELL, *Cambridge*.

DISCUSSION ON APPLES.

THE INFLUENCE OF SOIL.

IN a note on Apples, page 257, allusion is made to Frogmore Prolific, and it is questioned as to whether the soil or the stock is the cause of variation in the manner in which this Apple crops and succeeds in different places. This remark applies not only to Frogmore Prolific, but to many others. My opinion is that the soil is much more to blame than the stock for such wide variations in the manner in which varieties behave in different localities. In some soils, generally those that are heavy and retentive, and consequently colder in winter and spring, we find certain sorts will barely exist, to say nothing of giving a full crop of fruit, while in another place where the soil is contrary in its component

parts we find the same sorts heavily laden with fruit. In my experience I cannot call to mind a single instance where the same kinds of Apples have been planted in the ordinary way on soil similar in character that have exhibited any change in their manner of progress. I mean one that has succeeded while the same sort in a similar soil has failed.

I am strengthened in my conviction that it is the soil which has to do with the success or otherwise of certain varieties by experiments made during the present year in the method of planting certain sorts. I have trees of the same sort growing under various conditions, and can plainly notice a difference in the manner in which they behave. Two trees of Schoolmaster exhibit a marked difference in their fruit. One tree is planted in the ordinary way, the soil not raised above the surrounding level; some of the fruit on this tree are cracked, covered with specks, and otherwise disfigured; the foliage is also pale in colour. Tree No. 2 is growing on an elevated mound, 15 inches at least above the surrounding ground level; much of the extra soil is decayed vegetable refuse and leaf mould. The fruit borne by this tree is absolutely without speck or crack, and the foliage is of a dark green colour—the picture of health. I have many varieties growing on these mounds, and promising they look. It will be necessary to add more soil or decayed refuse yearly for the roots to run into, so as to encourage them to remain in the best position—close to the surface. Why I consider these mounds beneficial to some sorts is that the soil in which the roots are must be warmer at all times of the year, and certainly drier than though it were mainly below the ground level. Of course this method of planting entails more labour in the matter of mulching and watering during dry weather in summer, but if by this extra outlay we are enabled to cultivate sorts otherwise a failure the extra trouble will be of small moment.

One too often reads that certain varieties should be planted owing to their good qualities, but such advice is very often unaccompanied by the assurance gained from a practical knowledge that the same sorts will flourish in any soil. This I consider a very fallacious manner of giving advice. If persons would say if the same sorts will succeed in all soils, then the advice would be more reliable.

LORD GROSVENOR.

This is undoubtedly a grand kitchen Apple for early use. Where Lord Suffield does not succeed, and there are many such instances, this sort should be planted. Here Lord Suffield has been a failure for many years until this season, when it has given us abundance of fruit. Why this has been so I do not know, unless it was the dry weather experienced during May, which certainly favoured the setting of the fruit. In our soil the trees make such little growth that many of the shoots made during the summer die the following winter. In this respect Lord Grosvenor differs very much, appearing to be hardier in constitution and more fitted to plant in our heavy cold soil. Lord Suffield succeeds admirably in the lighter soil overlaying the red sandstone rock north and east of Liverpool. There it is a great favourite, and deservedly so; nothing could excel the crops of fruit I have seen there of it. Perhaps Lord Grosvenor is the most profitable early kitchen Apple we have. The fruit is ready for the market the first week in August, and good prices are then realised. Lord Grosvenor needs but little attention in pruning. The growth is short-jointed, rather erect, which is a point in its favour where a quantity of trees are to be planted on a small space. This variety is not averse to a liberal supply of stimulative food in the shape of liquid manure and mulchings of partly decayed horse droppings for heavy land, and that from the cow house in the case of light sandy soil.

EMPEROR ALEXANDER.

This is one of the shy bearing sorts in the garden here, although the growth is fairly good. Its barrenness cannot be caused through want of root-pruning or restriction of its branches, because the tree has had plenty of both. I attribute its almost sterile condition to some chemical element contained in the soil to which it objects. In a garden not more than a mile from here this variety trained as an espalier bears annually full crops of highly coloured fruit. The soil in that garden is much lighter in texture than is this, consequent upon the presence of so much chalk, both near the surface and impregnated with it.—E. MOLYNEUX, *Swanmore, Hants*.

FIVE CROWN OR LONDON PIPPIN.

THIS variety is growing in a cottage garden near me, and it has not failed to give a full crop the last ten years to my knowledge. It is a kind of a bush-formed tree, the lower part having some large limbs, the smaller branches being cut off to make head room. The tree is planted in the middle of a hedge, by which a path runs. It is an excellent cooking Apple. Its name is

taken from the shape of the fruit, the ribs forming at the top a crown of five parts.—YORKSHIREMAN.

NELSON CODLIN.

THIS is a sweet variety of good size, greenish yellow when ripe, and a fairly good cropping sort. The tree is of dwarf habit, not unlike Keswick Codlin in this respect, and, though subject to canker, it is on the whole a useful sort. It is not exactly an early variety, as the fruit keeps in capital condition till February.

KING OF THE PIPPINS.

This Apple has in certain quarters been so much depreciated that there may be some hesitation to grow it. As a dessert fruit it is not equal to such as Cox's Orange, but there are dessert sorts which are not one whit better as regards flavour. The tree possesses a healthy constitution and a dwarf habit of growth. The fruit is not large, but if the crop is thinned early in the season the Apples will swell considerably. As a cooking Apple, King of the Pippins is well worthy of attention, and in soils where it does not develop a dessert flavour it will be found to be one of the most useful for the kitchen. I allow the fruit to hang late, and gather it as it becomes ready.

COX'S POMONA.

This is a very pretty well-flavoured Apple, which may be employed in the kitchen or occasionally for dessert. The tree is of medium spreading growth, which cankers rather badly with me. Young trees produce very handsome fruit. Though a soft Apple the fruit must be allowed to hang late in order to develop its flavour.

WARNER'S KING.

This may be designated the Apple of many aliases. Most gardens possess it under more than one name, and not a few nurserymen catalogue it under a variety of designations. I knew it first as Hawick King, and then as Nelson's Glory. It is extensively cultivated as D. T. Fish. I have also seen it under the name of Barker's Seedling and Cobbett's Fall. It is a very distinct Apple, and is quite easy to determine.

KESWICK CODLIN.

I see that this old favourite does not give universal satisfaction, but according to my experience it deserves a place in the front rank of culinary Apples. Under the treatment I have for many years given it I could desire nothing better. We begin to use the small fruit after Early Julyan is past, and later on the largest fruits are removed, allowing the others to remain, when they swell to a good size. As a jelly Apple Keswick Codlin is first-rate. It seems to do best on a system of spur-pruning, and it is necessary to remove all small spurs which appear incapable of bearing fruit. Some old trees which have nothing but small spotted fruits were completely rejuvenated by the simple process of thinning out the many spurs with fruitless buds. Aged trees I would boldly decapitate, and expect in three to four years to have a fair crop of beautiful fruit.

APPLES AND LIGHT SOIL.

It is due to Mr. Raillem to state that the light soil I referred to is not of a loamy nature. The class of soil quoted in his note I should consider just medium for Apples of all sorts; and, indeed, for all kinds of fruits. I can assure Mr. Raillem that Lord Suffield, Cellini, Stirling Castle, Blenheim Orange, Dumelow's Seedling, and Tower of Glamis, all of which are first-rate sorts, cannot be depended on when grown in light soils. The trees do not thrive, some do not bear freely, and the fruit is deficient in size and quality. On the other hand, I have seen each of them doing splendidly on heavy soils; in some cases approaching to clay.—R. P. BROTHERSTON.

BEAUTY OF HANTS.

I DRAW attention to this Apple once more to refer to the very remarkable results found in the drying experiments conducted at Chiswick, and reported in the *Journal* last week. Here we find such solidity or firmness of flesh that the dried yield is 6 ozs. from 10 lbs. of fruit in excess of that obtained from Blenheim Pippin, so that here is conclusive evidence, were any needed, that the varieties are dissimilar; 6 ozs. excess may not seem much on 10 lbs. of fruit, but were the quantity 100 lbs., and the same proportion of dried product maintained, their increase would be 5 lbs.—a very material quantity, and making an immense difference in a profitable aspect were the amount dried product from a ton of Apples. It is interesting to note that whilst the popular Lord Suffield gives only 1 lb. 2 ozs., the Beauty of Hants gives exactly double the quantity of dried product from 10 lbs. How that fact illustrates the difference there is between the texture of many varieties, for the biggest is not always the best.—A. D.

COLOUR IN APPLES.

MR. MOLYNEUX almost beat the record in the very beautiful colour he has been able to induce *Mère de Ménéage* to put on at Swanmore Park; and his Cox's Orange Pippin, showed with these at the Drill Hall the other day, were also remarkable for high colour. But it was a striking fact, yet perhaps borne out by most Apple growers' experience, that the very high colour left something to be desired in flavour, as that was not so good in the Swanmore fruits as in those devoid of colour from Hastings. Whilst it is no guarantee that a rough or russety skin is allied to flavour, yet it is a fact that great beauty and high colour afford no indication of the presence of flavour also; indeed, we have hardly a rich-coloured variety in cultivation that can at all approach in flavour to Ribston, Cox's Orange, and other dull coated Pippins, such as the Cockle's, or of some of the Russets, or Margil, or of many others that could be named. Colour always tells well with judges of exhibition dessert fruits, but were these tasted it is probable that they would lose in flavour what they gain in colour, hence dull coloured fruits should be tested for flavour when found in competitions.—A. D.

EVENTS OF THE WEEK.—Horticultural events will be numerous during the ensuing week. On Tuesday, November 1st, the Committees of the Royal Horticultural Society will meet at the Drill Hall, Westminster, particulars of which are given elsewhere. The annual Exhibition of the Kent County Chrysanthemum Society will open at Blackheath on the same day, as also will one at Brixton. Croydon Chrysanthemum Show opens on Wednesday, November 2nd, as likewise do Portsmouth, Guildford, and numerous other Exhibitions. A list of some of the leading Shows will be found on another page. Several sales will take place at the various auction rooms.

— THE WEATHER IN LONDON.—During the past week the weather in the metropolis has been of a variable character. Sunday was bright but cold, with a frost at night, similar weather continuing on the following day. Tuesday proved dull with occasional showers but a sharp frost occurred at night. At the time of going to press the weather is bright and seasonable, the wind being in a north-easterly direction.

— ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Society will be held as usual in the Drill Hall, Westminster, on Tuesday next, November 1st. At 3 o'clock in the afternoon a paper on "Fruit Trees in Pots" will be read by the Rev. W. Wilks, M.A., Secretary of the Society. Among the exhibits Chrysanthemums will doubtless form a conspicuous item, especially as the Council have offered prizes for competition in three different classes. Growers wishing to enter the lists should communicate with the Superintendent of the Show as to space, &c.

— GARDENERS' ROYAL BENEVOLENT INSTITUTION.—Intending candidates for the next election of pensioners on the funds of this Institution should at once apply for the necessary forms of application, which must be returned to the Secretary on or before November 25th next, after which date they cannot be received.—GEORGE J. INGRAM, Secretary. Office, 50, Parliament Street, London, S.W.

— THE FRUITERERS' COMPANY AND THE LORD MAYOR.—At the Court of the Company, held on the 18th inst., the following resolution was passed unanimously:—"That the cordial thanks of this Court be presented to the Right Honourable the Lord Mayor (Sir David Evans, Bart.) for his courteous and generous hospitality at the Mansion House to the members of the Court and their ladies on the 12th inst., and they desire to place on record their belief that such occasions have a distinct influence in the promotion of the objects of the Company, which include the more extended cultivation of hardy fruit in the British Isles."

— FRUIT AND THE LORD MAYOR'S SHOW.—In reference to our intimation last week we are able to announce that active steps are being taken by the Fruiterers' Company in having a representation of home-grown fruit in the historical procession on Wednesday, November 9th. The Committee appointed to carry out this project

consists of the Master of the Company, G. J. Brocklesby, Esq.; the Upper Warden, Henry Martin, Esq.; Renter Warden, the Chevalier Sperati; Past Masters, Sir James Whitehead, Bart., M.P., and H. R. Williams, Esq., with the following Liverymen—Messrs. G. Bunyard, J. Cheal, A. H. Smce, J. Wright, and Mr. John Eagleton, Clerk of the Company. At a meeting held in the Guildhall on Monday last the general design of the trophy was decided upon, and the offer of Messrs. Bunyard and Cheal to supply fruit was accepted. The fruit car is to be prepared at Maidstone, and the details of furnishing carried out by Mr. Bunyard, Mr. Cheal giving his willing co-operation. This representation will bring fruit before the million in a way in which it has never been brought before, as no crowds equal in number those of the Lord Mayor's Show, for the densely packed sight-seers extend for miles.

— CHISWICK GARDENS.—The Michaelmas Daisies, which for a long time past has been one of the chief floral features in the Gardens of the Royal Horticultural Society at Chiswick, have now practically finished flowering for this year. Their place, however, has been filled by the large collection of Chrysanthemums, which have been moved into the large conservatory. The plants are in a fine healthy condition, and will soon be a mass of flower worth seeing during the winter months.

— A NEW CANNA.—An American contemporary states that a gardener in the United States has raised a Canna which is said to be an improvement on Madame Crozy. It is reported to have a golden band a quarter of an inch wide around the petals instead of the narrow yellow margin, as in the above named variety.

— A DOUBLE-FLOWED MUSK.—Last year, says an exchange, one or two well-known firms obtained a supply of a new double-flowed Musk. It came as a novelty from Germany, and is found to do admirably in pots. The small, double, sulphur-coloured flowers are produced from every joint, and the pronounced Musk-like odour from the leaves and flowers is very powerful, a single plant being sufficient to scent a whole room.

— PRESENTATION TO MR. J. ROSE.—In giving up the charge of the gardens at Lockinge House, Wantage, recently, Mr. J. Rose was presented with a handsome silver biscuit box by Lord and Lady Wantage. The under gardeners also gave him a marble clock; the upper servants at Lockinge a dozen silver teaspoons and a pair of sugar-tongs; and the members of the cricket club a cruet stand. Mr. Rose has now gone as head gardener at Wokefield Park, Reading.

— HELENIUM AUTUMNALE.—This North American hardy perennial plant should be grown in every garden in which herbaceous plants find a place. The branching stems spring from a compact tufted rootstock with great regularity, attaining to a height of from 3½ to 4½ feet, and crowned with pure yellow flowers 4 inches in diameter in August, September, and the early part of October. The plant is a good grower, free flowering, and it is not particular as regards soil and climate. It is not only a very showy border plant, but also a very serviceable one for providing cut flowers.—H. W.

— APRICOTS AT MAIDSTONE.—Apricots are excellently grown in the nurseries of Messrs. G. Bunyard & Co. at Maidstone, where a house has been erected specially for them. The sides, as well as the roof, are of glass, resting on three courses of bricks, and the central squares are removeable, so that abundant supplies of air, which are as necessary to Apricots as to Chrysanthemums, can be admitted. Copious supplies of water are given in summer, a little only in autumn, and none in winter. Mr. Bunyard attributes his success largely to the ventilation and watering. He also considers it best to plant out maidens, and not older trees.—W. P. W.

— LAO TEA.—The "Kew Bulletin" gives some interesting information as to Lao tea. Some time ago a singular method of using the leaves of what has since been proved to be the Assam Tea plant of commerce (*Camellia theifera*) was brought before the Society of Arts by Mr. Ernest Mason Satow. Amongst the Laos, a people inhabiting the district of Siam, in the neighbourhood of Chiengimai, the Tea leaves are not used for making an infusion, as in other countries, but are prepared wholly for the purpose of chewing. The leaves are first steamed and then tied up in bundles and buried in the ground, for a period of about fifteen days. Leaves thus prepared, called locally "mieng," are said to keep for two years or more. The habit of chewing "mieng" is almost universal among the Laos, and to men engaged in hard work, such as poling or rowing, it is said to be almost indispensable.

— GARDENING APPOINTMENT.—We understand that Mr. S. J. Brown has been appointed head gardener to Lady Cust, Leasowe Castle, Birkenhead, Cheshire.

— PRIMULA JAPONICA.—This plant seems quite at home here, growing in the grass by the side of shaded walks. Perhaps other readers have not grown it thus.—S. SCOTT, *Buckingham, Co. Roscommon*.

— CALIFORNIAN PEACHES.—A large number of Californian Peaches have been on sale in the metropolitan markets during the past week, but they do not maintain the reputation acquired at the commencement of the season.

— NATIONAL AURICULA AND CARNATION AND PICOTEE SOCIETIES.—The annual general meeting of the Southern Section of these Societies is announced to be held to-night (Thursday), Oct. 27th, at the Hotel Windsor, Victoria Street, S.W.

— BOUGAINVILLEA GLABRA.—As stated on page 339, this plant is quite safe in a temperature of 45° and much lower. I have known a large specimen stand a few degrees of frost several times during the winter without doing any injury, having flowered freely the following summer.—S. SCOTT.

— THE CARNATION AND PICOTEE UNION.—Mr. George Chaundy writes under date October 18th, 1892: "Mr. Dodwell is very seriously indisposed, and his physician, Dr. Rivers Wilson, insists upon his complete repose. The forbearance of correspondents whose letters may not have instant response is respectfully entreated." All the friends of the veteran will be pleased to hear of his speedy recovery.

— WEATHER AT LIVERPOOL.—On Sunday, Monday, and Tuesday evenings in last week we experienced rather severe frosts, the record being 6°, 9°, and 4°. Since then the weather has been of a most unsatisfactory nature, rain in torrents and severe hailstorms being very prevalent. It is a gloomy outlook for the farmers, and bad enough for those contemplating a large amount of planting.—R. P. R.

— NEW POTATO, BRINKWORTH'S HEAVY WEIGHT.—This fine Potato will, I think, be much grown in the future when its good qualities become well known. It is an enormous cropper, and is also of splendid quality when cooked. The tubers turn out like balls of flour, and so far as appearance and flavour go will, I think, suit everybody if we except those few individuals who prefer waxy to floury Potatoes. The tubers are large, handsome, and pebble-shaped, and should prove valuable for exhibition purposes. One slight drawback to this variety is that it makes a large amount of top growth; this may, however, be obviated to a great extent on some soils and during more sunny seasons.—H. DUNKIN.

— TWO PRETTY NEW FERNS.—The new Ferns I am about to notice are quite distinct, and are two of the finest introductions of late years. The "True Maidenhair," *Adiantum capillus-Veneris*, is one of the hardiest of Ferns, but add to this what I may term a miniature *A. farleyense*, then you have the true character of *Adiantum capillus-Veneris imbricatum*, the latest acquisition of the Chester firm of Dicksons. It is likely to prove itself a splendid Fern for decoration. *A. farleyense* in this respect is too tender, it quickly feeling the wear and tear of such work, but the Fern under notice worthily fills this void. The other, *Pteris Victoriae*, is not any the less remarkable, its slender, erect and narrow fronds being of a pleasing green margined with white, and will prove itself to be an elegant plant for table decoration. I am growing it in an intermediate temperature, but upon further acquaintance it will no doubt conform to cooler treatment.—A. Y.

— MARECHAL NIEL ROSE IN POTS.—I saw recently in one of the houses at Longford Castle gardens a quantity of very fine rods of Maréchal Niel Rose, which Mr. Ward had obtained by striking cuttings in warmth in February, and growing them on in pots. When I saw them they were some 15 to 20 feet in length, good hard wood tied up to the back of a house to mature. Such plants as these, literally like pot Vines, but longer, will next spring carry a grand lot of blooms, and then when the bloom is over can be cut hard back, induced to start afresh from the base of the stems, and then shifted into pots a size larger, will again carry grand growths for the following season. Myriads of pot plants of Maréchal Niel have been spoiled for good by the growers neglecting to cut them hard back as soon as the bloom is over. Then they have found only bare stems and a few thin pipey shoots to follow. As to the course adopted with such success by Mr. Ward it is only to say that he follows it up annually, and thus always has a fine lot of plants in pots to flower.—A. D.

— A CORRECTION.—In the list of certificates and awards given by the Royal Horticultural Society it was inadvertently printed in our last issue, "Mr. Seward, gardener to J. Shrimpton, Esq.," whereas it should have been Mr. Shrimpton, gardener to W. Seward, Esq.

— CROTON AUCUBAS.—This is the term that has been applied to the hybrid Aucubas of which Mr. George Paul is getting together a collection at Cheshunt, and it is a very appropriate one, for there are many Croton-like variations in the beautifully marked leaves. Some are blotched, others spotted, and still others striped with broad flakes. They will add much effectiveness to these useful plants.

— FRUIT GROWING IN IRELAND.—Mr. John Howard Parnell, who has taken possession of Avondale House, County Wicklow, has begun to experiment with some new industries in Ireland. He will embark in fruit growing, and it is said has already erected machinery for producing what is known as "wood-wool," a substance used for many purposes, amongst them the stuffing of mattresses and packing of fruit.

— THE INFLUENCE OF ELECTRIC LIGHT ON VEGETATION.—The researches of M. Bonnier on the growth of plants and trees under the influence of the electric light have led him to conclude that the electric light is decidedly less effective in promoting vegetation than solar light; but as he does not state the intensity of his artificial light as compared with that of solar light his conclusion is open to dispute.

— FRUIT CULTURE IN CORNWALL.—It is stated in reference to the fruit-growing industry in Cornwall that, "the latest idea is to start model fruit farms in various parts, and by the aid of the landowners to plant trees of all kinds and to utilise the best known skill for bringing on early fruit. It is calculated that in about two years and a half these farms will be not only self-paying, but will yield a good profit for the original outlay."

— CYPRIPEDIUM INSIGNE CHANTINI.—The pick of a choice collection of Cypripedium insigne varieties in the Old Nurseries, Cheshunt, is Chantini, a most beautiful Orchid, differing widely from the type in its markings. The broad margin of white to the dorsal sepal lends a charm and delicacy to the flower that cannot fail to please. C. i. alba marginata is also delightful. A collection of insigne is full of interest to Orchid lovers.

— TREES IN PARIS.—According to the *Revue de l'Horticulture Belge*, Paris contains the greater number of trees than any other city in the world. In the parks and Parisian gardens no less than 299,294 shrubs and 22,038 trees may be counted. The number of trees planted out in lines is about 100,000. Of all the quarters of Paris the best division is Passy. Then come the Champs-Élysées, Grenelle, Montparnasse, the Ternes, and Maison-Blanche. It is in the second district that the fewest trees are found.

— THE WEATHER IN THE NORTH.—The past week has been throughout cold, but the days generally clear and bright. Frosts of from 2° to 8° have occurred nightly, and this morning 15° are registered, with hoar frost as white as snow. For some days the surrounding hills have been coated for a considerable way down, and heavier falls of snow are reported from both north and south. Saturday last was piercingly cold. There is no appearance whatever of a change.—B. D., *S. Perthshire*. From Dumfries Mr. Arnott writes:—"Weather very cold. Snow on the hills this morning (Oct. 24th), but in sheltered situations in my gardens Dahlias and Tropæolums are still untouched by frost."

— TOMATOES: YELLOW v. RED.—"D.," on page 308, says: "The theory that yellow Tomatoes invariably have a higher flavour than red ones will not bear examination." Permit me to say that my crop of Tomatoes for the past year exceeds 2000 lbs., and that I am weak enough to grow a great number of sorts, simply to test their cropping and other qualities. I also consider I have consumed enough Tomatoes to be a judge of flavour. No variety I have yet grown is equal to Sunrise, an American introduction, but I find it has already been renamed by many seedsmen. Not alone is it superior in flavour, but the flesh is more solid than any red I know. There is certainly a prejudice against yellow Tomatoes, and they are not anything like the croppers that red ones are. I consider Tomatoes vary as much in quality as Plums, Peaches, and other fruits. Some of the sorts are little better than a mass of seeds and water. None of the oblong or Plum-shaped varieties are worth growing for flavour; even the Old Red and most of the corrugated fruits are only second rate compared with such varieties as Perfection with its many synonyms, Lorillard, and Red King.—W. J. C.

— A WIRE-BOUND APPLE TREE.—In a garden at Mayfields, Farnham, a Blenheim Orange Apple tree, says a contemporary, has a wire fence attached to a limb, the wire having been completely embedded in the bark, in tire-fashion. This year the particular branch is loaded with fruit, while other parts of the tree are nearly barren.

— A HEAVY RAINFALL.—It was stated recently by a correspondent that the fall of rain (2.65 inches), on the 4th inst., at Cross-in-Hand, Sussex, was such that "the oldest inhabitants of this district cannot remember anything like this rainfall." We ("Meteorological Magazine") think that the memory of these good persons must be failing rapidly, for as recently as July 31st, 1888, over an area of quite 100 square miles, and within about ten miles of Cross-in-Hand, if indeed it did not reach there, the fall was between 3 and 3½ inches.

— FROST IN THE ISLE OF WIGHT.—This morning (24th inst.) all our tender plants, such as Tropæolums, Dahlias, &c., were cut down by frost. We have had 5° with rather a keen north-easterly wind. The frost about a fortnight ago was very partial. At Newport, in the centre of the island, the Dahlias were killed to the ground, being a great loss to the several florists, as cut flowers were in great demand. It is the earliest frost that has been known here for a generation. In the valley, on the reclaimed land, the plants were only partly touched. Dahlias, Beans, and Vegetable Marrows having the top foliage killed; but in the villages here all the summer occupants have been gay until this morning.—C. ORCHARD, *Bembridge*.

— RUDBECKIA LACINIATA.—This is a fine late-flowering hardy perennial plant, producing its large handsome golden flowers borne on branching stems 5 feet high in August, September, and October. The individual flowers measure about 5 inches in diameter, the embossed chocolate coloured discs contrasting effectively with the beautifully golden florets. The Rudbeckia will flourish in any light well drained soil of average fertility, and preferably warm situation. R. maxima is a large form of the above, attaining to a height of 6 feet. R. Newmanni (syn. speciosa), and growing from 1½ to 2½ feet, according as the soil is poor or rich, is one of our best hardy plants in cultivation; yet we do not very often meet with it in gardens. All the Rudbeckias are very suitable for cutting from for garnishing large vases intermixed with Michaelmas Daisies.—H.

— BOUVARDIAS.—During the months of September and October there are few plants which tend to brighten the greenhouse more than Bouvardias. The treatment I give these free-flowering plants is to make a slight hotbed with leaves and stable manure about 1 foot high, and on this place 9 inches of loam and leaf soil in equal proportions. The plants are put out about the first week in June, and require but little attention except watering. They are kept well pinched back so as to form good bushy plants by the first week in September. At that period they are lifted and potted, the balls of the plants being reduced, so as to get them into pots or pans, which I find to answer much the best. After potting the plants are put into a warm house, and being kept close and shaded for a few days they are soon ready for the show house without losing any of the blooms.—A GARDENER.

— FUNGI DISEASES ON FRUIT TREES.—An excellent paper on fungous diseases and their remedies was read lately by Prof. J. E. Humphrey before the Massachusetts Horticultural Society, and has now been printed. One of the principles on which he insists is that the treatment of these diseases, to be efficient, must be preventive rather than remedial. He points out that it is not enough to take care that plants shall have abundant nourishment. No practice, he says, is more common among American fruit growers than to leave in the vinery and the orchard, lying on the ground or hanging from the branches, the dead fruits of the season, which have been rendered worthless by fungi. Nothing could produce more unhealthful conditions, for these dead fruits commonly furnish to the fungi which attack them precisely the most favourable soil for further and complete development. In the next spring the air is full of the spores of these fungi, which find lodgment on the new leaves and fruits of the very plants on which they grew last year; and so the story goes, year after year. "In a word," says Prof. Humphrey, "keep your orchards and gardens and greenhouses clean. Allow no rubbish to be about on which fungi can breed. Remove and destroy all diseased fruits or plants as scrupulously as you preserve saleable ones, and you will have more saleable ones to preserve. It is surprising how far generous culture and clean culture will go toward preventing fungous disease, without special treatment."—(Nature.)

— BOURNEMOUTH AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.—"The Composition, Uses, and Abuses of Farmyard Manure" was the title of an excellent paper read by Mr. A. Skinner, gardener, Highcliffe Castle, Christchurch, at the meeting of the above Society on Wednesday, October 19th. An interesting discussion followed, and Mr. Skinner was accorded a hearty vote of thanks. Mr. J. J. Swaffield, nurseryman, occupied the chair.

— PRESENTATION TO MR. A. MCLEOD.—On Tuesday, October 18th, the friends of Mr. Angus McLeod presented him with an address, accompanied with a purse of sovereigns, on his departure from Kells. Mr. McLeod was manager of Headfort Gardens for over six years, during which time the great interest he took in the promotion of Irish horticulture, together with his genial manners, won him many friends. His name figured as a prizetaker at most of the Dublin and at many local shows. Mr. McLeod is at present disengaged, and is succeeded by Mr. Hownslow, Lord Headfort's gardener at Virginia, who now manages both establishments.

— PLANTS AND FLOWERS BY PARCEL POST.—The regulations concerning the sending of plants and flowers, &c., by parcel post now indicate that tin boxes should always be used for Damsons, Bullaces, and Blackberries. Chrysanthemums should invariably be enclosed in a box or basket, as by this means all risk of damage is prevented. Shrubs and dwarf trees should have the roots encased in bass matting, and the branches and twigs tied together with bass or string. Dwarf standard Rose trees should have bands of hay or of bass matting wound round their entire length so as to prevent all risk of injury to the young shoots. Wooden boxes should be used for flowers and soft or tender plants. The address label attached to such parcels should bear the words "by parcel post," "fruit," "plant," &c., as the case may be, or "perishable," and every effort will be made by the authorities to deal with parcels so marked as speedily and carefully as possible.

— AILSA CRAIG ONION.—Replying to "R. M." in the *Journal of Horticulture*, page 329, I think I may safely assert that what Mr. Deverill is trying to obtain is an Ailsa Craig of a handsome globe-shaped form. What labour this means only practical onionists (who, like myself, have spent years of patient experiments) can comprehend; but as "R. M." truly observes, whether as a "globe" or "flat," Ailsa Craig is undoubtedly a magnificent exhibition Onion. What "R. M." and others will have to watch is that he obtains the finest strains only from selected bulbs, otherwise, as in the case of the cheap stocks of Rousham Park Hero (raised by myself), he will find that in years to come the Ailsa Craig will be without any character whatever. Perhaps nothing deteriorates so quickly as an Onion, and the care required to keep a variety up to exhibition excellence was amply illustrated at Deverill's last Onion Show by comparing the Rousham Park Hero Onions there exhibited with the low-priced stocks now so prevalent. I mention this as a comparison, and to show what we may expect Ailsa Craig to ultimately become in the absence of the closest care in selection.—H. WINGROVE, *Rousham Park Gardens*.

— TECHNICAL INSTITUTE, DUNDEE.—The Dundee Horticultural Association, having for its aims the advancement of the science and practice of horticulture, made application in the autumn of last year to participate in any sum set aside from "Residue Grant" by the Town Council for the purposes of technical education. This application was favourably received, and one of the conditions attached to the grant given to the Technical Institute by the Council was the institution of a class in the principles and practice of horticulture for gardeners. A course of about twenty lessons and demonstrations has been arranged. The class will be conducted by Mr. D. Storrie, who has been strongly recommended to the Committee as a skilful and enthusiastic botanist and horticulturist. The following subjects will be treated:—Introduction.—The three pathways of knowledge and the three kingdoms of Nature—the mineral, vegetable, and animal kingdoms; their relations and main divisions, with special reference to plants. The Mineral Kingdom, briefly considered in relation to horticulture.—Rocks and their reduction to soils; mechanical and chemical properties of soils; rough methods of soil analysis; improvement of barren and poor soils. The Vegetable Kingdom.—The higher and lower forms of vegetation; the fundamental structure of plants; different plant members (roots, leaves, &c.) and their functions. Plant Growth.—Absorption of food materials; respiration and transpiration; assimilation and increase of size and weight. Plant Reproduction.—Pollination; fertilisation and growth of the embryo; seed—their character and germination; practical management of seeds; propagation and practical management of bulbs,

corms, tubers, and root crowns; spores and viviparous buds. Ferns.—Their reproduction and life history; essential conditions for raising Ferns from spores. Plant Propagation.—Cuttings and layers; budding and grafting. Plant Cultivation.—Essential conditions of temperature and humidity; the effects of light, heat, and cold on plants; the principles of heating by hot water. The practice and principles of pruning. Planting and Transplanting.—Seasons and conditions of the soil; meteorological conditions determining success or failure; care and management of roots. Pot Plants and their Management.—Potting and composts; watering; capillarity and evaporation; airing, shading, and syringing. The Chemistry of the Soil.—Plant foods and plant constituents; manures, their management and applications; theory of rotation of cropping. Garden Pests.—Fungoid and other vegetable pests; insect pests. Botany.—A course of one lecture weekly during the summer term will be given by Professor Geddes. In 1893 the course will deal with "Systematic and Economic Botany and the Geography of Plants." No previous knowledge is required; but the course will cover natural orders of plants not undertaken last year. The class will meet on Tuesdays at eight, beginning Tuesday, 3rd May. Students may attend the botanical excursions. As far as possible, assistance in pursuing botanical studies during the vacation will again be given. Fee, 5s.

— GARDENERS' ASSOCIATION LECTURES.—The remarkable case of plagiarism which Mr. Barron has brought to light in respect of a lecture delivered to a gardeners' association very naturally leads further to the query, How many such cases are in the habit of occurring under the same conditions, in which information taken from books is palmed off as practical knowledge? But I would ask of gardeners' associations whether in obtaining lectures or papers of the description referred to in a fragmentary way they are really performing for their members very much of useful service. A winter course of lectures should, so far as possible, be made exhaustive of some section of horticulture. There should be connection and continuity in what is undertaken, so that at the conclusion of a session it might be said that real educational work has been performed. If the proposed scheme relating to horticultural examinations, now under the consideration of the Council of the Royal Horticultural Society, be finally formulated, and gardeners' associations invited to send members for examination, they will find the greater need for courses of lectures that have definite relation to the subjects found in the examination syllabus.—A. D.

— MONTBRETIA CROCOSMÆFLORA.—In reference to the Rev. C. Wolley Dod's remarks (page 58), as to the hardiness of Montbretias, I may state that with Chancellor Swayne, The Close, Salisbury, the Montbretias are quite hardy. I had my Montbretias from that noted cultivator of hardy perennial and alpine plants last spring, and I believe that these beautiful and highly useful plants will prove hardy in most gardens in this country if they are planted deep enough in light well-drained soil in a dry warm situation, to be out of the reach of frost. In our case the herbaceous borders are raised above the soil surrounding them and slope to the walk, which runs nearly north and south. The soil is a light loam, enriched with leaf soil, short manure, and wood ashes, and from 2 to 3 feet in depth, resting on a gravelly sub-stratum. Still, where there is doubt about the hardiness of this plant in soils and situations less favourable to its perfect safety than those indicated, a few inches thick of sifted coal ashes or leaf mould placed over the roots on the approach of winter would render them quite secure from frost.—H. W. W.

— WOOLTON GARDENERS' MUTUAL IMPROVEMENT SOCIETY.—On Thursday evening the second meeting of this useful Society was held in the Mechanics' Institute. Mr. D. H. Johns occupied the chair, and the following short papers were read—viz., "Helianthus," by Mr. R. Todd, gardener to Holbrook Gaskell, Esq., Woolton Wood; "Violets," by Mr. J. Stoney, gardener to Sir Thos. Earle, Bart., Allerton Tower; "Chrysanthemums," by Mr. T. Carling, gardener to Mrs. Cope, Dove Park, Woolton; "Pyrethrums and Anemones," by Mr. R. G. Waterman; and "Potatoes," by Mr. T. Leadbetter. The papers proved most interesting, as was also the excellent display of flowers and vegetables. Mr. W. Piercy, Forest Hill, London, sent a box of early-flowering Chrysanthemums, for which he received the Society's special thanks, together with a certificate of merit. Certificates were also granted to A. S. Lowndes, Esq. (gardener, Mr. W. Harrison), for Dahlias; to Mr. J. J. Craven, gardener to G. Grant Morris, Esq., Allerton Priory, for hardy flowers; to Mr. J. Stoney for Vegetables; and to Mr. T. Leadbetter for Potatoes, showing good examples of a new Potato named Magpie, also Maincrop, Early Regent, and others. The statement of accounts of the recent

concert given by the Society in aid of the Gardeners' Royal Benevolent and the Gardeners' Orphan Fund showed a balance of £10 8s. 6d., which will be divided between the above charities. A vote of thanks to the Chairman concluded the meeting. The following meetings are to be held during the first half of the session:—November 3rd, "Vegetarianism," by Mr. E. Baillie, Chester; November 17th, "Bouvardias," by Mr. G. Glover, gardener to Sir Andrew B. Walker, Bart., Gateacre Grange; December 1st, "Culture of Stove Flowering Plants," by Mr. B. Cromwell, gardener to T. Sutton Timmis, Cleveley, Allerton. Lectures have also been arranged on "Agricultural Chemistry" by T. Lewis Bailey, Esq., Ph.D.—R. P. R.

A FERTILE BOUGH.

ABOUT ten years ago in an idle moment I inserted on the lowest growth of a *Beurré d'Amanlis* Pear a bud of *Passe Colmar*. It grew freely and soon came into bearing, and has since fruited every year with

owe their sporting nature to a change of soil or situation; but this is not always the case, as I have known a variety to sport in different localities in the same season, and the sports to be identical. Take, for instance, the variety called *Sunrise*, raised five years ago by Mr. J. Baxter of Daldowie, a dark rose coloured self *Viola*. This has to my personal knowledge sported this year in at least three different localities—namely, at *Rothesay*, *Chiswick*, and in my own garden at *Chingford*. In each case the entire plant has sported; the sport is a dark striped flower of great size and substance, but with the defect of *Sunrise*—short footstalks to the blooms. I have called it "*Radiator*," thinking this a suitable name; it is the finest striped *Viola* I have yet seen.

The *Viola* called *Delicata*, a lilac coloured self flower, has also sported at *Chiswick* Gardens into a light striped variety; it sported entirely in every plant. From *Columbine* we have various sports, the best known of which are *York* and *Lancaster* and *Lucy Ashton*. *Ardwell Gem* has perhaps given us the two most popular *Violas* of to-day—namely, *Goldfinch* and the sport from *Goldfinch*, the

FIG. 51.—A GRAFTED PEAR, PASSE COLMAR.

increasing crops. Last year it set its fruit so abundantly that I was obliged to cut off two out of every three Pears. The crop which ripened was prodigious, and the bough required many supports. Two hundred and forty-two Pears were actually gathered after about thirty had fallen off. The fruit ripened perfectly but was small. Unfortunately I did not have it photographed as a curiosity, for such a crop had never been seen by me or my friends before. I anticipated that this excessive fertility would have exhausted the bough, but the result has proved otherwise, for although the crop this year is considerably reduced in number the fruit is much finer. Eighty-six of the *Passe Colmar* Pears were gathered a few days ago, weighing 15 lbs., while the stock tree *Beurré d'Amanlis* has not produced more than half a dozen fruit, it having failed for the first time this year in common with most of my Pear trees to yield a crop. I send you a photograph of the bough. Fig. 51 represents it.—EDMUND TONKS, *Packwood*, October 19, 1892.

VIOLA SPORTS.

FEW growers recognise the fact that many of our finest *Violas* are the result of sports from other varieties, and perhaps a little information on the subject may be interesting. *Violas* sometimes

charming *Duchess of Fife*. The last-named variety is also sporting; I have this season seen two sports from it, almost pure white flowers, one with the markings of *Duchess of Fife*, the other having a dark purple edging, and I think a slight improvement on last-named variety. Once a sport is secured it very rarely reverts to the original variety from which it sported. I have, however, seen in two instances *Goldfinch* sport back to *Ardwell Gem*. When a *Viola* sports in the entire plant there is no difficulty in securing it, but the sport very often shows itself in the blooms on a single stem of a plant, all the remainder of the plant retaining its originality. The various ways of securing a sport are as follows:—Take the stem showing the sportive bloom up with as much root as it has attached to it, and carefully replant it; or cut the stem through, about 2 inches lower than the joint from where the flower stem is, and plant as a cutting. I have secured sports by both methods, but I have occasionally failed.

Young growers like myself have much to learn; but I am very grateful to my old friend Mr. William Dean for information on the securing of sports. In conversation with him lately he quite agreed that there was an uncertainty, although slight, in the securing of sports, and gave me another method by which the sport might be secured—namely, by allowing the sportive bloom to seed and raising seedlings from it. I have not had an opportunity

of testing this method. Violas are more sportive late in the autumn than at any other season of the year.—GEO. MCLEOD, F.R.H.S., *Chingford*.

CHRYSANTHEMUM SHOWS.

WE publish a list of Chrysanthemum Shows to be held during the next few weeks, and shall be glad to receive from readers the notification of any exhibitions that are omitted from the following :—

- Oct. 27th.—Gosport.
- " 28th.—Havant (two days).
- Nov. 1st.—Kent County (Blackheath, two days).
- " " Brixton (two days).
- " " Barnstaple (two days).
- " " Watford (two days).
- " " Ipswich (two days).
- " " Brighton and Hove (two days).
- " 2nd.—Croydon (two days).
- " " Portsmouth (three days).
- " " Ealing (two days).
- " " Evesham.
- " " Ascot (two days).
- " " Isle of Thanet (two days).
- " " Guildford (two days).
- " 3rd.—Wells (Somerset, two days).
- " " Highgate.
- " " Hertford (two days).
- " " Steyning.
- " " Pembroke.
- " " Stroud.
- " " Grimsby (two days).
- " 4th.—Crystal Palace (two days).
- " " Bolton (two days).
- " " Tooting.
- " 5th.—Crewe.
- " 7th.—St. Neots.
- " 8th.—National (Aquarium, three days).
- " " Kingston (two days).
- " " Sevenoaks (two days).
- " " Leeds (two days).
- " " Batley (two days).
- " " South London (Camberwell, two days).
- " " Waterlow (Liverpool, two days).
- " " Truro (two days).
- " " Enfield (two days).
- " " Eastbourne (two days).
- " 9th.—Hornsey (two days).
- " " Birmingham (two days).
- " " South Shields (two days).
- " " Cardiff (two days).
- " " Cirencester (two days).
- " " Bournemouth (two days).
- " " Battersea (two days).
- " " Chelmsford (two days).
- " " Market Harborough (two days).
- " " Bath (two days).
- " " Barnsley (two days).
- " 10th.—Finchley (two days).
- " " Birkenhead and Wirral (two days).
- " " Stirling (two days).
- " " Spalding (two days).
- " " Tiverton (two days).
- " " Winchester (two days).
- " " Westerham.
- " " Chelmsford.
- " " Dawlish.
- " 11th.—Leicester (two days).
- " " Eccles and Patricroft (two days).
- " " Wellingborough (two days).
- " " Dundee.
- " " Sheffield (two days).
- " " Hitchen.
- " " Bradford (two days).
- " " Devon and Exeter.
- " " Derby (two days).
- " 15th.—Plymouth (two days).
- " " Liverpool (two days).
- " " Twickenham (two days).
- " " Hartlepool (two days).
- " " Reading (two days).
- " " Wimbledon (two days).
- " 16th.—Hull (two days).
- " " Bristol (two days).

- Nov. 16th.—Hanley (two days).
- " " Rugby (two days).
- " " Lewes (two days).
- " " Hinckley (two days).
- " " York (two days).
- " 17th.—Edinburgh (three days).
- " " Neath (two days).
- " " Wantage (two days).
- " " Norfolk and Norwich (two days).
- " " Rotherham.
- " 18th.—Stockport (two days).
- " " Chorley (two days).
- " 22nd.—Dalkley.

NATIONAL CHRYSANTHEMUM SOCIETY AND ITS CERTIFICATES.

A CASE has been brought to our notice that astonished us, and we feel bound, both in the best interests of the N.C.S. as well as of exhibitors of new varieties, to place it before the public. This excellent Society has done yeoman's work for the Chrysanthemum, its growers, and exhibitors, and its certificates, which are justly valued by their possessors, also carry the weight to which they are entitled with the public. Varieties that are honoured are much sought for, while those which fail to win the hall-mark of excellence are correspondingly disregarded. It is imperative, therefore, that every member of the Floral Committee of the N.C.S. be not only fully competent as a judge of Chrysanthemums, but he must also be absolutely free from even a suspicion of prejudice. That the members of the Committee as a body are competent no one can doubt, and as a body also they are men of the highest probity; but if there is even one among them who can permit himself to act equivocally the fair fame of the Society is bound to be jeopardised.

A few weeks ago our advice was requested on bringing a new Chrysanthemum before the public, though we are informed it had been previously exhibited. We suggested to the raiser that he should have blooms placed before the Floral Committees of the N.C.S. and R.H.S. for certificates. Several (Beauty of Exmouth and Duchess of Devonshire) were brought to the last Aquarium Show. Mr. Godfrey states that on his boxes being opened one of the members of the Floral Committee of the N.C.S. and an exhibitor of varieties for certificates advised him to put the Duchess under the table, and not to place blooms before the Committee; another member and introducer of new varieties spoke disparagingly of the Beauty of Exmouth, first as being identical with another variety, but "only half the size," then subsequently complaining that "there was too much stuff in it." Mr. Godfrey, however, placed his blooms before the Committee, at which twelve or fourteen members were present, including the two exhibitors referred to. On the motion being put to the meeting that a certificate be granted to the Beauty of Exmouth, one of these exhibitors immediately opposed it as not being distinct, and in consequence only four hands were held up in its favour. Mr. Godfrey on being appealed to defended its distinctness, and a bloom of the variety alleged to be similar was, on the proposition of Mr. Cannell, obtained from the show, and found to be dissimilar and inferior, and Beauty of Exmouth was honoured by eleven votes against two.

Mr. Godfrey next distinctly states, and is prepared to stand by his statement, that after the meeting was over the chief opponent of his blooms said he only acted as he had done because "he had a white of his own that he was very fond of and wished to run," and the Exmouth variety would "cut it out;" then, as Beauty of Exmouth secured the honour, this member of Committee asked Mr. Godfrey "if he would take a good figure for the stock," and on receiving a negative reply, wished to know the "price per hundred" with a view to purchasing plants, on the ground that "such a variety would be sure to sell"—the variety which he had strenuously opposed and nearly succeeded in preventing its obtaining the honour—it clearly deserved and won on its merits.

If the above is a substantially correct statement of the case—and we know that Mr. Godfrey's narrative of what transpired in committee is accurate—a full investigation appears to be called for by the National Chrysanthemum Society if it is to maintain its status as the chief Chrysanthemum authority in this country.

Mr. Godfrey sent his letter for publication, and was particular in requesting that his name should appear with it. We do not publish the letter at present, and make no charges, but state the case fairly and moderately as requiring investigation. With that object, and with the full and frank permission of Mr. Godfrey, we placed a copy of his letter in the hands of the officials of the Society last Monday; and a strong sub-Committee has been appointed, consisting of Messrs. R. Ballantine, Chairman; E. C. Jukes, Vice-Chairman; J. Starling, Treasurer; Harman Payne, Foreign Secretary; and R. Dean, Secretary of the N.C.S., to consider the whole subject. The result of the investigation will, as we earnestly hope, allay prevailing disquietude, and thus increase the influence and prosperity of a Society which has attained a high position in the horticultural world.

THE NATIONAL CHRYSANTHEMUM SOCIETY'S CATALOGUE.

NOW that the Chrysanthemum season has commenced, the above useful publication should be in the hands of all growers. It contains complete lists of the various sections, corrected and brought up to date, as well as an alphabetical list of varieties in cultivation, to which reference can be readily made. For the modest sum of 1s. that and the schedule of prizes, which contains some valuable papers read at

conferences, can be obtained from the Secretary, Mr. R. Dean, Ranelagh Road, Ealing.

THE GREAT FLOWER-STAND CONTROVERSY.

I CALLED upon Mr. George Woodgate, the estimable Secretary to the Kingston Chrysanthemum Society, the other day, to learn his views on the subject now exciting the attention of Chrysanthemum growers so largely, that is, the proposed increase in the size of the show stands for Japanese flowers. The Kingston Society is one of not the least important around London, and the views of its chief executive officer, who is also a grower and an exhibitor, merit attention. Mr. Woodgate was present at the meeting reported in your columns last week, but could not remain to learn the final decision. He generally agreed with the purport of Mr. Shea's paper, thought it presented an admirable summary of what was to be said in favour of the change, and also thought that a change being determined upon it would be folly to have other than one of a complete and satisfactory kind. All the same Mr. Woodgate is no special admirer of big blooms, and rather fears that the concession now proposed to be made to big flowers by so materially enlarging the show boards will rather tend to the wider culture of big, and as a rule, coarse bloom varieties rather than those refined and beautiful varieties which, if wanting size, yet have elements of quality which it should be the desire of all to retain. If, said Mr. Woodgate, judges would lay more stress on depth or solidity in Japanese flowers and less on mere size, it would do much to check the present tendency towards favouring the large flowers. Then again, if the boxes are enlarged how will the front row blooms look at 7 inches apart unless they, too, are of the big section? Practically, the proposed enlargement will be putting a premium on size or breadth at the expense of depth, refinement, and beauty. Again, the incurved section we cannot enlarge if we would. There is little probability that of these we shall ever see finer flowers than the Queen and Empress types give now, and these will therefore look more dwarfed than ever when the Japanese boxes are 3 inches wider, and the blooms increase from 5 to 6 inches to 6 to 7 inches in diameter.

So far as Kingston is concerned, this year at least, there will be no change; indeed, the matter of alteration, whatsoever may be done in London, must be left to the exhibitor members of the Society to determine. Any unanimous alteration in the size of the boards so far as the Kingston Society is concerned can only be made by the members in general meeting, and when made they must be embodied in the schedule next year. With respect to the champion cup class, which has always attracted such good competition at Kingston, Mr. Woodgate thinks that it would not be a congruous one to have should it be determined to enlarge the Japanese boards. The class then with twenty-four incurved and twenty-four Japs as it is at present would wear such an irregular aspect that all its present charms would be destroyed. With respect to the taking out of the Jap section all such specially big forms as W. H. Lincoln, Stanstead White, Etoile de Lyon, and some others, and making a class for them, Mr. Woodgate sees no insuperable objection, so that for all ordinary blooms the old boards would still answer fully. He would like to see some check also put upon the methods of setting out the blooms by the aid of wires, as these tend to broaden the base of the blooms, to cure any artificial appearance of breadth, where if the lower petals were allowed to droop as they naturally do, greater depth would be reached and the beauty of the blooms much enhanced.

As to the encroachments made by the new boards on table space, Mr. Woodgate regards it in a more reflective aspect than some others have done. At Kingston they rarely, as it is, have one inch too much, and cannot spare room for more tabling; that is out of the question. It was said at the Aquarium meeting that the additional table room required with the enlarged boxes would not exceed 3 inches per yard, but that is below the mark. It would really be nearer to 5 inches, and on a table 20 yards long that would mean abstracting 100 inches, or nearly 3 yards, a matter of supreme importance. It would seem evident, therefore, to meet such a difficulty that some small classes would have to be cut out of the schedule that this ardent favour shown for big blooms might have full play. It was mentioned at the meeting referred to that in connection with the Rose, for instance—and the Dahlia might have been referred to also—uniformity of staging was invariably found. So also is uniformity in judging, yet here we have judges invited to depart from that unanimity found in judging the flowers named where quality and body have ever found the chief places in favour of size, specially in the Japanese Chrysanthemum. I suggested to Mr. Woodgate that he should get a board made of the new size, place some good blooms in it, and exhibit it at the ensuing Kingston Show. That he will probably do, and thus exhibitors and others will have a good object lesson before them. It would be well if that proposal were generally adopted at Chrysanthemum shows next month.—A. D.

PIERCY'S SEEDLING.

THIS is a most useful early variety, flowers of fair size, colour a good bronze, compact in growth, and very free, and having a good constitution it is certainly worth a place in gardens where early autumn flowers are required in quantity. We have now plenty of bushes of this kind 6 feet in circumference and one mass of flower, and have been for some weeks past, from cuttings inserted last autumn in a cold frame, planted out in early spring in various parts of the garden, stopped once or twice, and then allowed to grow at will. Thus their culture entails but little trouble, and this, added to the other good points of this variety, makes it a valuable acquisition. A great many of the early ones are not definite enough in colour, and this is the only one I could select

from about a dozen bought in some two years ago, that was of any particular merit. Others we grow are Madame Desgranges, G. Wermig, Précocité, and Canary, the last-named much like the preceding, but paler in colour, the blooms somewhat smaller but neater. These grow and flower so freely that one might almost say they are perpetual bloomers, and last a long time in perfection when cut that in places where a large demand exists these are some of the things to grow where you can "cut and come again." With this communication I send you a few sprays of the above.—J. J. C.

[The bunches sent show the floriferousness of Piercy's Seedling, and its bronzy gold colour renders it effective for garden and room decoration.]

CHRYSANTHEMUM MADAME LOUISE LEROY.

IN the hurry after novelties some of the older varieties are apt to be forgotten. The variety under notice cannot be termed old by any means, it being introduced four or five years since; but after the first flourish of trumpets it dropped into the background. I consider it one of the finest white Chrysanthemums in cultivation, either as a large flower or as a bush grown freely without disbudding. It is really a splendid flower, also a capital keeper, the pearly-white petals standing out, but not too formally, and being of this form it is proof against damp. I have flowers now fully developed in the conservatory, and expect them to last in good condition for quite three weeks. It kept good last year for almost a month. This season I have several plants, a group in the conservatory being very effective. The flowers commenced to unfold the last day of September, and now (October 21st) they are almost fully developed, and I expect them to last for another three weeks. What other variety is there so lasting?—A. YOUNG.

CHRYSANTHEMUMS IN NORFOLK.

UP to the present time I have had only one opportunity afforded me of inspecting a really first-class collection in this county, although there are numerous good cultivators in Norfolk. I do not, however, expect to find better flowers than those I saw on Thursday last at Sennowe Hall, the residence of B. Le Neve Foster, Esq. Mr. W. G. Gilbert, the gardener, is well known to Chrysanthemum men as a prominent and successful exhibitor, and judging by the present appearance of his plants and flowers he will be even still better known at the close of the present season's campaign. A large light airy Peach house is filled with splendid Japanese, and what strikes one most on entering is the uniform dwarf habit of the plants, coupled with stout stems and large robust foliage. The average height of the plants will, I believe, scarcely exceed 4 feet. Most of the best new varieties are represented. Especially good is W. Tricker, broad florets, deep flowers, highly finished. Gloire de Rocher is also grand on many plants, better than I have before seen it. The same may be said of Kioto, Louis Boehler, Pelican, Stanstead White, Vivian Morel, Avalanche, Eynsford White, and Etoile de Lyon, these opening splendid flowers.

I was not a little surprised to see that Mr. Wells, of Earlswood Nurseries, Redhill, is not the sole possessor of the white sport from Vivian Morel. Mr. Gilbert has a plant carrying two flowers, one of which is a large white bloom slightly tinged pink, but promising to be pure white when fully expanded; the other is of the normal type and colour. Thus the truth of the assertion that when a sport from a well-known variety is announced we expect to hear of its having appeared simultaneously in one or more other places is again about to be demonstrated. Mr. Gilbert's flower will, I believe, be seen at the Aquarium Show.

He has also two very fine seedling Japanese. One is a large deep creamy-white flower, having the build of Belle Paule, with, like it, long curly florets, falling downwards; the florets broad and stout, in every way a fine exhibition flower, is named Mrs. Le Neve Foster. The other is an incurved Jap., somewhat resembling Mons. Freeman in form; colour deep old gold, with a silvery turnover. Another house contains a batch of incurved varieties, not yet far advanced, but opening very fine buds. Mrs. Robinson King is in good condition, opening fine flowers.—W. K. WOODCOCK.

FINSBURY PARK.

FOR years past the Chrysanthemums at Finsbury Park have been so good that an excellent display is now annually looked for by those interested in the matter. This season is no exception to the rule. The plants possess a remarkably dwarf sturdy habit and dark green foliage, which, as everyone knows, are indications of good blooms. Owing to securing the buds early this season Mr. Melville, the Superintendent, assisted by his lieutenant, Mr. Batchelor, has managed to be the first in the field so far as the metropolitan parks are concerned. The plants are arranged in a large span-roofed house near the Manor House entrance to the Park, and have been on view since October 1st. Many of the early flowering varieties are past their best, but there are numerous Japanese sorts just now in the zenith of their beauty, whilst the incurves will be fully a week or ten days before the blooms are properly expanded.

About two dozen of the newer varieties are grown, but in order to ensure a good display many of the old standard sorts are given a prominent place, and we think wisely. Elaine has been exceedingly fine, though now past its best, there being many sturdy plants carrying splendid flowers. Avalanche, too, is superb, and the same may be said of Edwin Molyneux. The popular Mdle. Lacroix has contributed largely to the display, as likewise has the old Peter the Great, still one

of the best yellows in cultivation for decorative purposes. Edouard Audiguier is grand, the blooms being large, of good substance, and richly coloured. Etoile de Lyon attracts attention with its massive blooms, as also does Condor, the flowers of the latter being very fine.

Among other varieties Mons. R. Bahuant is excellent, the flowers showing great depth and width, as also are Vivian Morel, Amos Perry, Louis Boehmer, Mr. Charles E. Shea, and Bouquet de Dame.

As already mentioned, the majority of the incurved varieties were not open at the time of our visit, but were looking remarkably well. Lord Alcester had developed several excellent blooms, as also had the well known varieties Golden George Glenny and Prince of Wales.

CHRYSANTHEMUMS AT CASTLE HUNTLY.

The residence of Mrs. Armistead in Perthshire has for the past six years been celebrated for Chrysanthemums. Mr. Beisant, the gardener, is well known as an enthusiastic grower, and also an enterprising and successful competitor; and, judging from the appearance of his 500 plants which I had the pleasure of seeing the other day, we are likely to see and hear more of him this season than hitherto. The majority of his plants are of medium height, and carry three blooms each. The shoots are thoroughly ripened and very brown, with strong thick leathery leaves. The plants are arranged in light, airy, span-roofed houses, with most of the buds within a foot of the glass. The majority of the Japs were showing colour, and what grand buds! Mr. Beisant finds them a fortnight later this season, and is now assisting them with fire heat. Amongst new varieties, Edwin Beckett, Mrs. E. Beckett, and W. K. Woodcock were extra fine. The most promising Japs in the general collection were Florence Davies (grand), Vivian Morel, Louis Boehmer, Cesare Costa, Sunflower, W. W. Coles, Edwin Molyneux, Etoile de Lyon, and Stanstead White. Bouquet des Dames, W. H. Lincoln, and Madame Louise Leroy were fully developed and most magnificent blooms; the latter is a great favourite at Castle Huntly.—VISITOR.

CHRYSANTHEMUMS AROUND LIVERPOOL.

MR. CARLING of Dove Park, Woolton, has some very promising plants both in the older and newer varieties. All the types of the Queen and Princess family look capable of producing fine flowers. In the newer varieties one which stood out more prominently than the rest was Felix Cassagneau. Although a weak plant the flowers were very fine, reminding one of Criterion in shape, but with a colour many shades deeper. W. Tricker, Madame Mezard, Mr. and Mrs. Beckett, Beauty of Castle Hill, Beauty of Castlewood, W. K. Woodcock, Mrs. Libbie Allen, Lilian B. Bird, Florence Davis, A. H. Neve, May Tomlin, and Ami Hoste should all turn out well. A variety named Mohawk was conspicuous by its fine shapely buds and dwarf habit. Very good, too, were Sarah Owen, Madame J. Laing, Sunflower, Boule d'Or, and Val d'Andorre. About 100 seedlings in 6-inch pots are being tried. Several of these looked well as regards habit and buds.

HIGHFIELD, WOOLTON.

Mr. Haigh does not exhibit, but as he grows 600 plants of the most sterling varieties in excellent style he is deserving of a short note. The plants, which are well arranged in the large plant house and in the Peach houses, are remarkable for their dwarf habit and excellent foliage. The Queens and Princess family are well ripened, sturdy, and just right for producing clean and good shaped flowers. Felix Cassagneau was here very fine, as also were Bouquet de Dame, Gloire du Rocher, Vivian Morel, Lilian B. Bird, W. K. Woodcock, and Mr. and Mrs. Beckett; whilst Richard Parker (grafted) had shapely buds just showing colour. A feature which might oftener be imitated, and especially by those having a large amount of decorative work to do, was a stage filled with plants from 15 to 18 inches high in 6-inch pots, and carrying just one flower.

CAMP HILL, WOOLTON.

Perhaps on no former occasion has Mr. Jellicoe had such a promise of fine flowers as the present. That he will be hard to beat no one having seen the plants can for a moment doubt, and whoever does it will have a tedious task to perform. In all the 800 plants grown it would be difficult to find a poor one. True some are rather early, but there are plenty to fall back upon. The Queen family are superb, and so are Princess and its sports. Stanstead White, Florence Davis, Mrs. Falconer Jamson, Miss Anna Hartzhorn, and Puritan I singled out as deserving special mention by reason of their extra quality. Mr. J. Stanborough Dibber, Mdllc. Marie Hoste, Louis Boehmer, Sunflower, Volunteer, and M. R. Bahuant were grand. Madame Darrier (incurved) ought to prove good, as no doubt will H. Ballantine, one of the hairy types, Mr. Jellicoe had some beautiful blooms of Mrs. Alpheus Hardy.

ALLERTON HOUSE, ALLERTON.

Here Mr. George Eaton has 300 well grown plants. He is particularly strong in the Japanese, having Sunflower, Boule d'Or, Etoile de Lyon, Stanstead White, W. H. Lincoln, Florence Davis, Gloire du Rocher, Mdllc. Marie Hoste, W. W. Coles, Mr. and Mrs. Beckett, and Alberic Lunden all very fine in bud. The Princess type are all good; Queens rather late but promising. Robert Cannell and Mons. R. Bahuant very good. His reflexed varieties are all represented by sturdy plants.

HILLSIDE, ALLERTON.

Another exhibitor who came out with a fair share of success at Liverpool last year was Mr. Healey. He has been persevering, and this

year his plants are looking very well. Princess of Wales, Mrs. Heale, and Mrs. S. Coleman are the best of that section. The Queen types are good, and Mons. R. Bahuant is very fine. The best amongst the Japanese are Condor, Stanstead White, Criterion, Etoile de Lyon, W. W. Coles, Mdllc. Marie Hoste, Vivian Morel, and Florence Davis.

CROFTON, AIGBURTH.

There are 400 plants grown here, and Mr. Donald Forbes ought to feel proud of them. In the Japanese, Mrs. E. W. Clarke, Boule d'Or, W. W. Coles, Florence Davis, and Stanstead White are very promising, whilst Mdllc. Marie Hoste and Mr. Edwin Beckett are the best I have seen as yet. Nearly all the newer Japanese are being tried. The following were all showing remarkably well: G. C. Schwabe, F. W. Flight, Holborn Dragon, J. D. Salter, W. K. Woodcock, Coronet (excellent), W. Tricker, Gaetano Guelfi, a creamy white variety with spreading petals; Anatoli Cordonna, a large white variety with broad straight petals; a very large flower; Madeline Davis, a beautiful incurved Japanese; Comte de Laurane, a variety of a lovely pink shade; Mr. G. Herring and La Verseaux. The Queen family was fine, as were the Princess, the latter a little later. Rt. Cannell, Mrs. Robinson King, Miss Bella Wilson, Miss B. V. Robinson, Mons. R. Bahuant, all showing very good buds. Fred Hart, a new reflexed, was very fine.

LINGDALE LODGE, OXTON.

As a most successful exhibitor, Mr. George Burden needs very little introduction. This year the incurved are very promising, the following being especially fine: The Queen family, Princess of Wales and their sport Prince Alfred, Lord Wolseley, Jeanne d'Arc, John Salter, Princess Beatrice and its sport Jardin des Plantes, and Mr. Bunn. Of newer ones, Mons. R. Bahuant is very good, whilst Robert Cannell and Mrs. Clibran are looking well. In Japanese, Vivian Morel, Stanstead White and Surprise, W. H. Lincoln, Sunflower, Etoile de Lyon, Mrs. F. Jameson, Florence Davis, Edwin Molyneux, and Bouquet de Dame of the older ones, and Elliott F. Shepherd, Mr. and Mrs. Beckett, and W. K. Woodcock of the newer varieties, are the most promising.

MOSSLEY HOUSE, MOSSLEY HILL.

Judging from present appearances the splendid collection of 350 plants grown here by Mr. D. Heany must, as regards excellence of quality, run those of Mr. Jellicoe very closely. For the number it would be difficult to see them surpassed, and Mr. Heany is almost certain to be heard of in the course of the next few weeks. The Queen and Princess families are grand, and here I saw Richard Parker most promising. Mons. R. Bahuant was enormous on some early buds, but there are more in reserve in a later stage. John Salter, Ami Hoste, Mrs. Clibran, Robert Cannell, and Mrs. F. Mistrell and Camille Flamarion are certain to produce excellent blooms. In the older Japanese Stanstead White, Avalanche, Etoile de Lyon, Boule d'Or, W. W. Coles, E. Molyneux, Condor, Madame Laing, Sarah Owen, Mrs. Falconer Jameson, and Bouquet de Dame are all good. The newer ones very promising are Elliott F. Shepherd, Violet Rose, Vivian Morel, Lilian B. Bird, A. H. Neve, R. C. Kingston, F. Clinton, Felix Cassagneau, Gaetano Guelfi, W. H. Lincoln, W. Tricker, Mrs. Irving Clarke, Louis Boehmer, Mrs. A. Waterer, and Miss Anna Hartzhorn.

Damping has been very prevalent amongst the earlier blooms; this is being guarded against by placing tiffany, which covers the roofs of the houses. The plants throughout are all free from mildew, and look very well.—R. P. R.

VINES AND VINE CULTURE—AN APOLOGY.

WE have received the following communications, which are creditable to both parties. Mr. McCormick, we have reason to believe, is a competent grower of Grapes, and was not aware of the nature of his transgression. Had he acknowledged the source of the matter that he appropriated Mr. Barron would not have made the complaint, for which he had such abundant justification:—

TO MR. A. F. BARRON.—Dear Sir,—I regret very much that the essay referred to on page 349 of the *Journal of Horticulture* should have given offence to anyone. I assure you, however, that the portions you complain of as being bodily taken from your work describe what I have carried out in practice during the last ten years, and I used your work simply to enable me to bring it out in a more concise form than I might otherwise have done. During the last twenty years I have taken a keen interest in everything appertaining to the Vine, and after comparing notes taken during that time with your work, which I assure you I very much value, I found it impossible for me to get away from the plain facts there recorded. Had it occurred to me that I was committing an error I should certainly have consulted you before I submitted the essay either to the Society or any other place.—I, am, dear Sir, yours very truly, JAMES MCCORMICK.

I accept the foregoing apology from Mr. McCormick as suitable and satisfactory, and beg to express my sincere regret that it should have been necessary to draw attention to anything of the sort. I am gratified by the notice "Vines and Vine Culture" receives from the gardening community, whilst anxious to secure the full credit for my work, which is my chief reward.—A. F. BARRON.

HARDY FLOWER NOTES.

EVEN now the darkness of the night swiftly enroaches upon the brightness of the day the garden withholds not its reward from the wooer of its favours—from him who, through sunshine and storm, cherishes his flowers, courting their favour by all the little arts his knowledge of which has made him master. The gay Sunflowers, the bright Rudbeckia speciosa with its deep yellow flowers relieved by their jetty central cones, and the Heleniums are in vivid contrast to the more sober hues of the Michaelmas Daisies, which range from white to deepest purple. The massive Tritomas, pride of the autumn garden, withhold not their lively colour from the view, while humbler but not less beautiful plants attract the many who seek a lowlier type of beauty. There are few things more delightful to the lover of the modest beauty of our alpine plants than the Saxifrages, which are now of the brightest or deepest green or of the finest grey, as their nature may be.

CALCEOLARIA PINNATA.

Very bright also, and attracting much attention from the many who have never seen it before, has been that pretty *Calceolaria pinnata*, the Pinnate or Wing-leaved Slipperwort, a native of Peru, and introduced in 1773. Although only an annual it is a perfectly hardy one, and sows itself freely; indeed, once fairly introduced no garden need ever be without it. I picked up a plant some years ago in a garden where it had been for a considerable time and as it was late in the season, potted it and placed it in my greenhouse. Here it seeded freely, and its progeny with their descendants have never left the greenhouse without a considerable number of representatives of the race. In spring some young plants were hardened off and planted out, and now there is stock enough outside. It is growing best in a half-shaded position in peaty soil.

Although the normal height of *C. pinnata* is only said to be about 9 inches I have it from 12 up to 26 inches in height, the bright yellow small and pretty flowers ranging from about half-inch to five-eighths inch in diameter. The foliage is deep green, thickish and pinnate in character. Is there not here a plant for the energies of the florist, who might by its means supplant the bedding *Calceolaria* of the day by a hardy annual?

SWEET PEAS.

We, who admire our perennial flowers, must beware lest we should despise the annuals which, in many cases, are of the utmost value in the hardy flower garden. What, for instance, could we do without the Sweet Peas, although we have a considerable number of perennial *Lathyruses* in cultivation? These Sweet Peas, which as Keats says are—

" . . . on tiptoe for a flight :
With wings of gentle flush o'er delicate white,
And taper fingers catching at all things,
To bind them all about with tiny rings."

may be over for the season, but they have done yeoman service when cut flowers are required, sparing often those needed to brighten the borders.

Of the new varieties raised by Mr. Eckford, Mr. Laxton, and others, it is impossible to speak too highly, and the lover of flowers cannot but feel deeply how much we are indebted to those florists for so enriching our gardens.

The annual Cornflowers, too, how useful they are! and I am sorry I cannot congratulate the raisers of the new double varieties upon the results of their labour. A greater variety of colours and markings has undoubtedly been secured, but this has been achieved at the expense of the grace and lightness of form of the older Cornflowers. None of these newer sorts can compare in value with the old blue or with one or two of the whites. There are some plants among the perennial *Centaureas* well worthy of notice, and I had intended noticing some of these, but, like the autumn Crocuses, this notice must be withheld for a time.—S. ARNOTT.

ANOMATHECA CRUENTA.

THIS plant is widely known and of easy culture. It is quite hardy in the south of England, and it will even survive ordinary winters some distance north if a sheltered position be chosen or protection be afforded when necessary. The plant is not very particular as to the kind of soil, though it should be preferably light, and in all cases well drained.

Some practise lifting and storing the bulbs in late autumn, and if the situation is very wet this is judicious and prevents some losses; otherwise, especially in warm localities, it is unnecessary. Still, some should be grown in pots, as very attractive and useful specimens for a cool house can be obtained with little trouble. Light turfy loam and peat, with a good proportion of sand, will suit them well under such conditions; and as growth is advancing an occasional supply of weak liquid manure will be advantageous, improving the flowers both in size and colour.

One bulb in a small pot, or several in a large one, according to the size, will be needed; and as the plants are rather tall in growth, reaching and even sometimes exceeding 2 feet in height, a light stake may be employed to keep the stems in position. This, too, is

generally needed in the open border, as they are very liable to be broken by wind or beaten down by rain if some similar precaution is not taken. In planting it is well to avoid placing the bulbs too deep, as that is likely to result in weak and imperfect growth. Three or four inches beneath the surface of the soil will be quite sufficient.

The plant is of slender and graceful habit; the leaves are about half an inch broad, tapering somewhat like *Ixias* and other similar plants. The flowers have each a long tube and six elliptical divisions, bright red in colour, with a tinge of scarlet; the three lower divisions are broader than the others, and have a dark blotch at the base. Though individually they do not last long, the scapes are produced in constant

FIG. 52.—ANOMATHECA CRUENTA.

succession during the greater part of summer, and even as late as September.

The accompanying woodcut (fig. 52) is a representation of this pretty bulbous plant.

IMPROVING SANDY SOILS.

GOOD loams are without doubt the best for all purposes, being intermediate between clays and sand. Soils that contain 30 to 50 per cent. of clay and 50 to 70 per cent. of sand should, if well drained, be moderately dry and warm, fairly easy to work, productive, and maintain under good culture their fertility. The position and locality being suitable, very often the soil is blamed for failures when the position of the land and the locality in which it is situated are unfavourable to the growth of particular plants or crops. We are not, however, dealing with the geological or geographical distribution of soils, but their improvement. When we have soils that contain 10 to 20 per cent. of clay and 80 to 90 per cent. of sand, considerable care in management is needed if fairly good crops are to result. This can only be accomplished by a thorough improvement of the soil, so that its fertility is increased, and this in many cases is not the work of a solitary season, often taking years to accomplish. Whether rapid improvements can be made at a trifling cost depends largely upon the materials necessary, whether they are close to hand for the purpose or the reverse. The absorbing power of the soil must first be increased, for it should be remembered that sand

possess the power of absorbing moisture from the atmosphere in a very small degree; for instance, "1000 lbs. of sand exposed twelve hours at night absorbed only 1½ lb. of water, while the same quantity of loam absorbed 20 lbs." This is not all, for the rains that fall upon such soils are not retained for any length of time to be a permanent benefit to the plants or crop, as they pass away beyond the reach of the roots too rapidly. The importance of increasing the absorbing power of these soils is therefore apparent.

Soils of the nature we are considering have little or no power of holding or fixing the fertilising ingredients of manure. This difficulty is overcome just in proportion as the absorbing power of the soil is increased. It is unnecessary to turn up these soils to the action of the weather because they do not need exposure to break them up and render them lighter and easier to work in spring. I do not advise turning them up for the winter until they have been materially improved and the absorbing power of the soil increased. Mineral matters may be acted upon by the weather and rendered soluble, only to be carried away by heavy rains, which, instead of adding to the fertility, certainly decreases it.

Sandy soils are quickly improved in both their chemical as well as their mechanical properties if good dressings of clay or marl can be spread upon the surface during the autumn and winter. These, when acted upon by rain, frost, and thaws, crumble to a fine powder, and quickly improve the texture of the soil. If clay is to be thoroughly incorporated with the sand it must be reduced to a powder. Where abundance of clay is handy, 100 cartloads per acre would be none too much, and this quantity would change in a solitary season the character of the soil. If fruit trees are to succeed on sandy soils, at least 1 inch depth of clay should be exposed on the stations where the trees are to be planted, the intermediate spaces can be improved at a more gradual rate. Again, if sandy soils require lime, a liberal dressing of clay or marl is of more value than a good dressing of manure. We certainly prefer the clay on these soils in preference to manure, and should only supply just what was really necessary of the latter for the production of a crop. There can be no doubt that when good marl is obtainable, and it contains say, 10 per cent. of lime, it is the best and safest method of adding lime to the soil. Marls, as a rule, contain some silica in a soluble form and phosphoric acid. When these are present the value of a dressing is certainly increased.

Clays and marls are not, however, within the reach of all who have to deal with sandy soils, therefore other measures must be adopted. In gardens of any pretensions where light soils have to be dealt with, the work of improvement can be rapid, because large heaps of vegetable refuse can be collected annually. The roots and stems of various plants, fallen leaves, the mowings of lawns, the edgings of walks, refuse from the potting shed, the surface material removed from Vine and other borders mixed together, soon form a large and valuable heap for the improvement of sandy soils. Many are very limited in this respect, and have to fall back on more natural means for changing the character of these soils. It is wonderful even under these conditions how quickly this can be accomplished, and fairly good crops produced. But to effect a thorough change it is the work of perseverance for years. Under these circumstances the only means to follow is to turn in every scrap of vegetable refuse that comes to hand, even the stems of Cabbage and Potato haulms.

In addition to this, some quick-growing plant must be sown at once after a crop has been removed. Nothing is better than White Mustard. Turnips, Spinach, and Rape may be also employed. The first is the best, because it grows rapidly, and not only yields abundance of material for turning in, but once sown will grow without attention, and will smother all weeds. To sow Mustard thickly and keep it from seeding is a method that cannot well be ignored for cleaning a piece of foul land. Very often two crops of Mustard can be obtained for turning in on the same piece of ground where early crops have been grown. On land from which Potatoes are lifted during the close of August and early part of September a crop of Mustard a foot or more in height can readily be produced. We have sown as late as the end of the month even in the north, and had a capital crop for turning in. If a crop has been grown strong and attained several feet in height, to prevent it seeding it can be chopped down and allowed to lie on the surface to decay until it can be dug in. Where only one crop is to be obtained it is better left on the surface than dug in too early. If manure is plentiful we should certainly manure freely even for Mustard, using the manure in a state that will afterwards be advised for light soils. The manurial ingredients would quickly be absorbed by the Mustard, and stored up in its roots and stems to be rendered available the following season for the crop that occupies the ground. No loss would take place by this method of procedure; on the contrary, the land would eventually gain considerably. Plant food that might, through the soil being idle for a few months, be washed away would be stored up by this "catch crop," if we may use the term, for the succeeding one. Green crops that are sown early for digging in should, so far as practicable where early and moderately early cropping is needed the following season, be turned under before the winter. Decomposition is slow when the soil is of a low temperature.

If the crop, whatever it may be, is to utilise the plant food placed in the soil in the form of manure it should be in the opposite condition to that applied to heavy clay soils. It ought to be thoroughly fermented (decomposed) before it is applied. Care must also be taken not to apply the manure before it is time to sow the seeds or plant the crop. If the manure is applied some time before the ground is cropped, the

same as would be perfectly safe on loams, the ready available plant food of the manure—such as the soluble salts of potash, soda, nitrogen, phosphoric acid, &c.—may be carried away by heavy rains altogether, or at least below the reach of the roots of the crop grown. No doubt considerable loss takes place under any circumstances—that cannot well be avoided, but by care this loss can be minimised as much as possible. We have reaped the best of results when the manure has been applied at the same time as the crop, the ground having been previously dug and the manure merely forked into the surface.

Sandy soils are less expensive to work than heavy almost unworkable clays are easier to improve. In the one case material is needed to lighten it, and in the other the reverse. Material is required to increase the adhesive properties of sands, so as to give them the power of holding and fixing plant food, instead of allowing it to be washed away or escape in the form of gases.—WM. BARDNEY.

ANTI-BLIGHT AND THE POTATO DISEASE.

THE following report of some experiments with Messrs. Tait and Buchanan's Anti-Blight powder has been sent to us for publication:—The Land Commission in Ireland last year made experiments with this powder, but with small success, as the proper implement for distributing it was not forthcoming at the time, and only hand-puffers could be used, entailing much labour and waste. Mr. W. A. Barnes, Westland, Kells, made a favourable report showing that two dressings of the powder gave an increase of sound tubers 31 per cent. over the undressed, while that which had received one dressing after the appearance of the disease gave an increase of 9½ per cent. Other experimenters found that they could not apply the powder properly with the machines supplied, and turned their attention to the *Boullie Bourdelaise*, distributed by the "Eclair" sprayer, but from the report of the Irish Land Commission there was no satisfactory evidence of a cure by this treatment. The same report states that the powder would probably produce the best results if applied two or three times in small quantities. This can be done by the use of the Torpille knapsack, carrying enough of the powder to dress two acres (24 lbs). During the present season some fresh experiments are being made with the powder, of which as yet only two reports are to hand. One is from the Home Farm, Carlung, West Kilbride, where two roods were experimented on, the Potato planted being a fine variety of Maincrop from the Lothians. One rood dressed with Anti-Blight by the Torpille on three several occasions (June 9th, July 1st, and July 25th), dug on 13th October, yielded:—

Dressed.						Undressed.					
Tons. cwt. qr.						Tons. cwt. qr.					
2	6	2	good	2	4	3	good
0	2	0	small	0	2	0	small
2	8	2				2	6	3			
Produce per acre, 9 tons 14 cwt.						9 tons 7 cwt.					

Gain per acre, 7 cwt.; value, 21s. Cost of Anti-Blight used in three dressings:—

	s.	d.
9 lbs. to 1 rood (=36 lbs. per acre), value	...	7 9
Labour for 1 acre (3 days, 1s. per day)	3 0
		10 9

(N.B.—The time taken to dress 1 rood not more than 2½ hours, and easily done by a young boy or girl). The above half-acre showed no disease to speak of. A blighting wind about the end of July killed down the haulms completely, after which there was no growth; otherwise a fourth and even a fifth dressing would have been given had disease shown itself. The other report is from a cottage garden at Fairlie, where ½ pole was dressed three times by a Malbec bellows, during June and July, dug 14th October, yielded:—

	Tons. cwt. qr. lb.			
63½ lbs. good, sound tubers—average per acre ...	9	1	1	20
9 lbs. small and diseased tubers—average per acre ...	1	5	2	24
	10	7	0	16

Percentage diseased, 12.41.

This ground has always been much infested by disease, but another patch of same variety thought to be more favourably situated, was left undressed, and yielded:—

	Tons. cwt. qr. lb.			
25 lbs. good, sound tubers—average per acre ...	2	10	0	0
50 lbs. diseased, bad tubers—average per acre	7	2	3	12
	9	12	3	12

Percentage diseased, 66.5.

The same blighting wind as described in the previous experiment stripped the leaves and withered the haulms of all the Potatoes around the place, and Potatoes on all sides have been much diseased. We have just seen results of a trial of the powder carried out by Mr. John Speir,

Newton Farm, on a portion of a field of Myatt's Kidneys. Some shaws lifted from three different parts of the dressed portion of the field showed 11.23 per cent. diseased. Other shaws lifted from three different parts of the undressed portion of the field showed 19.04 per cent. diseased. Mr. Speir calculates the labour and powder used in the repeated application as 10s. 6d. or less per acre.

ROYAL HORTICULTURAL SOCIETY.

OCTOBER 18TH.

SCIENTIFIC COMMITTEE.—Present: Dr. M. T. Masters (in the chair). Mr. Morris, Mr. Blandford, Prof. Church, Dr. Scott, Rev. W. Wilks, Dr. Müller, Dr. Russell, Rev. G. Henslow, Hon. Sec.; and Mr. J. Carruthers, visitor.

Bouillie bordelaise.—A communication was received by Mr. Blandford from Mr. E. D. Till, The Priory, Eynsford, Kent, stating that of twenty-six experiments in gardens, fields, and allotments, on different sorts of Potatoes this season, they were all completely successful. The mixture used consisted of 1 lb. of copper sulphate, 1 lb. of freshly slaked lime, 1 lb. of syrup, and 5 gallons of water. The following are some of the more striking results selected from Mr. Till's report: "Early Puritan," once, twice and thrice syringed respectively, all were good; the haulm being green four weeks after the others had decayed. When not syringed 25 per cent. were bad. 'Wilford Park,' considered a good disease resister; of seven rows not syringed 5 per cent. only were bad. Of a row twice syringed all were good, cleaner, and of a more regular size than the others. Of 'Sutton's Abundance,' 20 to 25 per cent., 'Victory,' 20 per cent., and 'Chancellor,' 3 per cent., were bad when not syringed. 'Reading Giant,' when twice syringed, were all good, with more than a fourth excess of crop; all being cleaner and of a more regular size than in the rest of the field, where it gave an average crop. The haulm was green to September 25th, six weeks after the others had decayed. Of seven varieties grown on allotments, of 'Snowdrop' twice syringed, all were good; once syringed, eight tubers, bad; not syringed, sixteen bad. Of 'Early Puritan,' twice syringed, twenty-five tubers bad; about sixty being bad on two adjacent rows not syringed. In a garden, 'Beauty of Hebron,' once syringed, all were good and very clean; while of two rows not syringed 30 per cent. were bad." Mr. Till concludes his report with the following general remarks:—"The leaves were very thoroughly syringed on both surfaces, and at a date (July 1st, 15th, or 20th to 23rd) when growth had nearly attained its full development. The quantity applied at the rate of about 350 gallons per acre. The most striking results were on the early sorts. The later sorts were freer from the disease. The 'Reading Giant' plot showed a largely increased quantity in comparison with the adjoining rows, while the superior size, regularity, and quality were very marked. Also the 'Ware,' or selling sizes, were very much more regular. This was no doubt due to the haulm being kept in vigour for five to six weeks after the rest of the haulm in the field had withered. There is no mistake about the great advantage of the solution when applied to this variety; improved growth was not so marked in other sorts, though certainly very noticeable generally." Prof. Church remarked that the use of the syrup was to make the hydrated oxide of copper more adhesive to the leaves, and he observed that dextrine had been used in conjunction with sulphuretted mixtures for Roses and Chrysanthemums; but the special value of sugar was that it entered into combination with the lime, and was subsequently set free, retaining all its adhesive properties. Mr. Blandford added that the use of sugar had been adopted as the best result from a large series of experiments carried out in France.

Docks Attacked by Grubs.—Dr. Masters received a communication from Perthshire together with specimens of grubs which had attacked some Docks. As *Rhubarb* was about to be placed on the same ground, being of the same family (*Polygonaceæ*), it was thought the latter might be attacked also. It proved to be the "Ghost Swift," *Hepialus humuli*; but, as Mr. Blandford observed, this insect is so very generally distributed that no remedy could be suggested other than the destroying the plants with the grubs as much as possible.

Walnuts Imperfect.—Mr. Noble sent specimens of Walnuts, in which the shell was imperfectly developed in certain places, though the kernels appeared to be sound. It was suggested that the cause might be defective root action from a clay soil, or perhaps the sharp frost in June when they were very young.

Fog Report.—Some discussion arose as to the desirability of recommending observations on the injuries to plants by fog during the coming winter and pursuing them in a systematic way. It is proposed, therefore, to reconsider the programme drawn up in 1891 at the next meeting of the Scientific Committee, especially in its bearings on the best practical methods of resisting the injuries of fogs in the construction or adaptation of plant houses or otherwise.

Peat-wood.—Dr. Russell showed some specimens of wood from a peat bed of a few feet in thickness on Dartmoor, in Devonshire, where there are no trees at the present time. One was that of Birch, but the other was not recognisable on inspection. It was referred to Kew for comparison with some museum specimens.

Fasciate Holly.—Mr. G. Paul sent boughs of *Ilex Donningtonensis* with this peculiarity. It appears to be a variety particularly liable to fasciation. The cause of fasciation is still unknown among trees. It is particularly common in the Ash and Cotoneaster.

Cunonia capensis.—Flowering sprays of this shrub were sent by

Mr. Burbidge. He observes that it is an old plant, but not often to be seen in gardens at the present time.

Pelargonium Sport.—A new double variety was received from Mr. Cannell called 'Double New Life,' having the peculiarity of the petals being white, red, and flaked in the same blossom. It originated from a double *Vesuvius* called 'Wonderful.' A flaked variety of the single *Vesuvius* appeared in the Isle of Wight in 1888. It has also sported to a salmon colour, as well as white, several times. The leaves are peculiar in having acquired almost a purple tint. The original *Vesuvius* was raised by Messrs. A. & F. Smith of Dulwich in 1868.

Egyptian Figs.—Mr. Henslow exhibited an instrument used in Egypt for cutting off the tops of the nearly ripe fruit of the *Sycamore Fig*. It consists of a circular strip of iron, one edge being sharpened, and inserted like a loop at the end of a stick. The object is to allow the insects to escape (*Sycophaga crassipes*, *Westw.*), which always infest that species. The *Sycamore* is never propagated by seeds in Egypt. The custom is apparently very ancient, and the Hebrew word translated "cultivator" as applied to the prophet Amos (ch. vii., 14) really signifies "scraper," as correctly given in the Septuagint version (written at Alexandria). It is described by Theophrastus and Pliny, but no mention is made of the insects. As the fruit becomes sweeter it was thought to ripen them.

FRUIT FORCING.

Figs.—*Early Forced Trees in Pots*.—Trees that are to be started gently about the middle of November to afford a supply of ripe fruit at the close of April or early in May will now need to have the wood brushed over, using softsoap, 4 ozs. dissolved in a gallon of boiling water, and when cooled to 120° apply with a brush, reaching well into every angle, so as to dislodge any scale or hibernating red spider. Very little pruning will be required if the trees have been carefully and regularly pinched during the growing season, but if the growths are irregular or too crowded they must be shortened and thinned to render the trees symmetrical and fruitful. Wash the woodwork and walls with scalding water after clearing out every particle of the fermenting material or beds. Limewash the walls, adding a handful of flowers of sulphur to each pailful of limewash. Then dress the trees with a mixture of softsoap and sulphur, 4 ozs. of softsoap to a gallon of boiling water, adding enough sulphur to form a cream, using a brush and reaching every part, being careful not to rub off the embryonic Figs, nor to injure the shoots, as those of the current year are very brittle. A mild bottom heat is almost a necessity to a successful swelling and ripening of the earliest crop; but the pots, unless small, must not be plunged in the fermenting beds, or they will sink with it and be subjected to checks in raising the fermenting material. Provide, therefore, pedestals of loose bricks on which to stand the pots, so that their rims will be a little higher than the pit edge, and the pit can then be filled with Oak or Beech leaves pressed down firmly. If the pit is not more than 3 feet deep, a third of stable litter may be added, and the leaves and litter should be thrown together in a heap, moistened if necessary, and turned once or twice so as to thoroughly mix them and induce gentle fermentation. Overheating must be avoided, the heat in the early stages never exceeding 70° to 75° at the base of the pots, nor more than 60° to 65° about them until growth takes place. If trees have to be purchased, select those with single stems, and such as have not been hard second-cropped, thoroughly ripe in the wood, and having Fig buds in evidence of cropping. The large fruits will not come to anything; it is the small rounded fruit or buds that give the first crop. The trees may be potted if they require a shift, but let it be small; in fact it is wisest to merely cut off the drainage portion of the ball, loosen the soil a little at the sides, and remove the loose surface soil, shortening any straggling roots, and return to the same size of pot or such as will admit of a little fresh soil under, around, and over the ball, all pressed as firmly as possible. Figs like a calcareous soil, say three parts yellow fibrous loam, one part old mortar rubbish, one part road scrapings, and one part decayed stable manure, with a 9-inch potful of half-inch crushed bones to 3 bushels of the compost, and a similar proportion of charcoal, all well mixed. Suitable varieties for early forcing are *St. John's* (Tresfer), *Early Violet*, and *Angélique* (Madeleine). *Black Provence* and *White Ischia*, are also suitable, have small fruit, *Angélique* being medium size, and bear heavy first and second crops, without prejudice to succeeding year's crop. *White Marseilles* and *Brown Turkey* (Dwarf Prolific and Lee's Perpetual) are unequalled for forcing so as to produce fruit from trees in pots in late April or early in May, and they are large and good in flavour.

Early Forced Planted Trees.—Trees planted in borders and intended for affording ripe fruit at the end of May or early in June, they being started at the new year, must now be untied from the trellis and pruned. Those restricted at the roots to small borders in a firm condition will, from their short-jointed and sturdy growths, require little more in the shape of pruning than thinning out the shoots where too crowded and

cutting away the parts which have reached the extremities of the trellis and become bare of fruitful wood. Those not having the roots restricted will require hard pruning at the upper part of the trellis, allowing room for the growth of the successional branches; but severe pruning only induces stronger and less fruitful growths. Such trees should be lifted, and have the roots confined to narrower well-drained borders of firm soil. Remove the surface soil down to the roots, pick out the old soil from amongst them carefully, and supply a top-dressing of fresh loam with some old mortar rubbish intermixed. Ventilate fully at all times, except when frost prevails, and at such times heat should only be used to exclude it, though the trees will not take any harm unless the weather is very severe.

Succession Houses.—When the leaves have fallen prune the trees and well wash them with a soapy solution, using a brush, which will do much to dislodge the insects, and after the woodwork and walls have been scalded with hot water, keeping it off the trees, the latter may be dressed with an insecticide, and the walls limewashed. Complete any root-pruning, lifting and laying the roots in fresh compost. Fig trees with the roots restricted are more manageable and fruitful than those with an unlimited rooting area; therefore lift, and severely root-prune any unfruitful trees, and restrict the roots to moderate-sized borders, making the soil firm and employing good loam with a sixth of old mortar rubbish and a sixth of road scrapings, good drainage being paramount.

Late House.—The trees should have the wood cut out that has borne fruit and is no longer required, and any trees having a tendency to over-luxuriance or that cast their fruit instead of swelling off should be lifted and have the roots confined to borders of limited extent. When the leaves fall the trees must be unloosened from the trellis, and being tied together they should be made safe against frost by placing a little hay or straw amongst them and covering them with the latter or mats, for trees in cool houses suffer nearly as much from frost as those against walls outdoors. The roots near the collar are better with a slight protection of dry material.

Peaches and Nectarines.—*Early Forced Trees.*—Where the supply of fruit in late April or early in May is had from trees of Royal George and Stirling Castle Peaches, with Lord Napier and Stanwick Elruge Nectarines, forcing must commence in earnest at the beginning of December, the house being closed at the middle of November, but no fire heat need be used in the first fortnight beyond that necessary to exclude frost. The trees, therefore, must be got into proper order without delay, not, however, putting on the lights to make things comfortable, as they are better off until the time stated, and there are favourable opportunities for attending to the necessary work, though it is better done as soon as the trees become leafless.

Succession Houses.—When the leaves are all down, there not being any forcible means taken to secure that end until they part freely from the trees, unfasten the latter from the trellis, and prune them; also thoroughly cleanse the house, paint the woodwork and trellis, limewash the walls, and after washing the trees with soapy water and following with an insecticide, secure them to the trellis, leaving room for the branches to swell, as tight-tying is one of the most prolific sources of gumming. Clear away the loose surface soil or mulching, pick some of the old from amongst the roots, and supply fresh rather stiff loam, with a quart of steamed bonemeal to every three bushels, and add about two quarts of wood ashes to the same. The advertised fertilisers may be used in similar proportions. If the roof lights are not moveable, give a thorough supply of water to the inside borders, and do not allow them to become dry during the rest season, ventilating fully. It is better, however, to remove the roof lights, let the rain cleanse and refresh the trees, moisten and enrich the soil through to the drainage. Attend to any lifting, or the introduction of fresh trees, as this work and root-pruning should be performed before the leaves have dropped, yet the wood ripe and the buds plumped. Trees for planting in houses are best two or three years trained to walls, and, lifted in the preceding year, they transplant with an abundance of fibres, and can be forced very well the first year if not started before the new year, not brought on too rapidly, and not overcropped. Trees, however, that have been grown under glass have the wood better ripened, and are more suitable for early forcing. If young trees must be planted, select such as have no trace of gum, but are clean in growth, not very strong in the wood, shapely and well but not over-furnished with branches. The sooner they are planted after they are in a fit condition the better, so that they may become somewhat acclimatised.

Late Houses.—Salwey is sometimes fairly juicy, and not always more woolly than fleshy, yet it is only a sorrowful fruit after the juicy and rich Gladstone Peach. This seems to be just as good in October as in September, and it certainly gets bigger and better with cultivation. Cut out non-extension wood that has borne fruit as well as any other growths not required, as this lets daylight reach those that are left, and nothing is so prejudicial as too much wood in late houses. Any trees that are not ripening the wood well will be induced to do so by forming a trench about one-third the distance from the stem the trees cover in height of trellis and down to the drainage, so as to detach the roots. Do not allow the foliage to flag severely, but supply water if necessary to the part inside the trench, and let that remain open about a fortnight, then remove the surface soil down to the roots in the undisturbed part; pick out the soil from amongst them, supply fresh loam, fill up the trench, make all firm, and give a good watering. The trees will push fresh roots, plump the buds, and the blossoms from them invariably set well, whilst the fruit is rarely cast in stoning.

THE KITCHEN GARDEN.

Asparagus.—The tops of these have now in most cases done their work, and are quite brown enough to be cut and burnt. Whether mown with an old scythe or cut with hook or a knife avoid stubbing them down too closely to the ground, a length of 6 inches of stem above the soil denoting the whereabouts of, and, it may be, saving many crowns from being forked into or trampled upon. Weeds are frequently too abundant among Asparagus, especially where no heavy mulching material is used. These must be cleared off by hand-weeding, and not hoed up or dug in. Select a dry day for this work, and well shake the soil from the roots of the weeds, or otherwise far too much of it will find its way to the rubbish heap. Seed pods are very abundant, and if a few of the strongest growths well furnished with these are hung in a dry shed abundance of excellent seed can be rubbed out when wanted next March or April. New seed always germinates the most quickly and strongly. Forcing of Asparagus may commence now, but the young growths obtained in November or very early in December are not nearly so good as they would have been had the crowns been allowed a longer rest. Only those, therefore, with an unlimited supply of strong old roots ought to commence forcing as yet.

Manuring Asparagus Beds.—Autumn manuring is practised with very satisfactory results in many cases, but is far from being generally safe or advisable. It may easily do more harm than good. A heavy surfacing of half-decayed manure may be beneficial where the soil is of a light or non-retentive character, but it has been the means of destroying thousands of crowns where the soil and subsoil is of a clayey nature. Asparagus, if the roots are not actually exposed, is perfectly hardy, but it cannot survive several months together in a cold retentive soil. Mulching a bed with decaying manure serves to keep the soil unduly moist and cold, the spring finding it in a saturated pasty state. Let heavy soils have the benefit of all the frosts, winds, and sunshine going, and it will then be found in a comparatively warm friable condition next spring. Being undisturbed the rains will pass away freely, some running off the surface and still more through the drainage holes made by worms, whereas loosened surfaces absorb nearly all the rain and snow water that falls. If the beds are manured now avoid chopping down the sides, as this is most destructive to the roots. Only what may be raked off the surface should be thrown back over the manure, the sides being left intact and the paths or alleys undug, many active roots invariably being found in the latter.

Beet.—A severe frost completely spoils any roots of these not protected, and no further risks ought, therefore, to be run. In lifting do not drag out the roots, but carefully raise with forks, thereby avoiding breaking the tap roots, as these when broken are apt to bleed, a loss of colour being the inevitable consequence. The tops should be screwed off and not cut, and after clearing them of the worst of the soil clinging to them either store the roots in a cool shed or cellar or else place in a cone-shaped heap in a cool dry spot where rats and mice would not be likely to get at them. They shrivel badly in dry hot positions, but will keep well in a cool shed if packed in sand or fine soil, crowns outwards, an additional covering of mats or litter being afforded during the prevalence of severe frosts. Those stored outside in a heap should be covered with dry straw, and then heavily soiled over much as Potatoes are sometimes stored. The coarsest roots of the larger varieties are not appreciated by good cooks, and these should go to the pigs. Turnip-rooted forms keep fairly well, but if roots of a long-rooted variety are plentiful use the former first.

Carrots.—These also ought to be lifted and stored. Raise them with forks, throw all the badly cracked roots on one side for horses to eat, clear those selected of heavy soil, and cut off the tops an inch away from the crowns. They may be stored either in cool sheds, in sand, or in heaps outside, and protected as advised in the case of Beet. Late sown Carrots have grown rather more strongly than desirable, many of the roots being larger than are appreciated by those who like to have sweet young roots served whole as a vegetable. These should only be drawn as required for use, thinning out being practised, as the smaller ones left usually improve in size during the winter. Frosts rarely injure late sown Carrots, slugs and grubs being the worst enemies the cultivator has to contend with. A light surfacing of wood ashes, or failing this soot, the dressing being stirred in with a Dutch hoe, may help to keep such pests in check.

Other Root Crops.—Jerusalem Artichokes are perfectly hardy, and keep much the best when left undisturbed where they are grown. If severe frosts are anticipated cover a portion of the bed with a good thickness of strawy litter, and the roots can then be lifted during the coldest weather. The roots of Celeriac, or Turnip-rooted Celery, are far from being hardy, and should, therefore, be either heavily banked over with soil or else be lifted, have the tops trimmed off, and be then stored very much as advised in the case of Beet. Salsafy and Scorzonera roots are quite hardy, and also keep much the best in other respects when left where they are and dug as wanted for use. A portion of the rows being banked up with strawy litter, the roots can be dug during the prevalence of the severest frosts. Chicory, on the other hand, is not so hardy as desirable, and it is advisable to lift and store the roots, crown outwards, much as Carrots are treated. A few dozen of them can then be introduced into the Mushroom or other warm quarters, where the tops will grow quickly and blanch thoroughly. Treat Parsnips exactly as advised in the case of Artichokes, it being a great mistake to lift and store these. Turnips, especially if rather large, cannot be depended upon to pass safely through the winter where they now are,

and in order to be on the safe side with this important root pull and store at least a portion of the crop. They keep very well if trimmed and stored similarly to Potatoes, the heaps being examined occasionally and all sprouts rubbed off the roots. Chirk Castle Black Stone is the hardiest variety, Orange Jelly also standing well through most winters. The latest sown, and which have failed to "bulb" properly, ought to be left where they are, as these may produce an acceptable crop of greens. Leeks are perfectly hardy, and continue to increase in size whenever the weather is mild.

PLANT HOUSES.

Allamandas.—These will continue to flower for some weeks longer, provided they are liberally supplied with stimulants. Plants grown in pots will be crowded with roots, and a dressing of decayed manure on the surface will help them to develop their flowers; in addition to liquid manure frequently, artificials may be applied to the surface. If the plants are not well supplied with food the flowers will be small and only poorly developed. Growths that have done flowering should be thinned out, so that the energy of the plants may be devoted to the development of the flower buds that are formed. Light will also be admitted to the occupants beneath and also to the flowers, which will be of a brighter colour.

Gesneras.—Be careful not to water these on their foliage or they will be browned and disfigured. At this period of the year until they come into flower they do best on a shelf fairly close to the glass, where a good heat and a fair amount of moisture is maintained. Give these plants clear soot water every time they need water. Be careful not to allow them to become dry; on the other hand, they should not be kept wet.

Tydaes.—Those that are coming into flower may be removed to the stove proper, but they should have the driest position or else the foliage will damp. The remaining portion of the stock may be given the treatment advised for Gesneras. Spring-flowering kinds of the Madame Heine type that do not make underground stems may have a temperature of about 60°. These do best standing on some moisture-holding material.

Crotons.—Plants that are needed for room decoration should be given slightly cooler treatment than the main stock of Crotons. When well hardened these plants last in such positions for a very much longer period of time; in fact, double the length of time than when removed from a close moist structure where a high temperature is maintained. Growth should now be complete and no attempt must be made to force these plants to grow. Young leaves made at this season rarely colour, and if used in rooms before these are developed they invariably flag and frequently fall off.

Acalyphas.—Plants grown for winter decoration in rooms should not be kept too warm, or they will continue to grow and the young leaves flag when removed to cooler and more draughty quarters. These plants should occupy an intermediate structure where air can be given daily. This not only prevents further growth but hardens the plants so that they bear room decoration fairly well for a time without losing their foliage. For the conservatory in summer these plants will in future replace Coleus altogether. When properly grown for this purpose they stand well and are much more effective, being choicer in appearance than Coleus. Plants that have become shabby may be cut down and placed in heat to break. Keep them on the dry side at first or the roots will perish.

Poinsettias.—The earliest batch will have commenced to show their bracts, and these may have a temperature of 65°. The plants, if strong and well grown, will develop large bracts in this temperature. Keep them as near the glass as possible; on this depends whether the bracts are brilliant in colour or the reverse. Feed with weak stimulants every time water is needed. Later batches should be kept at 60° with a little air daily until growth is completed, when the temperature may be raised. If kept too warm before the completion of growth the plants often start growing, and only poor bracts are produced.

Euphorbia jacquiniæflora.—Keep plants at 55° to 60° until they display their flower buds; if the growths have not been well ripened and are kept too warm they will start into growth instead of flowering. Once they do this all chance of their blooming satisfactorily is over. Do not overwater these plants, for they are very liable to go off at their roots if kept too wet. *Justicia flavicoma*, not yet showing flower, may have the same treatment. Plants that are showing flower may be brought into bloom in the temperature advised.

Celosias.—Plants that have been kept in a temperature of 55° to 60° to bring them into flower should be carefully and gradually hardened before they are placed in the conservatory. When forced out in heat and removed direct to a lower temperature they are liable to damp off just above the soil. When care is taken to harden them they should be watered judiciously and then they will last a long time.

APIARIAN NOTES.

NEVER in all my experience has the work of the apiary been so long delayed as during the present autumn. Many apiaries still remain as the hives were brought from the Heather, and many to feed yet. My own have all been finished and fed as required for more than a week now; but should a favourable day occur between this and the middle of November, I shall give all a feed. This is very good for bees at the beginning of winter, encouraging them to fly out and clean themselves thoroughly, by which they are enabled to withstand a protracted winter.

NARROW DOORWAYS.

Every one of my hives have their doorways contracted to three-quarters of an inch, and I shall allow them to remain so until the bees in spring show a desire to have them widened. Should they take an airing any day during winter I may widen them until their flight is past, then close again.

WINTER PRESERVATION OF BEES.

This has been long studied, and is still a problem to many bee-keepers; but in my own apiary that has been many years solved. It is now thirty years or more since I wrote to the *Cottage Gardener*, explaining my method of insensible upward ventilation, and Mr. G. M. Doolittle in "Gleanings" for October speaks of the system favourably. He says: "I adopted the plan as it was then termed, although I now look at it as practically no direct ventilation, unless you can call it ventilation which we have when sleeping under our warm comforters on a cold winter night." Precisely so. Just what I practised and taught so long since, and still continue to do so, because it is the only method we can successfully bring bees safely through winter.

Bees never die of old age. They only become worn out by much flying, or succumb at an early age to the rigours of a severe winter when located in hives having either a draught or dampness inside the hive. Youthful bees that have never flown and that were bred late in the fall, are those that die first and communicate disease through cold to the adult bees between November and February.

During my stay at the Heather I visited several batches of bees, numbering from twenty to forty hives in each lot. In one of the latter there was a division of 20 feet between two sets of hives. There was nothing else to distinguish or influence them in any way, all looking easterly towards the Heather, and within 20 feet of a field of Oats, sheltered behind by a stone dyke and a few trees. One batch had a good-sized swarm of dead bees in front of every hive besides what were lying scattered further beyond, and a number of them dead. In another lot in a line with them there was scarcely a dead bee to be seen. In the last named the entrances were less wide and apparently better covered, while the former had very wide entrances and the ventilators opened. This was all the difference I could distinguish between the two lots, the hives being similar in all other respects.

In another batch of forty hives there were four better protected than the others, being well covered with felt, and the entrances were half the size of the others. These four hives lost very little weight, while all the others did, from 10 to 20 lbs. each.

STRONG HIVES.

I never had hives so full of bees as they are this autumn; in fact, more than I care for at this season. Too many consume much honey, and are unnecessary to carry on all the breeding required for swarms at the proper period; better, however, too many than too few. I hope for the best, and for better seasons than the one now closed. Strong hives at the present time are, or ought to be, the great desiderata of bee-keepers. One queen to one hive properly managed meets all the requirements of the majority of bee-keepers, but in some cases it is absolutely necessary to have the progeny of two queens in one hive.

Premising, then, that all have their hives in proper order to withstand the winter and survive the spring unscathed by extreme zero weather or internal dampness, and anxious to catch the first flow of honey, a proportion of hives must be sacrificed at not less than one month before the expected first honey yield. In another article I will explain how to accomplish this.—A LANARKSHIRE BEE-KEEPER.

* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Odontoglossum citrosimum not Flowering (C. R.).—No doubt your plants have had too much water, as this lovely Orchid is often spoiled in this way; the plants should be hung near the glass in the house they are in at present. When growth has finished they require no water for weeks together, and even when growth commences no water should be given until the spikes are several inches long. Do not be afraid to keep them dry while resting, then you may expect better results.

Plum Trees for a North Wall (Amateur).—As the Currants are not wanted Plums and Cherries may be grown. Morello Cherries would be more certain to bear and ripen well than dessert sorts, though we have no doubt good fruit might be had from these. All except the latest Plums would answer. We have had good crops of Czar, Victoria, White Magnum Bonum, Prince Englebert, Kirk's, Pond's Seedling, and Purple Gage, from trees against a wall facing due north, the second-named bearing most heavily. We should prefer covering the wall with diagonal cordons, planted about 18 or 20 inches apart. The space would be covered much more quickly than with fan-shaped trees, and the former are inexpensive.

Simple and Good Methods of Storing Apples (F. G. B.).—In many gardens there exists a collection of Apples, and, as in your case, no adequate provision made for storing the produce. Very frequently the crops are comparatively small, or, say, do not exceed a bushel of each variety. The best course to pursue with these is to gather and store each variety separately in quite clean boxes, which may be bought or made at a trifling cost. None but quite sound fruit are suitable for this method of storing, and these should be carefully gathered and placed direct in the boxes. The lids should be then put on and all be set in a dry room or outhouse, and protected from severe frost when necessary. Apples thus stored and left alone will keep surprisingly well.

Grafting Tea Roses (Rosa).—Grafting can be done at almost any time provided the stocks and scions are in suitable condition, but is generally delayed until after the turn of the year, as with increased light and heat from natural causes the plants then grow with vigour after the union is complete. Grafting usually commences in January, using wood in a dormant state or nearly so, and the stocks must be in the same condition. It is not necessary that the plants from which scions are taken should have flowered if you are certain that the varieties are true. The greatest success by a beginner would be attained by starting his plants from which the scions are to be taken in heat and the stocks also until the sap has commenced rising freely. The wood of the scion should be nearly half ripe; it should have, at any rate, a certain amount of solidity. It is not necessary to introduce the stocks into heat as early, the scions producing plants. Still, if you work any in a dormant state you may introduce the two together, and when the sap in both commences flowing grafting can be performed. One eye on each scion is ample. It will be necessary to have a close frame, the same as you would employ for propagating, to place them in after they are grafted, and if slight bottom heat can be given them all the better. This is especially necessary when moderately young wood is used for scions.

Gas Lime for Ground to be Cropped with Potatoes (R. B.).—We use gas lime on ground intended for Potatoes alike as a preventive of attack by vermin and fungi. It is from our own works, the gas being manufactured for lighting the mansion, stables, and the driving engine for pumping, consequently we have always got some available. The best time to apply it is, to ground to be cropped with Potatoes in October or November before the ground is dug or manured, and at the rate of half a bushel per rod (30½ square yards). It should be disposed as evenly as possible on the ground, and either lightly hoed or pointed in with a fork. At that time vermin and fungoid germs are on or near the surface, and more readily available for attack, and any injurious effect the gas lime may have passes off by exposure to the atmosphere; in fact, passes quickly into the gypsum state, in which it is not a despicable manure. After lying a month or so the ground is manured if necessary, the gas lime being buried in the work of forking or digging. In spring, before the Potatoes are planted,

we occasionally use the gas lime again, particularly for ground that has not previously or recently been dressed with it, at the same rate as in the autumn, spreading it evenly on the surface, and leaving it there for at least a month before "setting" the Potatoes. This, however, is only practised when the ground is foul with slugs, as the full application of gas lime—viz., 1 bushel per rod, should only be had recourse to when the soil, as shown by the attacks on the crops, is extremely foul. As to the beneficial effects of a dressing as a preventive of scab, we can only state that on some ground which three years ago gave scabbed crops, the Potatoes are this year free, the land having been consecutively cropped with them, which in this particular instance is a necessity. It is not, however, sound practice to follow Potatoes on ground that produce scabbed tubers, nor to use "seed" tubers that are scabbed or taken from an infected crop. Necessity, however, precludes choice, and it is not certain that the ground is at fault, as tubers show no trace of scab at lifting, but during the winter it develops, and they become much deteriorated in value, the quality being invariably good.

Preventing Disease in Tomatoes (S. S.).—When the white mould that you call mildew is seen on Tomato plants it is then too late to save that part of the leaf from destruction, for the "mould" is the out-growths from the mycelium of the fungus which has pushed through the cells of the leaf and abstracted their contents; in fact, destroyed the tissues, and the brown or black spot or patch appears in consequence of their death. The best way to avoid the Tomato disease, the "white mould" (*Phytophthora infestans*), is to maintain a warm but airy yet genial condition of the atmosphere, for the simple reason that the spores cannot germinate in a dry atmosphere; therefore the "white mould" is seldom seen in Tomato houses until the weather becomes warm and the atmosphere is laden with moisture. True, it makes its appearance sometimes early in the season because the moisture condenses on the leaves. The conidia of the fungus needs and must have this moisture to liberate the zoospores, and then is the time to prevent these finding a seat and pushing their germinal tubes through a stomate or weak part of the leaf into the internal tissues. If that is done there cannot be any white mould. The way to do it is as follows:—Dissolve 1½ oz. of carbonate of copper (precipitated) in a pint of liquid ammonia; of this one fluid ounce to 1½ gallon of water, mix, and spray (not syringe) every part of the plants, particularly the under side of the leaves, using no more than just sufficient to coat the leaves with the finest possible dew. This may be done just before the plants come into flower, again when the fruit is fairly set and swelling, and about the time the fruit is half swelled. The first two applications are usually effective, but if a third or more is needed it is necessary to have some oilskin bags made with a slot and string at the mouth to slip over the fruit and secure them around the fruitstalks by means of the string, so as to keep the solution from the fruit, taking them off when the plants have been sprayed and become dry. If the solution is found too strong, blackening the leaves, dilute to 3 gallons, and if any "white mould" appear cut off that part of the leaf or leaves and destroy by fire. This procedure requires care and judgment. When both are duly exercised the operations pay cent. per cent.

Pears Cracking (May).—The fruit you have sent is suffering from an attack of a fungus, *Cladosporium* (*Fusicladium*) *pyrinum*, *Fekl.*, a form of *Cladosporium dendriticum*, which causes "scab" in Apples. Certain varieties are peculiarly liable to injury from this fungus, also locality and soils exert an influence, for a variety will crack seriously in one part of a garden or orchard, whilst in another position the fruit will be clean. It is often found that lifting a Pear tree, subject to suffer from cracking in its fruit, and giving it some good top-spit loam, is effectual in warding off attacks of *Cladosporium*, and it must be distinctly understood that healthy trees are always the least liable to an attack. Attend, therefore, to those essentials that are known to promote health in the tree and clear skins in the fruit, that is, fortify them so that they form clean bark and thick leathery leaves. Aim at not strong and sappy, but medium, healthy, firm growth. Whatever, therefore, is wanting at the roots supply it. If the soil is wet, drain it; if too heavy, make it lighter, and *vice versa*; if the tree grows too luxuriantly, lift, root-prune, and replant it in firmer or less rich soil; if the tree is stunted, afford some manure of a sustaining nature; if the soil is exhausted, remove it, and supply fresh of a good holding nature; if there is a great show of blossom in spring, remove half or more, and thin the fruit. The scab fungus lives through the winter on the young shoots and upon the scales of the buds, and if the germs are killed before or during germination there cannot be any scab in Apples or cracking in Pears as occasioned by this fungus. First, in the early spring before the leaves appear, spray the tree with the preparation of sulphate of copper mentioned in the preceding reply, choosing a dry period and with a prospect of fine weather. Second, as soon as the petals have fallen, apply 1 oz. of carbonate of copper (precipitated) in suspension with 12½ gallons of water, first mixing the carbonate of copper in a small quantity of water, adding the mixture so formed to the water; keep it agitated whilst being applied as a spray, a knapsack pump doing it effectually. Third, repeat the application of carbonate of copper in suspension in fourteen to twenty-one days, and again at a similar interval in bad cases, but the three first dressings are usually effectual, a fourth only being required in wet seasons.

Planting Yews and Hollies (Amateur).—Some shrubs fail no matter when they are planted, through not being in proper condition for removal. We have seen hundreds of large shrubs purchased at a low price, the possessors having been not a little jubilant in getting

so much for their money. The evergreens had remained crowded and unmoved for years. As a consequence, though tall, they had few roots, and these not of a fibrous character; moreover, they were dried by exposure between the time of taking up and planting. Such examples are bound to fail. They are supposed to produce an "effect at once," and they do, but it is not very good to begin with, and is in a few weeks or months decidedly bad, for they die. Yews and Hollies with an abundance of bushy fibrous roots through periodical transplanting in well managed nurseries—shrubs the very opposite in character of those above described—will grow well if properly planted in moist well worked soil, either in the autumn or the spring, though they may require to be watered and syringed afterwards if very dry weather should prevail. Large, so-called "cheap," shrubs are usually the most costly in the end. If we desired to plant a number of Yews and Hollies we should order them from a good nursery forthwith, expect the roots to be moist on arrival, and they would be planted at once. If the soil were dry we should take care to make the sites thoroughly moist before planting, also immediately afterwards give a good watering. Midwinter planting, when the ground is very cold, is not so reliable as spring planting when the buds commence swelling. We have planted numbers of the evergreens mentioned at the end of October without a failure, and many of a large size proportionately well rooted, the taking up and planting having been well done, and proper attention accorded afterwards; and we have had equal success in spring, but with more after attention, for not one out of a hundred has died. The mere "time" of planting is only one factor, and not the most important, the condition of the shrubs, soil, and methods being of greater moment in accomplishing the object in view.

Names of Fruits.—*Notice.*—Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*F. M. M.*).—Pear is Chaumontel, the Apple Winter Hawthornden. (*F. E. M., Solihull*).—Beurré Clairgeau. (*G. M. S.*).—B, Lady Sudeley; C, Golden Harvey. (*J. Hawkes*).—1, Beauty of Kent; 2, Minchall Crab; 3, Bess Pool; 4, Court Pendü Plat; 5, Cox's Orange Pippin; 6, Beurré Diel. (*J. E. K.*).—1, Gloucestershire Costard; 2, Cellini; 3, Reinette de Caux; 4, Nonesuch; 5, Yorkshire Greenging. (*D. H.*).—1, Blenheim Pippin; 2, Aromatic Russet; 3, Golden Pearmain; 4, Court of Wick; 5, Autumn Pearmain; 6, Cratægus coccinea. (*E. B.*).—These are probably local varieties, which we cannot identify. (*F. A. J. E.*).—A, Duck's-bill; B, Cox's Orange Pippin; C, Golden Noble; E, King of the Pippins.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*T. A. D. M.*).—1, Cotoneaster Simmondsi; 2, Zenobia speciosa; 3, Andromeda floribunda; 4, Escallonia macrantha; 5, Garrya elliptica; 6, a variety of Ceanothus azureus, possibly Gloire de Versailles, but much faded. (*May*).—1, Begonia, no flower being sent we cannot determine the variety; 2, Satureia montana (Winter Savory); 3, Begonia metallica; 4, Cotoneaster microphylla; 5, Onychium japonicum; 6, Aster, probably Amellus bessarabicus. (*Taylor*).—1, Platycerium alcorni; 4, Tradescantia; cannot determine species. The remainder of your specimens were completely dead. If you send again pack in damp moss to keep them fresh. (*W. B.*).—Maxillaria picta.

FRUIT AND VEGETABLE FARMING.

THOUGH there is much to learn about fruit and vegetable growing for market, the knowledge of this generally is far in advance of what is known about the preserving or possible extended use of such produce. What are we to do with it? is the farmer's query when told to grow it instead of so much corn. In support of his question he can point to a frequent glut of markets, of crops upon which no profit was realised, of fruit and vegetables unsold and spoiled. He has some reason then to hesitate till he can see his way with at any rate a greater degree of certainty. Conjointly with improved culture we want to clear the way for a ready market, and to incite an increasing demand for cheap fruit and vegetables of all kinds. Some day Asparagus will be as cheap as other vegetables; its culture will also cease to be confined to special districts. If tillers of the land only knew how they would soon have hundreds of acres under this crop alone, but its mere price on market keeps them back. "Surely such an expensive vegetable must be very difficult to grow," say they, without taking the trouble to look into the matter and seeing for themselves what is possible. If one man had the courage to do so he would soon have a crowd of others following his lead; it is always so. Farmers are about as timid as they are ignorant; not till Scotch farmers led the way in dairy farming in Essex was it taken up by others. Before their arrival corn growing was declared to be the only crop suitable for that locality, climate and soil were alike unsuitable for grazing; yet we now find most of the land under green crops, with very large herds of dairy cows upon it. Just the same thing is said of Suffolk by the East Anglian farmers. Corn is and must be the staple crop for them, say they, and with stolid persistence they continue growing corn. Who will go and teach them to do otherwise? With a surplus of some twenty million quarters of Wheat over the world's requirements its price must continue low even if it falls no farther, and yet we might point to the possibility of Wheat at 20s. per quarter.

Well said Mr. Whitehead in his article in the Journal of the Royal Agricultural Society, to which we referred last week, that

the demand for fruits—preserved and green—can be almost indefinitely increased. It is precisely in this that there are such vast possibilities. A growing popular demand while pointing to a low price also indicates vast quantities. With the growth of a knowledge of the laws of health the true value of fruit and vegetables as really nourishing food will be grasped, and both—but especially fruit—will be required in such quantities and of such excellence that fruiterers' shops will be as numerous as butchers'. They are so practically now; grocers already give much prominence to imported preserved fruits as well as to American Apples in barrels. Of home produce there are jams and bottled fruits, both excellent, but the jam has to be purchased with caution, much adulterated stuff having been pushed into the market even by firms of high standing who ought to see that only a pure article passes through their hands. It is possible that they, as well as consumers, are ignorant of what is really pure, yet the difference is plain enough if pure and impure jam is tasted.

Fruit-canning after the American fashion is not among our home industries yet. Like fruit evaporation it is coming; meanwhile we pay others for doing it, and go on grumbling about hard times and asking for State aid and rent reductions. According to Mr. Shelter, "The process of canning is a simple one, being merely to drive out the germs of fermentation by heating the fruit and excluding the air. Success depends not on the amount of sugar used, but on the entire exclusion of air. To accomplish this there are two methods in use. The first and most perfect method—that employed by the canning factories—is to pack the fruit, neatly prepared, as closely as possible into the glass jars. Fill the jars with a syrup made by boiling water and sugar together in the proportion of about one cup of sugar to one quart of water. This will make syrup enough for two quart jars. Place the jar in a tank or boiler of tepid water on a rack, so as to allow the water to come within an inch of the top of the jar, screw on the cover loosely without the rubber, cover the tank or boiler, and boil till the fruit is done. Ten, or at most twelve, minutes are enough for berries, Currants, or Pears and Apples. Have some syrup ready for filling up the jars. When done remove the jar from the water, fill to the top with hot syrup, wipe off the neck, put on the rubber, and screw down the cover tightly."

The second method is one most used by the housewife in America. It is simply to boil the fruit in sugared water in a porcelain lined stewpan or kettle until it is sufficiently cooked, and pour it boiling hot into the jars, stirring it about with a spoon to let the air bubbles escape; fill up with hot juice or syrup, wipe the neck with a moist towel, put on the rubber, screw down the cover tightly, and tighten again when cold.

WORK ON THE HOME FARM.

The nights grow cold, heavy rains fall frequently; leaves, too, fall fast, and shelter for cows and store cattle is now indispensable. See, therefore, that nothing is wanting to afford them perfect shelter and protection from exposure to high wind and cold showers. One serious fault in many yards is the accumulation of sodden litter to such a depth that cows turned out upon it literally stand in water. Let yard drains be kept open, and remove foul, decaying litter from them sufficiently often to avoid, so far as is possible, any considerable amount of wasting of the manure. Some wasting is unavoidable, and the best plan is to get it away into heaps as soon as it becomes foul and unfit for the cows to stand about on. Many a yard have we seen where the manure is allowed to accumulate from autumn till spring, when it is a seething mass of sodden, decaying vegetable matter 2 or 3 feet thick. The whole thing is a costly blunder, wasteful of manure, and hurtful to the cattle.

Keep all hovels and cowhouses thoroughly clean; use plenty of fresh, clean, dry litter daily, keep feeding troughs and mangers clean too. See that the drinking water is pure, do not use roots to excess, but always in moderate quantities. Keep the best sweet meadow hay for the dairy cows, and as they come altogether off grass give them a Cabbage or two apiece daily. Some Carrots should also now be given to them onwards till the end of the year. Remember that when cows and cattle are kept from exposure to cold and wet the food given them nourishes and sustains condition with a fairly full yield of milk. When they are

exposed the food goes to sustain vital heat, really to keep them alive, and they invariably fall off in condition; some die, others suffer so severely that by spring they are in such low condition as to require months of good grazing to set them up again, which of course means just so much loss to the owner.

Keep small or delicate animals apart from others; an extra division or two in yards is easily contrived, and is quite worth while to keep them from being worried and driven from the food by the stronger ones. To understand the importance of this it is necessary to be frequently among them at all times of the day. It is quite possible to pass a cow-yard daily and yet see nothing of any fighting, yet it invariably occurs if cattle are placed together without careful selection.

NOTICES OF BOOKS.

AGRICULTURAL ENTOMOLOGY.*

IN the preface this edition of her useful work, Miss Ormerod tells how the first edition, published in 1884, appeared likely to remain nearly useless till last year, when attention was drawn to it under the technical education scheme of the County Councils; it then sold off so rapidly as to necessitate the preparation of a second edition. In this new issue its scope has been extended, from being a mere guide to methods of insect life to the means of prevention of insect ravage. Prevention or remedies for the harm done by such pests are given, and the book abounds with useful hints, both for the student and practitioner. To give an example we may take the thick fleshy caterpillars of various kinds, which are so frequently injurious to the Cabbage and Turnip crops, of which we are told that the fact of their usually passing the winter under ground puts them very much in our power. We are also reminded that—

"Before the caterpillar turns to the chrysalis it makes a cell in the earth, in which it is protected from wet and sudden changes of temperature. So long as the caterpillars are thus protected no amount of cold to which they are exposed will, as far as we know, do them the least harm; but if they are thrown out of these shelters to the influence of drying winds or hot sunshine, or to lie soddering helplessly on the surface in moist or muddy ground, or to being frozen in these states, then their constitutions will not bear it. This is one of the great principles of prevention:—Turn out the insect pest from its natural shelter when it is in such a condition that it cannot regain it or make a new one."

In this and in every page of the book bearing upon plant life the importance of thorough cultivation and frequent stirring of the soil is shown. It is in rubbish heaps and untilled soil that the insect finds shelter to increase and multiply. Get rid of the one, break up the other, says the talented authoress, and you will destroy it.

Animal pests are also dealt with, and the fixed laws of insect life fully explained; the book is well illustrated, many new figures being given, and as its full value is realised its circulation will extend. That this will be so is certain, for the technical teacher is constantly being asked for text-books, among which Miss Ormerod's must take a leading place as one of the most useful, and as the best introductory work upon the subject it so clearly expounds.

METEOROLOGICAL OBSERVATIONS.

REMARKS.

- 16th.—Generally overcast, with occasional drizzly showers; a little sun about 10 A.M.
 17th.—Unbroken sunshine till 1 P.M.; cloudy at times after. Heavy showers of conical hail at 2.50 P.M.; rain from 2.30 P.M. to 4 P.M.; generally cloudy after; bright night.
 18th.—Generally fine and sunny, but occasional spots of rain; bright night.
 19th.—Bright and sunny throughout.
 20th.—Fine, with sunshine at times.
 21st.—Overcast early; generally sunny from 10 A.M. to noon. Frequent rain in afternoon.
 22nd.—Bright sunshine throughout; bright night.
 A fine cold week.—G. J. SYMONS.

* *A Text Book of Agricultural Entomology*, by Eleanor A. Ormerod, F.R.Met. Soc., &c. Simpkin, Marshall, & Co., London.

ONE of the difficulties gardeners have to contend with in private establishments is the preparation of the manure for the land they have to cultivate. Very frequently, in fact generally, they have to deal with the litter from the stables and convert it into manure. Unfortunately a superabundance of straw is used, and often a large proportion of the droppings are removed for the growth of Mushrooms. This, then, leaves the cultivator at frequent seasons of the year in possession of a large heap of material that is little better than straw. This litter is often placed in a hole or some convenient position where it remains until it is full; the consequence is it heats perfectly dry, with the result that the nitrogenous matter decomposes, and being a very volatile gas it escapes and is lost. What, however, is not lost has a fair chance of doing so after it passes into the gardener's hands, unless labour is plentiful and time can be devoted to its preparation.

If mixed manures had to be dealt with the matter would be very much simplified; say, for instance, horse and cow manure. The two could be evenly spread. The former, being richer in nitrogenous matter, ferments rapidly and soon becomes heated, while the latter decomposes slowly and gives out very little heat. The one assist wonderfully in the decomposition of the other, and if placed together in nearly equal quantities prevents too rapid fermentation, and consequently loss. We must, however, suppose cow manure is not present, for it very seldom is, and the gardener has frequently to deal with the stable litter being practically confined to its use. He may, by a little scheming or buying, come into possession of some cow manure for various purposes, but that does not affect the question we have to deal with.

The best means when the litter is in the state we have described is to arrange for a good supply of water as close to it as possible, so that it can be well moistened every morning. By this means only can fermentation be kept down and the carbonate of ammonia saved. Better still by far, a tank should be arranged close to the place in which the litter is deposited, so that the drainings from the stables could be pumped over the material. Failing this, however, and very rarely this provision is made, the former must be resorted to and the litter removed as often as possible to the position in which it is prepared for garden use. It is important to have a tank in this yard, so that the drainings of the heap can find its way into it to be frequently returned to the manure during the process of fermentation. Very often the manure yard is minus of this important provision. A hole, however, can soon be made and a tub sunk into it, while the surrounding portion of the hole should be puddled with clay. If this is made large enough the whole of the drainings of the manure may from time to time be returned. It is a decided advantage if the urine of the stables is conveyed to a tank and the litter well moistened with it before the latter passes finally to the manure yard for further preparation. The urine, being the most valuable part of the manure, should not be lost; this, as well as water, will be needed to prevent the heap rising above 80°. Below this temperature fermentation will be slow and safe; instead of carbonic acid being formed and combining with ammonia, decomposition stops and organic acids (ulmic and humic acids) are formed, which form ulmate and humate of ammonia and compounds of potash and soda; these are soluble but not volatile. Great care, however, is needed,

or the temperature will rise too high; in fact, it can only be kept right after it is thrown into a heap by watchfulness and a liberal supply of moisture.

Fermentation may be rapid or the reverse according to the treatment the heap receives. The lighter the manure is thrown together the more freely air enters and promotes rapid fermentation. The more compact the heap is made the slower the fermentation, consequent on a free access of oxygen being largely excluded from the manure. The firmer and moister the heap the less likely is it to become too hot. It must not, however, be too moist or too firm, or else fermentation will not take place. Once the material is sufficiently fermented to place on the land and it is not needed for a time, the heap should be so rounded up at the top that heavy rains will not wash away the essence of the manure. Very often, I am afraid, nearly one-half of the valuable part of the manure is carried away by heavy rains, the nitrates being soluble in decayed material. If a good tank is provided, and the heap protected from as much rain as possible, and the contents of the tank poured over the manure before it is wheeled on to the land, a great loss will not take place. It is wise when the liquid has been returned to the heap to spread it at once, so that the essence of the manure may be evenly distributed on the land.

In large gardens, where there are quantities of short grass from the mowings of lawns and refuse from vegetable quarters, the decomposition of the litter from the stable is more easily effected. Even Cabbage stems, and the straw of Peas and Beans, may be thrown into the heap to decay. The last is rather inconvenient, but not to be despised, especially where the land is heavy, and besides the straw is rich in phosphoric acid. This vegetable refuse soon decomposes, if carefully mixed through the litter as the building of the heap proceeds. It is not always convenient to dig vegetable refuse of this nature into the land, but there is not so much actual waste in the growth of many crops when the refuse matter is carefully mixed with the manure and returned to the land. The stems of Cabbage, Cauliflowers, and other vegetables of a like nature are best thrown out when all the vegetable matter has been decomposed. There is then very little left but woody fibre, and we do not care to return that to the soil. They are generally burnt after leaving the manure heap with prunings of various kinds.

Where a quantity of manure is needed that is rich in nitrate of potash wood ashes should be freely mixed with such a manure heap as we have described. The wood ashes supply carbonate of potash, which unites with the nitrogenous matter of the manure, and thus forms nitrate of potash. The same result is effected when kainit salts are broken and mixed with manure, say a layer of one and then the other. These salts contain "potassic and magnesian sulphates, calcic sulphate and magnesian chloride." Through the decomposition of the manure the sulphate of potash is converted into nitrate of potash.

Gypsum (sulphate of lime) mixed with farmyard manure is perhaps more effective than when used alone. But this is not all, for it possesses the power of fixing ammonia; what might pass off in a volatile form as carbonate of ammonia would be converted into sulphate of ammonia. Gypsum has not only the power of fixing ammonia, but of absorbing it from the atmosphere. It might advantageously be used for spreading on stable floors.

When manure has been thoroughly decomposed it is then that protection from rain is the most needed. In this state plant food is in its most soluble form, and a good deal of it is carried away by heavy rains. It is a good plan to throw the manure into a ridge-shaped heap, and make the surface moderately smooth, so that the water will pass away readily. If time can be found, and the manure cannot be used for some time, we prefer to mix it with a quantity of fresh litter from the stable. This strawy material absorbs the soluble matter, and while it is protected from loss it also aids in the decomposition of the litter which gives so much trouble. The heap should be soiled over to protect it from rain.

For heavy land strawy material is valuable, as it opens up and renders porous the soil, so that air, water, and warmth can enter freely.

The quantity of farmyard manure varies widely according to the nature of the animals and the food supplied to them. If we take a ton of good stable manure it is only estimated to contain from "9 to 15 lbs. of nitrogen, the same of potash, and 4 to 9 lbs. of phosphoric acid," that is 22 to 48 lbs. of plant food. Valuable crops can be obtained by the application of refuse of this nature, but it is by using natural and chemical manures in conjunction that the best results follow. We advise a liberal dressing of stable manure in the usual way, and 3 cwt. per acre of nitrate of soda and superphosphate, using two of the latter to one of the former. These may be mixed and applied just as the crop commences growth, being sown on the surface during showery weather. The nitrate of soda may be reserved until the crop is in full growth, while the superphosphate may be sown on the surface just before the crop is planted. It is advisable to hold back the nitrate of soda because it is so soluble that some of it might be washed through the soil and lost unless the crop is in a growing condition and could take it up at once.

The superphosphate can be obtained ready prepared, and may consist of such minerals as coprolites or slag, the refuse of iron furnaces, treated with sulphuric acid; a good deal of superphosphate is made from these materials. We prefer superphosphate made from bones after they have been ground to a powder. A ton of this should be treated with 50 gallons of sulphuric acid and 100 gallons of water. The bones should be moistened by half the water, the other half being used to dilute the sulphuric acid. The whole should be well mixed, and in a short time the material will be dry enough for sowing. When a smaller quantity is needed it can be made by using the materials advised in the right proportion.—WM. BARDNEY.

HARDY PERENNIAL HERBACEOUS PLANTS.

HARDY perennial herbaceous plants are not so much grown now as they were some forty years ago. At that time no garden was considered complete without a good collection, and there were few places which had not herbaceous grounds or borders entirely devoted to them. But fashion in gardening, as in most things, changes, and since then perennial herbaceous plants have been discarded in a general way to make room for the more gaudy half-hardy bedding plants which have to be propagated annually, and protected under glass for more than six months of the year, entailing a great amount of labour and expense for a brief display of colour for a few weeks during July, August, and September.

Mr. F. L. Olmsted, the distinguished American landscape gardener, writing in one of the gardening papers last month on "English Gardens," says, "Since my last visit to England there has been a decided abatement of the bedding out nuisance, and of all the garish and childish fashions that came in with it. The gardeners and others with whom I have talked have been generally conceding—some with evident regret—that it was going out of fashion. Any who think with it their occupation will be gone had better come quickly to America, where all the beauty that I have been aiming to provide on various grounds is wholly put out of countenance by it. There has never been a square yard of bedding out on any ground under my direction."

I am quite in sympathy with what Mr. F. L. Olmsted has written on the subject. That there has been too much bedding-out in the gardens of this country no one will deny; and, to say the least of it, carpet bedding, to my mind, is childish, garish in the extreme, and I have never failed, when an opportunity occurred, to express my disapproval of it verbally and in writing. I would not, however, advocate doing away with the bedding-out system altogether. A little of it in its place is very good, but there has been too much of it in the past in most places, to the detriment of hardy perennial plants, which, I am glad to say, are coming more to the front now. There seems to be some misunderstanding amongst gardeners and others as to the definition of herbaceous plants. We have seen Roses, Hydrangeas, shrubby Spiræas, and other ligneous plants shown in competition at flower shows as herbaceous plants, and passed as such by judges who should have known better. Now, if I understand properly, herbaceous plants are those that have no woody fibre, and whose stems perish annually after flowering. The plants may be annual, biennial, or perennial; the foliage deciduous or evergreen; and the roots fibrous, tuberous, or bulbous, according to the natural order to which they belong. Anyone with even a slight knowledge of botany should be able to distinguish the difference between plants with woody fibre and those composed of herbage.

Perennial herbaceous plants are easily propagated and cultivated. They may be increased by seeds, cuttings, and division of the

roots, and grown in ordinary garden mould (with the exception of some Alpine and bog plants, that require peat soil) in borders by themselves, or in front of shrubberies and in beds on the lawn. Some of the large growing genera and species, with bold elegant foliage, have a noble appearance when planted in clumps in conspicuous places. *Anemone japonica*, and many other kinds with strong creeping roots, should be planted in beds by themselves, as they soon spread and interfere with the growth of their neighbours. The plants should be lifted occasionally, divided, trimmed, and replanted. When doing this the ground must be deeply dug and well manured. Tall growing varieties ought to be properly staked and tied in good time to prevent them from being injured by storms. Some gardeners recommend cutting the tops off the plants (of some varieties) after they have grown a foot or more, in order to make them dwarf, and later in flowering. I have never practised this method, but I believe it does very well.

I have been in places where they went in more for a large collection than a selection of the best flowering varieties. When this is the case, and the plants are properly labelled, and planted in groups according to their class and order, it reminds one of a public garden for teaching students, and, as a matter of fact, a great many of the plants, which are interesting from a botanical point of view, have no decorative effect in themselves, and their flowers, when cut, are of little service for the embellishment of rooms. Whereas if a good selection were made, and properly attended to, plants with red, white, yellow, blue, purple, and other colours, may be had in flower for at least ten months in the year. I do not wish to make a catalogue, but perhaps I should by way of a finish, name a few of the most important genera and species, and their time of flowering.

Beginning with the year, there are few plants in bloom during January, but the following flower in February and March:—*Hepatica triloba* and its varieties, *Arabis rosea*, *A. alba* and many others, *Helleborus lividus* and *H. niger*, *Tussilago fragrans* (a plant growing wild in great abundance at Llandouch Church, and on the embankment of the Rhimney Railway at Cardiff), *Potentilla alba* and other varieties, *Sanguinaria canadensis*, *Viola odorata*, *Anemone ranunculoides*, *A. apennina*, *Adonis vernalis*, *Primula Auricula*, and others.

April.—Several species of *Phloxes*, *Aquilegia canadensis*, *Dodecatheon Meadia*, *Arabis alpina*, and others. Several *Saxifrages*, *Thalictrum anemonoides*, *Alyssum saxatile*, *Doronicum austriacum*, and others, *Anemone pratensis* and *pulsatilla*, several of the *Iris* family, *Polemonium reptans*, *Pulmonaria virginica*, and other species. These are a few of the many beautiful plants that flower during this month, not to mention the native plants, some of which are charming, such as *Chrysosplenium alternifolium*, and many others I could name.

May.—*Anemone hortensis* and other varieties, *Aquilegias*, several *Dianthus*, *Geums*, *Phloxes*, *Geraniums*, *Veronicas*, *Armerias*, *Pæonia tenuifolia*, and several other varieties, *Polygonums*, *Symphytums*, *Centranthus angustifolius*, *medius*, and *ruber*, *Hesperis matronalis* and its varieties, *Astragalus*, several varieties, *Dictamnus rubra* and *fraxinella*, *Phyteuma spicatum*, *Lupinus*, several *Thalictrums*, many *Monarda fistulosa*, and hundreds of other genera and species of different colours, too tedious to name in a paper like this.

July, August, and September are rich in herbaceous plants, but it would be too monotonous to give even a small list of them here. I think I have said enough to show that there is no lack of useful hardy herbaceous plants to keep our grounds and borders gay during the greater part of the year. To me they are more interesting, and more useful for cutting flowers from than many of the plants that are bedded out, and they do not entail the labour and expense in potting and protecting them during the winter and spring months that the bedding out plants do.—A. PETTIGREW.—(Read at a meeting of the Cardiff Gardeners' Improvement Association.)

FUNCTIONS (AND WEIGHT) OF VINE LEAVES.

VINE culture has ever been a warm subject for discussion, and has lost none of its charms, especially to young men. Many like those here will be showing their practical interest in this discussion by no sooner having read the articles than they are out, lamp in hand, picking leaves for comparison with the weights and measures given in the *Journal*. From a handful of *Hamburgh* leaves five were picked weighing 3½ ozs., and measuring from 12 to 14½ inches across. These are from rods nineteen years old that have carried on an average 30 lbs. of fruit. We began cutting in the middle of August, so that the leaves are fast maturing for parting company with the wood, changing from the deep green to the brown and yellow which reminds of the passing season with bright prospects for the future.

Leaves bring to mind a visit I had from some gardeners recently. When going through the vineries they asked if they were Cabbage or Rhubarb leaves we grew, and if we tied the bunches on to the bottom of the rods. I confess I felt a little flattered. My conceit, however, was soon taken out when comparison was made with my neighbour's, Mr. Osman, then gardener at Wroxhall Abbey; while ours measured 15 inches and over, his surpassed them in every way; and for bunches, well, fit companions for Mr. Dunkin's 6lb. one.

I am glad to learn Mr. Iggulden is to have no part in hurting other men's feelings with this discussion, and all will be at one with him in being sorry that any should have been annoyed before he gave the assurance that he will "stick to his own experience." This is as it ought to be in a discussion of this sort, and not many have had such varied practical experience as Mr. Iggulden, and fewer still can impart it with such interesting and instructive effect. Anyone reading Mr. Iggulden's article at page 345, and scanning between the lines, must conclude he has little faith in his opponents' statements or belief in his authority and information, granting Mr. Dunkin a roving commission, at the same time accusing him of "drawing wrong conclusions—beating about the bush—not competent to give an opinion until he has put into practice what he preaches." This is nothing less than charging Mr. Dunkin with plagiarism in its worst form—viz., taking credit for the product of other men's brains. Castle Gardens are not in a corner, and Mr. Dunkin will expect Mr. Iggulden to call next month when he is passing and see his Vines, "so vastly improved during the last few seasons."—WARWICK.

I AM not surprised to see that "J. J. C." is anxious to know something more about the Vines in the gardens here, which are now carrying such heavy crops of well-coloured Grapes. The weight of crop given on page 346 is now hanging on single rods. True, these rods are somewhat longer than is usually the case, being 25 feet. Still, there is no gainsaying the fact that the crop is enormous. I must also point out that the varieties bearing this weight are Gros Colman, Black Alicante, and Gros Guillaume, which are growing in the same range as the Black Hamburgs, from which the leaves sent to Fleet Street were cut. Every rod of this variety have also carried a heavy crop this year, but as the greater part of the bunches were cut when I gathered the leaves, there was no means of judging, with anything like accuracy, the weight of crop they carried. No fear need be entertained about the Vines "not lasting" under the treatment they are receiving, so long as they continue to produce leaves and wood such as they now possess. The whole question of their treatment I will deal with in due time. I only refrain from doing so now in order to prevent the principal points in the discussion on "The Functions (and Weight) of Vine Leaves" from being obscured by side issues. In the meantime I am pleased to have the support of both "J. J. C." and Mr. G. Garner, who believe in the benefits to be derived from a moderate extension of lateral growth. The latter, I know—from the high quality of the produce he stages at southern shows—to be an excellent grower; the former I can only identify in connection with his views on "Setting Peaches," which appeared in the *Journal* some time ago, and whose recent experience in that matter might at some future time prove interesting.—H. DUNKIN.

MARGARET CARNATIONS AND PINKS.

YOUR correspondent, Mr. S. Arnott, in the *Journal of Horticulture* (page 351) of the 20th ult., has conferred a favour by the information he has given as to their introduction from Italy and in reference to the various sorts, and for the future I shall adopt Mr. Arnott's suggestion, and call them "Margaret varieties."

A letter from Dr. Hogg gives further information as to this new race of the *Dianthus* family, and writes me that "These Marguerite Pinks (they are not Carnations) are very pretty, and appear to me to be a cross with the Indian Pink, D. Heddwigi, and garden Pink, but they are in no sense a Carnation." I notice also that in Mr. Robert Sydenham's seed list for this year, under the heading of Carnation Margarita, says, "This is a very lovely new strain, but should more properly be called Margarita Pinks;" and on looking over a bed of them since I feel that Dr. Hogg is correct in his opinion. But in the Sparkhill hybrids from these Margarets, and a fine exhibition bizarre Carnation, we have the Carnation in habit, foliage, growth, and flowers, losing the Margaret character excepting in freedom of blooming and their being got into strong flowering plants from seed in eight months. I have again seen the Sparkhill plants a few days ago still in good bloom, with more buds to open, symmetrical in growth, in 5-inch pots, and flowers as large and well formed as a good Carnation, but still retaining the serrated edge of the Margarets; but in the hands of

our florists this defect in the eyes of an old florist will soon be lost. This new type is a "coming" flower, with a great future before it.—W. DEAN.

[It would appear from the foregoing that we shall soon have what may be termed (as distinguishing them from florists' varieties) both Margaret Carnations and Margaret Pinks that may be raised from seed and flowered the same season in a similar manner to Indian Pinks; and for decorative purposes we are not so emphatic as Mr. Dean is that the serrated edge is a defect. Our correspondent is a true florist and looks forward for a "florists'" type of the Margaret Carnations, and it is not improbable that his hope will be realised. The point we have in view is this—namely, that the plants we have grown this year, and seen grown by others, from seed sold as Marguerite Carnations are not Carnations, but Pinks both in habit, foliage, flowers, and perfume, and the term Carnation as applied to them is a misnomer. We shall hope to grow the Sparkhill hybrids in due time, which, according to Mr. Dean, are English Margaret Carnations.]

CIMICIFUGA SPICATA.

THIS plant (fig. 53) is similar to *C. racemosa* in general form, the flower stems being several feet in height, and bearing the small white

FIG. 53.—CIMICIFUGA SPICATA.

flowers closely packed on lateral and terminal branches. Being late in flowering, these Cimicifugas form conspicuous objects in the borders during August and early in September, and might advantageously receive the attention of hardy flower lovers. Ordinary garden soils suit them very well, and where large clumps have been formed the plants are really valuable additions to the list of effective hardy plants.

EDUCATION IN GARDENING.

(SILVER MEDAL ESSAY, continued from page 372.)

BOOKS TO CONSULT.

THERE is at all times an element of difficulty in making a selection of books generally applicable to all cases. It would be to the mutual advantage of both gardeners and employers if the latter

could see their way to provide a suitable and general library as part of their garden establishment, as some do. If space allowed much might be advanced in favour of this proposition. Many "Gardeners' Improvement Societies" possess a good selection of works of reference which are of great service in tiding the gardener over such times until he possesses money or opportunity to purchase them. The advantage of absolute ownership are incalculable, and it behoves every young gardener to make strenuous efforts to secure a small library of his own, so selected that points of culture, questions of nomenclature, classification, habitat, and general educational work could be referred to, and points cleared up at any or all times by having the necessary authorities at hand. The self-denial exercised in procuring them, and the pleasant associations and reminiscences connected with consulting them as everyday assistants to knowledge, bring the student in the course of time to look upon them as his best friends and most cherished possessions.

In the following selection many valuable educational works, on account of their cost, are not specially included. Of course, to the specialist they are a matter of primary importance, and it would be his bounden duty to make every effort to secure them. As examples we may mention the "Orchid Monographs," by Veitch; the best works on landscape gardening by authorities like Loudon, Kemp, Major, and Milner, and the advanced books on botany by Sachs, Strasburger, Goebel, Vines, &c. Individual taste, inclination, necessity, and money at command will guide the student in these matters. The selection given fairly covers the practice and theory of gardening, and is based on such lines of economy as is consistent with the wide range of subjects necessary for the gardener to have some knowledge of, if he desires to be stamped with the "hall mark" of proficiency in his calling. The gardeners' rate of wages and education, as a matter of necessity, must partake of a progressive character, so his books must be procured as opportunities permit, of course in their proper sequence. Some of the valuable high-priced works can be had in a serial form, but when purchased in a complete form the buyer should insist upon the usual discount off cash payment. The second-hand bookseller's catalogue will often repay perusal, but in this age of rapid advancement care should be taken that all books purchased of a scientific and standard character are up to date, by obtaining the latest revised editions, or those last published by the best authorities on the subject they treat upon.

LIST OF BOOKS.

Class Books.—"Physiography," J. Thornton, M.A.; "Chemistry," Roscoe; "Botany," Hcnfrey's, 4th edition, revised by Masters and Bennett.

Practical Works.—"Gardeners' Assistant," R. Thompson, ed. 1881; "Dictionary of Gardening," Nicholson (Kew); "Vines and Vine Culture," Barron (Chiswick); "Fruit Culture under Glass," D. Thompson, 2nd ed.; "Fruit Manual," Hogg; "The Fruit Growers' Guide" (now being issued), Wright; "Hardy Flowers and Alpine Plants," Sutherland; "Rose Garden," Paul; "Orchid Manual," 6th ed., Williams; "Elements of Agricultural Chemistry," Johnson, 14th ed.; "A Treatise on Manures," Griffiths; "Agriculture in Some Relations to Chemistry," Storer; "Stove and Greenhouse Plants," Baines; "Diseases of Garden and Field Crops," W. G. Smith; "Diseases of Plants," Marshall Ward; "Injurious Insects," Ormerod; "Horticultural Buildings," Fawkes; "Hot-water Heating," Fawkes; "Colour," Church.

Beyond this list there are plenty of books on special subjects which under certain circumstances the gardener may find to his advantage to purchase—viz., "Mushroom Culture," Wright; "Fruit Culture for Cottagers" (prize essay), Wright; "Tomato," Iggulden; "Chrysanthemums and their Culture," Molyneux; "Coniferæ," Veitch; "Forestry," Brown; "Narcissus," Burbidge and Baker.

The three standard works on gardening by Thompson, Anderson, and McIntosh are each in their way valuable works, though somewhat different in scope, but as it is improbable the young gardener will be able to buy them all I have placed Thompson's on the list, being lately revised and covering most ground, as suiting the under gardener's purse and requirements. Anderson treats more fully than the latter on stove and greenhouse plants, Orchids, landscape gardening, and ornamental trees. Under certain circumstances it might be worth consideration to secure it later, if opportunity offered.

GENERAL ADVANTAGES.

The course of study and education here laid down, looked at from the standpoint of the present-day gardener, will probably appear to be an unnecessarily formidable one, but, as we have already shown, the educational facilities now at command put an entirely new face on the educational side of the question. What

formerly passed for botanical knowledge, and was either condemned or ignored by writers on the gardeners' education question, is widely different from the present-day physiological botany, and what it involves. Formerly it was the height of ambition of the so-called botanist to collect and dry a collection of plants, and learn by rote the catalogue of uninteresting names. To-day it is the study of cause and effect in Nature's workshop, and the gardener who possesses this kind of knowledge must be all the better for drawing it direct from the "fountain head." In cases of emergency it will lift him superior to rule of thumb, and questionable or illogical practice; in fact, it will enable him to formulate new and sound practice, directing him straight to the end in view, and teach him to avoid the mistakes begotten of ignorance and prejudice. Neither can the advantages accruing be summed up or measured by the direct beneficial results upon the gardener's practical work. "Bacon" says, "A man is but what he knoweth. Shall we not as well discern the riches of Nature's 'warehouse' as the benefit of her shop?"

The gardener of the next generation will be poor indeed if he cannot find these riches; but to do so he must also remember that youth and early manhood will need to be wisely spent. Let him cheerfully accept and act up to his duties, and he will find the time spent to this end will also be his most remunerative investment. Youth is thought to be the time for pleasure, and no doubt much may be advanced in favour of reasonable recreation; but pleasure is a slippery path to follow, and requires a strong mind to avoid carrying it to excess. Before a lad is launched on the career of gardening he should be shown the stern realities of the gardener's life as "a contra" to the flowery side from which youth and the inexperienced are apt to view it. He must understand that he will need to be both constitutionally and educationally fitted for the calling, and be prepared to fight keenly in what will simply be a struggle for existence. The present keen competition amongst gardeners will be intensified in the future, particularly so in the higher branches of the profession, and better choose some other path in life than be stranded or drift into the common hack and drudge wherever he may be employed, or become the puppet instead of gardener in the true sense to the unsympathetic, and it may be penurious employer, whose forte is paying the least possible price for services rendered.

FRUIT AT SAWBRIDGEWORTH.

ORCHARD HOUSE FRUIT.

MANY years have passed since Messrs. Thos. Rivers, J. R. Pearson, G. Abbey, "D., Deal," W. Keane and others waged a brisk pen-battle about orchard-house fruit in the columns of the *Journal of Horticulture*. The places of the two first-named, who valiantly supported the pot culture of fruit trees, have been taken by a younger generation, but the work they commenced has been carried on, and the ancestral home of the pot tree at Sawbridgeworth shelters it still. When in looking over the houses there recently Mr. T. Francis Rivers pointed out to me the original tree of Lord Napier Nectarine, now forty years old, but still healthy and vigorous, together with a host of younger specimens, I was tempted to dip back into the past by turning over the *Journal* pages of 1864 and so realise how the faith of those days has been justified. Those who have visited the Earl's Court exhibitions will have been struck by the splendid examples of Apples, Pears, and Peaches exhibited by the Sawbridgeworth firm, and even with most of the fruit gathered and preparations for potting in full swing in the nursery the trees are a wonderfully impressive sight.

PEACHES AND NECTARINES.

I have referred to the old tree of Lord Napier. Its introduction was brought about by one of those fortunate chances that crop up once in a generation. Mr. Rivers happened to see the last fruit hanging just before it would have been removed, all the rest having gone. He was struck by its distinct appearance, and with an acumen that doubtless tended materially to his ultimate advantage possessed himself of the variety. A day later and the famous Nectarine would probably not be with us as it is now, one of the most valuable, if not the most valuable, of its class. The old tree presents quite a venerable appearance with its great gnarled trunk, but its head is fresh with the brightness of youth. It is doubtless a cherished object to its owner, and certainly it is one of great interest to his visitors. The trees, whether young or old, are a wonderful lesson of good management. The wood is stout and vigorous, the foliage ample and richly coloured, and next year's fruiting growths studded with triple buds. Yet the treatment the trees receive is almost startling to those who are altogether unprepared for the course of procedure pursued. When repotting time comes, and it is now at hand, no gentle shaking suffices to free them from the pots, for top-dressings have been heaped up above the rim and are permeated with such a mass of feeders that these have to be torn away before the plants can be freed. They are literally raked out, for a formidable toothed implement is vigorously employed removing soil and fibrelets before plant and pot can be induced to part company. It might be thought that a dangerous check would be imparted by the wholesale sacrifice of roots, but the

plants grow magnificently and yield noble crops year by year. The explanation is that the root hairs are annual and die with the leaves. When their work is done they may be torn away with the same impunity that the foliage may be brushed off after its maturity has been reached. The thick fibres are preserved, and from them a fresh wig of root hairs is pushed in due course. Many do not recognise the limited character of their functions. Though important they are but temporary. When leaves become diseased or are attacked by insects and eventually die some root hairs perish: the same rule tells us that when in the fulness of time the foliage has imparted its matured and elaborated juices to the stem and falls to the ground the balancing agent below ground finishes its duty.

The fruitfulness of these trees is remarkable. They do not produce a great mass of puny blossoms, but large substantial flowers that set perfect fruit. One tree about 10 feet high has borne sixty, and made robust, vigorous, and healthy growth, now ripe and bristling with bold triple buds. Year after year the trees go back into the same size of pot, the balls being reduced as indicated, and the new compost packed firmly around them. Then new root hairs push, and fresh leaves form, the tree, as it were, stretching an arm above ground and an arm below in search of air and food, the one hidden from the other, but both acting in the closest concert nevertheless. What one gives the other elaborates, and so perfect correlation is maintained. It may give some idea of the magnitude of the scale on which pot fruit trees are grown in Messrs. Rivers' nursery to state that the floor of one great house is occupied with a long mound of soil like a huge Potato "pie;" probably there are 100 tons of it, and all is for the pot trees. Kiln dust and horse droppings are the manurial agents chiefly relied on.

APPLES AND PEARS.

These were more striking in one respect than the Peaches and Nectarines when my visit was paid, inasmuch as many were carrying splendid crops of fruit. A tree of Blenheim Orange in a 15-inch pot bore thirty-two superb fruits, beautifully moulded, clear and delicate in texture. It formed a splendid picture. Trees of the charming looking variety, Bijou, in 8-inch pots had seven and eight of the bright red fruits, which, besides being of such pleasing appearance, possess the further merits of good flavour and keeping qualities. Schoolmaster, a seedling from Northern Spy, and which keeps until May, was bearing a number of beautiful bright red fruits. King of Tompkins County and Bismarck were also laden with magnificent examples, and the same may be said of the Pears Pitmaston Duchess, Doyenné du Comice, and Triomphe de Jodoigne, to mention three only. Pitmaston, in a 10-inch pot, was carrying eight noble fruits, and the tree was a very striking object, while Triomphe de Jodoigne was heavily weighted. The way in which the trees develop superb fruits while still making strong and healthy growth is a revelation. But after all the one is perhaps in some degree a consequence of the other. Trees cleared of their fruit are plunged out of doors and will be housed in spring. They are well furnished with fruit buds. The one Cherry in fruit was Guigne de Winckler, and it exhibited the same characteristics. It was carrying a heavy crop of its bright red fruits, which had been hanging ready for eating a month. They were juicy and refreshing, and a dish would form a welcome change in the dessert at this season of the year. In one corner of a large house a huge tree of Royal George Peach forty years old is growing contentedly without any special border, the ground above the roots being quite hard, and all the food it receives are the washings of liquid manure supplied to the pot plants.

PLUMS.

"There has been no profit in Apples this year," said a great Kentish grower to me the other day. "Rivers' Prolific Plum is the thing that has paid us best." There are many acres of it and other varieties in the Sawbridgeworth nurseries. Some are planted with Apples and Black Currants for fruiting, the combination being a decidedly paying one, and in other quarters are strong, healthy trees awaiting orders. The Early Prolific sells in thousands, and so does Monarch, which is also a market Plum of great excellence. The former has an advantage over other varieties in the fact of the early clearance of the crop, which is off in August, affording the tree abundance of time to ripen its growth, and thus it is a constant bearer. There is another Plum on the way, this time a late one. The last fruit was gathered on October 19th. It is a large purple variety, and will probably prove valuable in further prolonging the Plum season, which, considering the many uses of the fruit, can hardly be made too long. Plums do remarkably well in the clayey loam that prevails in the nursery, and Mr. Rivers takes care that a due modicum of lime is provided, in which he is a great believer for Apples and Pears as well as stone fruits.

A GOOD APPLE AND A GOOD PEAR.

The Apple is Rivers' Codlin, the Pear Conference. That section of the fruit-growing public present at the Drill Hall a month ago will have had an opportunity of becoming acquainted with the new Apple, for it was exhibited and certificated there. Should its cropping qualities prove to be of the right sort its future is assured. The Kentish grower above referred to told me that the best paying Apple this season has been Lord Suffield. When the two meet in the market I think that his lordship will have to take second place. There is a certain resemblance between the fruits, although Mr. Rivers says that his Codlin, which is a seedling from American Mother, has no more than a general kinship to the other, but the Sawbridgeworth variety is embellished with a number of rosy

streaks that add much to its attractiveness, and has a powerful aroma. It is unexceptionable when cooked, and Mr. Barron, I understand, can think of no variety to place before it in flavour. Market growers would do well to look after Rivers' Codlin. The tree is a strong and upright grower, and the fruit of fine texture. Conference has had more time to prove its value. This fine Pear was certificated a few years ago. It is in season at the present time, and is of very good quality. The tree forms a natural pyramid, and even on the Pear stock bears early and continuously. These two form a pair that should be added to every garden.

GRAPES.

The Vines at Sawbridgeworth are in splendid health, and Grapes are undoubtedly finely grown, although the greater part of the crop has been cleared. Gros Maroc and Alicante are still carrying excellent bunches, the latter being beautiful examples of ripeness and colour, coated with a delicate bloom. Two newer varieties are also in fruit. One, named St. Antonio, has oval-shaped berries of a burnished black hue, and has very firm flesh of excellent flavour. Mr. Rivers tells me it will hang until May. This should be well worth trial. The other, also a black, rejoices in the name of Prunellas. It will ripen in the Hamburgh house, and is of admirable quality, but the bunches are somewhat too loose at present, and an attempt will be made to improve it in that respect.

ORANGES AND CRABS.

Not in many places do we meet with so fine a house of Oranges as at Sawbridgeworth. A good-sized structure is full of healthy plants with fruit in various stages of ripening. They present a really beautiful appearance, and as ornamental objects alone are very striking. The fruit will hang six months. The chief varieties grown are Silver, Sustain, Long, Maltese Blood, and St. Michael's. The blossom is full of interest, and few fail to appreciate its spicy fragrance. Where the necessary winter warmth can be provided a few Oranges might well be grown. They are easily managed, and after the flowering stage is reached require no pruning. Two of the most effective plants in the open ground are the Yellow and Purple fruited Crabs. The former is roped with fruit like a Damson, the branches drooping almost to the ground, and it is extremely beautiful. The blossom is very sweet, but the same cannot be said of the fruit. The purple is more upright in growth, and the fruit is agreeable in flavour. In shrubby borders such trees would be very valuable at this period of the year, and where fruit trees are planted for effect these Crabs should be represented amongst them.

THE NURSERY STOCK.

The Sawbridgeworth nurseries are extensive, but additions are still being made to them, and this bespeaks an increasing demand for general nursery stock. Apples, Pears, Plums, Cherries, Gooseberries, Currants, and Raspberries are cultivated on an enormous scale for supplying orders. All the popular varieties are represented, and the quality of the trees and bushes leaves nothing to be desired. They have made strong, robust growth, and it is difficult to imagine their failing to give satisfaction. There is the mark of good culture about everything, both under glass and in the open air, and that is the simple explanation of how a high reputation has been won and spread.—W. P. W.

ROSES AT CHRISTMAS.

WITH suitable attention it is possible to secure a fair display of Roses during the closing month of the year, a time when they are particularly welcome. A little foresight during the summer months, combined with proper treatment and a judicious selection of varieties, will do wonders towards enlivening our greenhouses with handsome Rose blooms. But plants for the purpose mentioned will by this time be well on their way to their period of blooming, and so I pass to the next succession of Roses—namely, the first batch intended to flower at Christmas and during the first month of the year. For this purpose they should have been already pruned and now beginning to push into growth. To get them to break strongly abundance of air should be admitted by day and night. They are not susceptible to injury by frost until they have grown about half an inch. An occasional syringing will soften the dormant eyes and aid them to start vigorously. Little water at the root is required at this stage, and a temperature of 45° is ample, and any attempt to hurry them is likely to be fatal to success. As they increase in strength and vigour the temperature can be gradually increased until a maximum of 65° is reached, and more water given according to requirements. Stimulants should be withheld until the buds are seen to form, after which it will be found beneficial if given in weak doses, to be afterwards increased in strength. As the buds expand air should be admitted more freely. A uniform temperature with careful ventilation are the best checks to mildew, although as a precaution the pipes may be brushed over with flowers of sulphur mixed to the consistency of paint. Roses can be forced successfully if planted in borders, but for very early work they are best grown in

pots. It is obvious that they are more under the control of the grower and can be more readily examined if anything appears to be wrong with the roots. Again, it is sometimes advantageous to change their position in the house, and watering can be carried out with greater ease and certainty.—ENFIELDIAN.

ROSES FOR EARLY FORCING.

THERE are not many varieties of Rose that will give an adequate return for the trouble and care which early forcing involves. Among Hybrid Perpetuals I should say Général Jacqueminot is the most suitable for early work, but these do not lend themselves very readily for this purpose. The Teas and the Hybrid Teas furnish us with the best varieties for early flowering, but the number available is not large, although they include among them some of the best known Roses we have. Of Teas proper the best one for early work, whether planted out or in pots, is Niphetos. The pure colour and floriferousness of this variety make it indispensable where early Roses are required. Anna Ollivier follows on in point of merit. Souvenir d'un Ami, Safrano, and Isabella Sprunt are good when bright yellow Roses are in requisition.

Of the Hybrid Tea class Lady Mary Fitzwilliam ranks among the very best of early Roses, although it is seldom included among those for flowering at Christmas. It requires some management to produce it in a fit condition for the purpose, and it does not break very freely, but the cultivator can rely as a rule upon obtaining two flowers to every pruned shoot and three occasionally, very few coming blind. This variety would probably be popular as an early Rose if it possessed a more vigorous habit of growth. This sort concludes our list of early flowering Roses with the exception of Maréchal Niel, with which I hope to deal in a future issue.—ENFIELDIAN.

NOTES ON SOME OF THE NEWER ROSES.

I CAN offer a few notes on some of the newer Roses which may be useful to those about to purchase, for, though I have been unable to visit any of the Rose nurseries this season, or even to attend the N.R.S. Show at Chester, I have grown several and seen blooms of others.

HYBRID PERPETUALS.

AUGUSTINE GUINOISSEAU (Guinoisseau, 1889) is called a white La France, and certainly seems to be one. Now, in "E. M.'s" analysis (for which I must take the opportunity of thanking him and of generally agreeing with his remarks upon the different varieties), we find La France taking the second place on the list of H.P.'s, and might therefore expect a white La France to be also a fine show Rose; but it does not seem to have that character at present, and I had no blooms with pretensions to show form. Still, La France itself does not do very well with me, and another year we may see its white cousin taking higher rank.

CATHARINE.—The late Rev. H. T. Frere had a light coloured sport from Comtesse d'Oxford, which he thus named, and exhibited a few years ago for the gold medal. They were very poor specimens, shown in wretched condition, but I begged a plant or two in memory of him after his death, and this year succeeded in getting a representative bloom. It is quite good, but not distinct, being neither more nor less than Pride of Waltham.

GUSTAVE PIGANEAU (Pernet et Ducher, 1889) has deservedly attained such popularity as hardly to require further notice as a new Rose. As "E. M." says, its growth as a cut-back is the principal doubt, and I am bound to say that I fear it will be found a poor grower.

JEANNIE DICKSON (Dickson, 1890) is a Rose of first-class quality, and, as far as I have seen at present, I consider it the best of the Irish H.P.'s.

MARCHIONESS OF DUFFERIN (Dickson, 1891) is of grand size and growth, but not, I think, of such fine form as the last named. My blooms were, however, considerably spoiled by rain, and further trial will, I hope, show this variety to better advantage.

MARCHIONESS OF LONDONDERRY (Dickson, not in commerce).—Messrs. Dickson were kind enough to send me a bloom of this very large Rose. I heartily hope it will prove to be all that Mr. Graham and "J. B." anticipate. I was abundantly satisfied as to its size, fulness and fragrance, but not as to other necessary qualities for a good Rose. It is something the colour of Devonensis, ivory white, is not quite so showy as paper white and perhaps more likely to look dingy, but on the other hand possibly better able to stand a little rain.

MARGARET DICKSON (Dickson, 1891).—I had three dozen strong maidens on Briar cuttings of this Rose, and, judging from the examples shown by the raisers, thought I was going to have a real good thing. I do not know when I have been so disappointed; the growth was very strong, and most of the plants flowered, but I had not a single bloom fit to show. As exhibited, Margaret Dickson resembled a fine Merveille de Lyon with its one great weak point—the centre abundantly filled with a symmetrical point. My blooms utterly failed in this particular; they were even more hollow than Merveille de Lyon itself, smaller in size and shorter in petal, though on strong stout healthy stems 4 and 5 feet high. I am unable to account for this, nor can Messrs. Dickson, who have continued to show it in fine form. I hear that there have been some complaints of the plants not blooming, but this is sure to be the case when a Rose much in demand has been propagated from unbloomed shoots. Nearly all my plants bloomed, so the disappointment was the greater. However, one must give a new Rose time; many suffer at first

from over-propagation if much esteemed, and I have not lost my faith in Margaret Dickson.

MRS. ARTHUR WILSON (Swales).—This is a cross between Gabriel Luizet and Mdle. Eugénie Verdier, with the wood of the latter and something of the flower of the former. I had a few good plants, but was unlucky in not getting a representative bloom. I fear it is no advance upon existing varieties.

MRS. PAUL (Paul & Son, 1891).—This Rose quite answered my expectations. A fair proportion of the blooms come with a well defined centre, showing up grandly against the stout, broad, smooth outer petals, and making exhibition flowers of fine form, though rather patchy in colour. But it does not seem to me to be free-flowering or a good autumnal. My second growths have shown no sign of buds, which is odd in a member of the Bourbon race. Perhaps it will improve in this respect.

SALAMANDER (W. Paul, 1891).—I have not seen this year any maiden blooms of this Rose, but have had some little flowers from a purchased plant, and even the smallest has been of good form with a fine pointed centre, and I have good hopes that it will prove valuable. It appears to be of quite fair average growth.

TEAS.

CLEOPATRA and ERNEST METZ have both "won their spurs" handsomely, but the former is a very bad grower with me, even as a standard. It is most difficult to find buds sufficiently good for propagation till quite late in the season, and even then the working them is almost as bad as threading a needle.

ETHEL BROWNLOW (Dickson, 1887), is not now a new Rose, but I mention it because I am surprised to see that it was not shown sufficiently to figure in the Rose Analysis. My plants did very badly up to 1891, when they all suddenly took to growing well, and the habit is now quite different with me to what it was three years ago. The plants suffered from the weather this year in common with other Teas, but appear to be rapidly improving and coming to the fore; the best specimens I have ever seen having been exhibited this season. There can be no doubt that a good specimen is quite first class, and I look upon it as one of the best of the Irish Roses.

WABAN (Wood & Co., 1891).—I have not seen a good specimen of this Rose, but the only bloom I had was quite distinct in colour, being at first of a dark red. If really a sport from Catherine Mermet, I think that high anticipations may be held of it.

ROSES AT THE CRYSTAL PALACE.

Of the new Roses shown at the Crystal Palace, the first place must be given to Mrs. W. J. Grant. One or two of Messrs. Dickson's new Roses have appeared to me to be wanting in the high centre, which especially gives "quality" to a Rose; they have been all Rose and no point. Mrs. W. J. Grant, on the other hand, as shown at the Palace, was all point and no Rose. But it seemed likely that this was merely because the flowers were not sufficiently developed, and that this was so was shown later, I am told, at Chester. It was certainly very promising and very distinct. Corinna was shown again by Mr. W. Paul. I think it will prove good, though perhaps not quite up to the gold medal standard.

Henry Gow and Captain Hayward are both strong growers, and at least one fairly good bloom was shown of each. They were decidedly better, I should say, than a large proportion of the French Roses annually sent out. Would it not be well for the N.R.S. to give certificates to those which reach a certain standard of merit, though not worthy of a gold medal?

Clara Watson, shown by Mr. Prince, looked a good deal like Souvenir de Paul Neyron. It seemed to be of poor growth, which makes a great deal of difference in its value, for a Souvenir de Paul Neyron of vigorous growth would be quite an acquisition.

Spenser and Lady H. Grosvenor, as shown by Mr. W. Paul, seemed to me to be too flat. I fear I have a "fad" for a high-pointed centre as giving quality to a Rose.

I have heard a capital account of the Duke and Duchess of Fife, upon which Messrs. Cocker should be congratulated. The former, a crimson scarlet Etienne Levet, must surely be a great acquisition.

Madame Caroline Testout, H.T., and Elise Fugier, T., were shown by Mr. G. Paul at the Palace, and both are highly spoken of. The latter, which has received a good deal of commendation, appeared to be better shaped than Niphetos and more inclined to the form of Innocente Pirola.

I hope someone will be able to supplement or correct these imperfect notes, or give some information upon new Roses which I have not seen.—W. R. RAILLEM.

TEA-SCENTED ROSES FROM CUTTINGS.

THE article of Mr. Dunkin (page 349) on Tea Roses reminds me of plants I now have in 6-inch pots advancing into bloom. The varieties are principally those he enumerates. They are from cuttings taken off forced plants in April. After the shoots had flowered they were taken off with a heel, leaving three pairs of leaves to each cutting. They were inserted three or four around the sides of a 60-sized pot and placed in the propagating case. When rooted the plants were placed singly in the same sized pot, grown in a warm pit, and eventually transferred to the 6-inch pots. The plants are now a good size, arranged near the glass in a structure where the night temperature ranges from 55° to 60°. They are advancing finely into bloom, and I hope to cut

buds from them throughout the winter. After the buds open the shoots must be severely pruned, as the back breaks produce the strongest growths, and consequently the best blooms. It is astonishing the size Tea Roses may be grown in a few months from cuttings struck and grown with warm treatment throughout the summer. Tea Roses are invaluable for buttonholes during the winter months, and considering the ease in which they may be produced they should be had in quantity.—A. Y.

GROWING MOSS FOR ROSE BOXES—INFORMATION WANTED.

HAS anyone succeeded in raising artificially good moss and in sufficient quantity to be of use to the exhibitor? That this is a real want I need only mention. I have to send two miles to procure good green moss. I have done so for years now. My well known, for his amiability, friend "D., Deal," told me I was using "hay" instead of moss. It really was brown as old "hay," but true moss. Can anyone suggest how to grow a good breadth of moss artificially without sacrificing valuable ground? I have no old walls to scrape.—THE DOLEFUL ROSARIAN.

ROYAL HORTICULTURAL SOCIETY.

NOVEMBER 1ST.

THERE was a fair display of bloom at the Drill Hall on the above date. Orchids were well shown for the time of year, and Chrysanthemums were in evidence. Fruit was poorly represented.

FRUIT COMMITTEE.—Present: Phillip Crowley, Esq. (in the chair), Dr. Hogg, H. Balderson, J. Smith, J. Willard, G. H. Sage, A. Dean, W. Warren, G. Bunyard, H. Pearson, Rev. W. Wilks, H. Weir, T. F. Rivers, G. Hammond, and J. Cheal.

Fruit was not very plentiful. Mr. T. H. Crasp, Canford Manor Gardens, Wimborne, staged a number of dishes of Apples for which a bronze Banksian medal was recommended. The best varieties amongst these were Cox's Pomona, Hollandbury, Ribston Pippin, Fearn's Pippin, and Mère de Ménage, the last named being exceedingly well coloured. Mr. W. Iceton, Roehampton, showed two baskets of well-coloured Grapes, and was accorded a cultural commendation. A vote of thanks was accorded Mr. J. Watkins, Pomona Farm, Hereford, for several dishes of Apples. Some bunches of Grapes, including Black Monukka, Mrs. Pearson, Royal Ascot, Cannon Hall Muscat, and a seedling were sent from the R.H.S. Gardens at Chiswick. Messrs. J. Veitch and Sons showed a dish of well grown Marie Louise Pears, and Messrs. T. F. Rivers & Sons a new seedling Plum named *Rivers' Late Orange*. The latter was awarded a first-class certificate. The fruits are medium size, orange yellow colour, very firm, and of excellent flavour; a valuable late variety.

A collection of Turnips, including Model White, Golden Ball (Dobbie), New Marble, Harrison's Exhibition (Harrison), White Flat Dutch, and Large White Globe (Vilmorin), came from the Society's gardens at Chiswick, as also did a large number of Savoy and Cabbages.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair), G. Phippen, G. Paul, J. Fraser, W. Bennett Poë, Chas. Noble, T. Baines, W. Bain, C. Jefferies, H. Cannell, W. Furze, H. Turner, C. E. Pearson, T. W. Girdlestone, and B. Wynne.

Chrysanthemums, as may be expected, were a feature. Messrs. H. Cannell & Sons, Swanley, Kent, sent a dozen blooms of Vivian Morel, decidedly the best we have seen this year. A similar number of Col. W. B. Smith, shown by the same firm, also attracted attention, the flowers being very massive and of a golden bronze colour. Two more boxes of miscellaneous blooms were also shown by Messrs. Cannell, and amongst others a splendid flower of Beauté de Toulousaine was noticeable. This partakes after E. Molyneux, but is richer in colour. A variety named Golden Ball was adjudged an award of merit, and is described below. Messrs. J. R. Pearson & Sons, Chilwell, Notts, sent half a dozen new varieties of Anemone, Japanese and single types. They were Delaware, Mdle. Mathilic Brun (A); Purple Queen and Emily Doone (J); Dawn (an attractive single) and a seedling Jap. Emily Doone secured an award of merit. Mr. H. J. Jones, Rycroft Nursery, Lewisham, showed several new Chrysanthemums, and secured an award of merit, as also did Mr. R. Owen, Maidenhead. These are referred to below.

Messrs. Anthony Waterer, Knaphill, Woking, sent a collection of autumn foliage, comprising several Vacciniums, Acers, Andromeda, and Quercus coccinea splendens, the latter a charming red-leaved Oak. Messrs. J. Veitch & Sons, Chelsea, staged a collection of Nepenthes, including thirty-one of the best varieties, the most attractive among them being the well-known N. Rafflesiana, N. Cheloni, N. Northii, and N. Mastersiana, the latter a very dark hybrid (gold medal). Mr. J. McLeod, Dover House, Roehampton, sent a group of well-grown Bouvardias (silver medal); and Lord Rothschild, Tring Park, a new perpetual yellow flowering Carnation, which was passed. A number of Begonias that had been used for bedding during the present year came from the Royal Gardens, Kew; and Hoya imperialis from Mr. F. W. Moore, Glasnevin Botanic Gardens, Dublin. The latter was awarded a first-class certificate, and is referred to elsewhere. Mr. R. Mackellar, Abney Hall, Cheadle, sent Ixora Duff; and Lady Cave (gardener, Mr. Poole) Cleve Hall, Downend, showed Rhipidophora lancifolia. Messrs. B. S. Williams staged a small collection of Nerines.

For a collection of Chrysanthemum blooms, undressed, Mr. T. Osman, gardener to L. J. Baker, Esq., Ottershaw Park, Chertsey, secured the first prize. The flowers were neat and of good form, the best being

Sunflower, Louis Boehmer, E. Molyneux, Elaine, and Maggie Mitchell. Mr. G. Wythes, gardener to the Duke of Northumberland, was second, the flowers in this case being set up in a tasteful manner. Mr. J. Douglas, Great Gearies, secured the first prize for twelve new Chrysanthemums, amongst which were some good blooms of W. Tricker, W. H. Lincoln, Vivian Morel, and Gloire de Rocher.

ORCHID COMMITTEE.—Present: H. J. Veitch, Esq. (in the chair), Dr. Masters, Messrs. J. O'Brien, C. Pitcher, T. W. Bond, H. Ballantine, H. M. Pollett, W. H. White, T. B. Haywood, J. Jaques, and H. Williams.

If not so extensively shown as is sometimes the case, there were many choice things amongst the Orchids. Messrs. F. Sander & Co., St. Albans, sent a small group, for which a silver Banksian medal was recommended. Amongst these were Cymbidium hybridum Winnianum, and Cattleya labiata var. Sanderæ. These were honoured with certificates, and are referred to below. Messrs. J. Veitch & Sons, Chelsea, also staged several beautiful hybrids, some of which are mentioned elsewhere, these likewise being awarded certificates. Messrs. B. S. Williams & Son, Upper Holloway, sent a large collection, which made a charming display (silver Flora medal). Sir Trevor Lawrence, Burford Lodge, Dorking, sent a spray of Spathoglottis Vieillardii rubra, for which a first-class certificate was awarded. Messrs. Hugh Low & Co., Clapton, staged a small collection, amongst which the beautiful Vanda cærulea was conspicuous.

CERTIFICATES AND AWARDS.

Cymbidium hybridum Winnianum (Sander & Co.).—This is a cross between C. giganteum and C. eburneum, and was raised by Mr. C. Winn, The Uplands, Selby Hill, Birmingham. The plants shown had five spikes of flowers, nine or ten blooms being on each. The sepals and petals are creamy yellow, as also is the lip, the latter being spotted with dark crimson (first-class certificate).

Cattleya labiata var. *Sanderæ* (Sander & Co.).—This is a beautiful variety. The sepals and petals are of a delicate mauve tint, the lip white with a rich velvety purplish magenta shade and yellow throat (award of merit).

Lælia elegans excellens (T. Statter, Esq.).—One spike carrying four flowers of this was shown. The petals are rosy mauve colour, the sepals being lighter and narrower, whilst the lip is of charming magenta crimson shade (award of merit).

Cypripedium Arthurianum pulchellum (Veitch & Sons).—This is a hybrid between C. insigne Chantini and C. Fairrieum. The dorsal sepal is of a pale greenish yellow colour with brown spots, the petals being darker. The lip is also of a striking olive green shade (award of merit).

Cattleya leucoglossa (Veitch & Sons).—This is a charming hybrid, the result of a cross between C. fausta and C. Loddigesi. The sepals and petals are a delicate rose colour, the outside of the lip being of a similar shade with a white fringed edge and yellow blotch in the throat (award of merit).

Lælia Perrini nivea (B. S. Williams & Son).—The petals and sepals of this variety are, as its name implies, pure white, as also is the lip, the tip of the latter being fringed and of a very pale soft pink shade (award of merit).

Spathoglottis Vieillardii rubra (Sir Trevor Lawrence).—A charming variety with purplish magenta flowers, the lip being of a richer shade, and orange yellow throat (first-class certificate).

Hoya imperialis (F. W. Moore, Dublin).—This is a splendid species with large curious flowers of a reddish and cream colour. The flowers are sweetly scented (first-class certificate).

Chrysanthemum Emily Doone (J. R. Pearson & Sons).—A beautiful incurved Jap. The flowers are large and of good substance. The florets are white, changing to pink as they mature, the centre being pale yellow (award of merit).

Chrysanthemum Golden Ball (H. Cannell & Sons).—An attractive reflexed variety of a bright golden yellow colour (award of merit).

Chrysanthemum W. H. Atkinson (H. J. Jones).—A massive reflexed Jap, of a reddish brown colour (award of merit).

Chrysanthemum Vesuvius (R. Owen).—This is an English-raised October-flowering variety. The flowers are medium-sized, and of a deep golden brownish shade (award of merit).

Croton Beatrice Horsfall (Mrs. Horsfall).—An attractive variety. The leaves are narrow, of a dark bronzy green shade, with red centre rib and bright yellow base (award of merit).

Plum Rivers' Late Orange (Rivers).—A valuable late variety. Fruit medium-sized, roundish, and of an orange yellow colour, faintly spotted with crimson; flesh firm, and of excellent flavour (first-class certificate).

LECTURE ON FRUIT TREES IN POTS.

A PAPER on the above subject was read by the Rev. W. Wilks at the afternoon meeting. Dr. Hogg occupied the chair.

The lecturer, who dealt with his subject in a masterly style, laid special stress on the importance of repotting the plants every year, and remarked that a good feeding compost should be used, the roots being entirely cleared of all old soil, which must be replaced with new. Watering, the lecturer said, was one of the most important details in the successful culture. A very rich mulch should be given to the plants in or about April, afterwards using liquid manure freely.

His house, which is 48 feet long by 20 feet wide, and 12 feet high to the ridge, will hold twenty-eight Peaches and Nectarines, twenty-one Pears, and twelve Plums. The latter, Mr. Wilks remarked, are shifted when the trees become the least crowded, and during the six years that the house has been in use he has never failed to get a hand-

some crop. He has no doubt that by continuing the generous treatment he has hitherto accorded them, they will continue to bear as fruitfully for another four or five years, after which, if they do not crop, he will not object to lay in a fresh stock. The most absolute cleanliness, both of the house, the plants, and the pots, is an essential to success.

At the conclusion of the paper some interesting remarks were made by Messrs. Rivers, Cheal, Bunyard, and Cannell, to which Mr. Wilks responded.

Hearty votes of thanks to the Rev. W. Wilks for his most admirable paper, and to the Chairman, concluded the meeting.

EVENTS OF THE WEEK.—Chrysanthemum Shows are now the order of the day, and a list of the leading Exhibitions to be held during the ensuing week is given on another page. Regarding metropolitan horticultural events, however, it may be here mentioned that a three-days Show opens at the Royal Aquarium, Westminster, under the auspices of the National Chrysanthemum Society, on Tuesday, November 8th. Kingston and Surbiton Exhibition will be held on the same day. Several auction sales will take place, for particulars of which see advertisements.

— **THE WEATHER IN LONDON.**—During the past week the weather has been of a variable character. On Sunday it was mild and bright, though rain fell heavily all night, continuing more or less on Monday. Tuesday it was colder, dry, but dull, and inclined to be foggy. A sharp frost occurred at night, and at the time of going to press it is very cold and foggy.

— **THE WEATHER IN THE NORTH.**—Severe frosts prevailed here during the nights of 24th and 25th October, and Dahlias and Tropæolums were destroyed on the night of the 24th ult. The frost on the night of the 25th was very intense, but on Wednesday, the 26th, the wind changed to the S.W. about midday, and rain followed. The 27th, 28th, and 29th were wet. Sunday, 30th, was very fine and mild, the autumn Crocuses opening out beautifully to the rays of the sun. To-day (31st) is very foggy and frosty. The minimum temperature on the grass at Dumfries (nearly ten miles, as the crow flies, due north) was 14° during the night of the 25th. On the 24th it had been 16°.—S. ARNOTT, Dumfries, N.B.

— **ROYAL HORTICULTURAL SOCIETY.**—MEETINGS IN 1893.—The meetings of the Royal Horticultural Society during 1893 will be held as nearly as possible as under:—January 17th; February 14th; March 14th, 28th; April 11th, 25th (Auricula Show); May 9th, Temple Show, 24th and 25th, or 25th and 26th; June 13th, 20th; July 11th Show at Chiswick, 25th Carnation Show; August 8th, 22nd; September 12th, 26th (possibly a great Show at the Agricultural Hall, Islington, early in this month); October 10th, 24th; November 14th, 28th; December 12th.

— **NATIONAL AMATEUR GARDENERS' ASSOCIATION.**—A paper on the "Carnation as a Garden and Exhibition Flower," by Mr. Rowan, was read at the monthly meeting of the above Association, which took place at the Memorial Hall, Farringdon Street, E.C., on Tuesday, November 1st. Mr. Rowan was unable to be present owing to illness, and his essay was read by Mr. Terry. There was a very large attendance of members, and Mr. T. W. Sanders, F.R.H.S., presided.

— **WINTER CHERRIES AND HONESTY.**—For vase decoration in winter when flowers are scarce nothing more beautiful and cheerful could be used than a mixture of *Physalis Alkekengi* and *Lunaria biennis*. The brilliant orange capsules of the Winter Cherry harmonise admirably with the transparent white seed vessels of the Honesty. They light up a room on a dull day in a most welcome manner.

— **PRESTON AND FULWOOD HORTICULTURAL SOCIETY.**—The forty-ninth monthly meeting of members will be held in the Council Chamber of the Town Hall (by permission of His Worship the Mayor) on Saturday evening, November 5th, 1892, when Mr. James Hathaway, gardener to Lord Lathom, will read a paper on the "Tomato and its Cultivation." Prizes will be awarded for Tomatoes, Chrysanthemums, and fruit.

— **POTATOES IN RUTLANDSHIRE.**—Large crops of Potatoes are being lifted in the neighbourhood of Oakham, and there is, on the whole, an exceedingly good yield, with scarcely a diseased tuber.

— **NEW PARK FOR NORTHAMPTON.**—It is said that Lord Wantage has generously offered to the Northampton Town Council the free gift of Abington Abbey and twenty acres of land for a people's park.

— **CORNFLOWERS.**—I note what Mr. S. Arnott says about the annual Cornflowers on page 381. I started these annuals with but two shades of blue, and now I have nearly a dozen distinct colours, with many shades.—W. T.

— **PORTSMOUTH CHRYSANTHEMUM SHOW.**—We are informed by telegram that the following awards were made yesterday (Wednesday) at Portsmouth:—In the class for forty-eight blooms—first, Mr. N. Molyneux; second, Mr. Neville; third, Mr. Inglefield. Twenty-four.—First, Mr. Inglefield; second, Mr. Molyneux; third, Mr. Penford, Twelve Japanese—First, Mr. Agate; second, Mr. Hawkins. Twelve incurved.—First, Mr. Hawkins; second, Mr. Steptoe. Group.—First, Mr. Hatch; second, Mr. Hunt. Twelve specimen plants.—First, Mr. Burridge. Six plants.—First, Mr. Lambert. Six blooms of any one Japanese.—First, Mr. Molyneux, with Avalanche. Six any incurved.—First, Sir Wm. Pink, with Princess of Wales.

— **A FRIENDSHIP GARDEN.**—It is reported that at Easton Lodge a flower garden has been laid out under the personal direction of Lady Brooke, who terms it her "Friendship Garden," her friends and relatives being invited to plant trees, evergreens, &c., there as mementoes of their visits to the Lodge. During a recent visit the Prince of Wales planted a specimen of *Salisburia adiantifolia* in this romantic spot. Lady Brooke is also arranging a Shakespearean border, the object being to include in it every plant mentioned in Shakespeare's works.

— **WHY DO PLANTS GROW?**—In discussing this question before the members of the North of Scotland Horticultural Association recently Mr. Mortimer of Tullos indicated the composition of the substances that were required for the growth and nourishment of plants—air, water, and earth; and said that one must properly understand these before they could thoroughly cultivate plants. These removed from the soil the materials for their own subsistence, and plants that required the same materials ought not, he said, to be grown two years in succession, because they would prove injurious to each other.

— **POTATOES IN AUSTRALIA.**—Various experiments which are being made in France with a view to the improvement of the Potato have attracted a good deal of attention in Australia. According to a statement recorded in the *Agricultural Gazette of New South Wales*, no fewer than 110 growers have obtained from a variety known as Richter's Imperator from 12 to 20 tons per acre, while the average is over 14 tons to the acre. The Minister of Agriculture in New South Wales has approved of 1 cwt. each of this and any other three sorts highly reputed in France being imported for experimental purposes.

— **WINCHESTER AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.**—At the fortnightly meeting on the 27th ult., Mr. E. Molyneux, The Gardens, Swanmore Park, read a paper on the Apple to an appreciative audience, illustrating his remarks with branches of trees to show the results of different systems of pruning. There was a representative exhibit of Apples contributed by various members of the Association, the largest collection coming from Mr. G. Mildon, gardener to Miss Turnour, Kingsworthy House, who staged thirty dishes of remarkably fine, well-coloured fruit. On the 17th inst. a lecture on manures will be delivered by Mr. Alexander Dean, F.R.H.S.

— **STOPPING CUCUMBERS AND MELONS.**—Mr. Dunkin is a little hard on Mr. Swan anent the latter's remarks on stopping Cucumbers. For summer crops I always stop the laterals at every joint after the plants are fairly started and the framework laid. It was a practice I adopted from an old and very successful grower well known to the Editor of the *Journal*. Melons I stop at two leaves beyond the fruit and no other laterals are allowed to form; the trellis, however, being covered with well developed leaves from the non-fruit-bearing laterals. As regards depth of flesh and full flavour, the fruits would compare favourably with any Mr. Dunkin could produce on the extension system he champions. I go in for the happy medium in stopping laterals of both Vines and Melons, the manipulation of the growth being very similar.—A. YOUNG. [The crops of Cucumbers produced by the "Old Grower" referred to over a series of years we have never seen excelled.]

— **ANEMONE JAPONICA ELEGANS.**—How seldom do we see this *Anemone* mentioned in the horticultural Press, notwithstanding its effectiveness on the herbaceous borders or when grown in a mass in the shrubbery. For cutting, too, the blush pink flowers are useful, but as a border plant it is most valued. If anything it is of a rather stronger growth than *A. japonica alba*.—E. M.

— **RAINFALL AT CUCKFIELD.**—The total rainfall at Cuckfield, Sussex, for October, was 5.24 inches, being 1.29 inch above the average. The heaviest fall was 0.93 inch on the 30th; rain fell on twenty days. The highest temperature was 58° on the 29th, lowest 30° on 24th. Mean maximum 51°, mean minimum 40°, mean temperature 45.1°. Partial shade readings 1° above the average.—R. I.

— **BOUVARDIA PURITY.**—What a chaste and strongly scented *Bouvardia* this is! It appears to resemble *Humboldtia corymbiflora*, only more dwarf and free flowering than that kind. After seeing the note by "H. W." on *Bouvardias* at Messrs. Veitch's nursery the above variety suggested itself to me, as I notice it does not appear in his list.—A. Y.

— **STEVENSONIA GRANDIFLORA.**—It is a pity this Palm will not conform to ordinary treatment. To grow it well it requires a high and moist temperature and to be shaded from strong sun. I see the flowering of this rare Palm is noted as an event at Kew. Mr. George Legg, when at Cleveland House, Clapham, used to occasionally exhibit a splendid plant. It is too tender for decorative purposes.—A. Y.

— **GRAPES AT WATERLOW PARK.**—The thousands of people who now daily visit the Chrysanthemum Show at Waterlow Park, Highgate, are much interested in the Grapes that are hanging in the vineries. The bunches are of medium size and well coloured, considering the fact that previous to last year the Vines were sadly neglected. As mentioned in these pages some weeks ago, all the Grapes and other fruit grown at Waterlow Park are distributed amongst the various metropolitan hospitals.—C.

— **THE WEATHER IN THE BINGLEY DISTRICT (YORKSHIRE).**—The first snow of this season fell here on the morning of the 24th ult. The two following mornings we registered 11° frost, and on Thursday rain fell during the greater part of the day. Friday and Saturday were remarkable for being extremely mild, the thermometer standing as high as 53° at half-past six in the morning. Apples in these gardens have been a failure with three exceptions—namely, Duchess of Oldenburg, Emperor Alexander, and Betty Geeson, the second named being the heaviest bearer.—T. H. B., *Milner Field*.

— **SCHOOL GARDENS.**—One of those active and energetic persons who constitute in so high a degree the force which impels to good work, a local technical education secretary, remarked the other day how very much he would like to obtain in a suitable situation in each village under his jurisdiction a small area of ground, perhaps one-eighth or one-fourth of an acre, which could be utilised as real training grounds for the oldest and most energetic lads in the village schools, as horticultural practice gardens. It wears a most hopeful look when we see a movement of this description fostered and assisted by the county councils, and aided and supervised outside the ordinary elementary school management and teaching staff. One weak feature of all the proposals made hitherto in the direction of instructing children in gardening, was the almost entire absence of knowledge, either practical or theoretical, on the part of school teachers. In a limited degree that difficulty is being overcome by inducing school teachers to attend horticultural classes, and thus become fairly proficient in at least theoretical horticulture. But to make apt pupils or teachers practical knowledge is needful, and school gardens for advanced boys seem to present in an eminent degree the means to the desired end. We have in a very few places school gardens already in existence, and in all our large industrial or pauper schools where there is garden ground, the boys have in these some practical horticultural instruction. Still we want to see this sort of thing universal, as in that way we may hope to see quite a new stimulus given to gardening and a deep interest aroused in all that concerns both the culture of the soil, and hardy fruits and vegetables. I am glad to know that a commencement has been made in the direction indicated in Surrey. Groups of continuation school gardens have been formed, and some of them cropped during the present season, and steps are being taken to extend the system. An experimental garden on a larger scale is, I hear, to be established in Derbyshire.—A. D.

— **THE WEATHER IN PERTSHIRE.**—The intense frost of the 25th and 26th ult. was followed by a sudden and unexpected thaw, followed by a great deal of rain. The last day of October was very fine; at night frost set in, and this morning (November 1st) 7° are registered. B. D., *S. Perthshire*.

— **A LARGE PORTUGAL LAUREL.**—A Portugal Laurel at Combermere Abbey, in Cheshire, is said to be at least 200 years old, and its branches have rooted in every direction. It has the appearance of being a large mass of shrubbery instead of a single Laurel. In places it is 30 feet high, and altogether it is 100 feet in diameter.

— **A MAGNIFICENT DOUGLAS FIR.**—A Douglas Fir was planted in the spring of 1842 at Waleot Park, the seat of the Earl of Powis, in Shropshire. This spring, after it had stood fifty years, it measured, says an exchange, 107 feet to the top of the leader, and at 4 feet from the ground the girth of its trunk was 12 feet 9 inches.

— **POTATO DISEASE IN THE MIDLANDS.**—It is reported that, in consequence of the recent excessive rains, disease has attacked the Potato crops in Huntingdonshire and Northamptonshire. Potatoes are extensively grown in these districts, and if the crops should fail, in addition to the bad harvest, the present agricultural depression will be increased.

— **TREES AND TREE PLANTING.**—At a recent meeting of the Wakefield Paxton Society, Mr. Wardman, The Gardens, St. John's, read a very useful and opportune paper on the above subject, in the course of which he pointed out the marked absence of taste and the meagreness of variety, with the consequent loss of effect, which is manifested in the planting of many gardens.

— **PYRETHRUM ULIGINOSUM.**—"H. W. W." does well to say a word in favour of this perennial. It is at the present time (October 15th) in splendid condition. We have clumps of it growing 8 feet apart down two sides of the kitchen garden, and being alternated with Michaelmas Daisies form quite a seasonable display with us, though the *Pyrethrum* grows over 7 feet high.—E. M.

— **CULTURE OF ONIONS.**—Mr. W. K. Woodcock, lecturer to the Norfolk County Council, recently dealt with the culture of Onions. He considered the Onion as ranking next to the Potato in importance as an article of consumption, and in its extensive cultivation. The manuring of the land, as in the case of the general cultivation of most crops, should be done in the autumn. Lime and soot dressings were invaluable at the proper season, in order to prevent or minimise the havoc caused by the maggot. The disease known as the "Onion mildew" was fully explained by Mr. Woodcock, and was shown to belong to the same species as the Potato disease (fungi family), and most prevalent in warm and moist localities. To prevent as far as possible the spreading of the disease, the dressing of the land with lime and the advantages of a rotation system of cropping were advocated.

— **DRYING FRUIT.**—It is singular that, while for many years the process of drying fruit has been carried on upon an enormous scale in the United States, the British fruit grower, although bewailing often the cost of carriage and the rapacity of the average middleman, has, so far, says a daily contemporary, taken no steps whatever to avail himself of a process by which he can diminish the freight to one-fifth eliminate the loss arising from damage during transit, and render himself altogether independent of Covent Garden. The recent Exhibition, before a number of fruit growers, at the Chiswick Gardens of the Royal Horticultural Society, of the work of a cheap and simple process for drying fruit will, it may be hoped, induce many of our fruit growers and farmers to consider the question seriously, and to give a trial to methods which have proved in America of such value alike to agriculturists and to the public. Enormous quantities of fruit are yearly wasted in this country simply because of the expense of getting to market, and the fact that there is at that season so great a glut that the prices obtained often hardly cover the cost of picking. For dried fruits, however, the demand would be steady throughout the year so soon as the public in general came to understand and appreciate its value for all culinary purposes. The carriage would be comparatively trifling, and the fruit should command prices very much more remunerative than when fresh. Naturally, the best kinds and varieties of fruit would still come to market, for these always command fair prices. It is for the cooking Apples, and for the varieties that are attractive neither to the eye nor the palate, that the drying process is peculiarly applicable.

— TECHNICAL EDUCATION IN HORTICULTURE.—We are desired to state that Mr. A. M. C. Jongkindt Coninck, late of the Nurseries, Dedemsvaart, Netherlands, is commencing a technical school at Bussum, near Amsterdam, which was opened on November 1st, for the thorough training of young gentlemen in horticulture in all its branches. Mr. Coninck, who is not unknown in England, bears a very high character; he is, we are authoritatively informed, well adapted for such work, for which he has already achieved a reputation.

— PLANTING TREES AT ROPNER PARK.—A pleasant function took place recently at the Ropner Park, Stockton. It was in connection with the planting of the first trees in the park. The cutting of the first sod was gracefully performed last year by Mrs. Ropner, whose husband (Major Ropner) is the munificent donor of the Park to the old Teeside borough. The first tree was planted by Mrs. Hind, wife of Alderman Hind, J.P., the Chairman of the Park Committee, and the lady was the recipient on the occasion of a pretty silver spade, the gift of Mr. James Watt, J.P., principal of the celebrated firm of Messrs. Little & Ballantine of Carlisle, nurserymen, and contractors for the planting of the park.

— NEW ZONAL PELARGONIUMS.—Messrs. Cannell's set of Zonals for 1893 will be found an exceptionally strong one, and lovers of these beautiful flowers should secure it in its entirety. It is composed of four raised at Swanley and several raised by Mr. Miller. The former are A. F. Woolton, a lovely light salmon with enormous pip, fine truss, and an excellent grower; Madame Melba, a most beautiful variety in the way of Lady Brooke, but a decided improvement on that charming sort, white, with the centre flushed delicate pink. It has a large round pip and a truss of great size. It forms a splendid floral prototype for the beautiful and gifted singer whose name it bears. Mascagni, named after the now famous composer, is a soft mottled salmon with a central ring of brilliant vermilion. It has a good habit, and is a fine grower. W. P. Wright is a powerful addition to the scarlets. It has a very large round pip, with broad overlapping petals, and is a dwarf sturdy grower. The others are all beautiful. Lord Tennyson is deep salmon; Picotee, mottled salmon with deeper picotee-like edge; and Double Guinea, light orange, are the three doubles. Three beautiful singles are the Rev. W. Bartram, brilliant scarlet; Blue Peter, purplish magenta, the nearest approach to blue yet secured; and Lady Dufferin, mottled salmon. The 1892 novelties are also lovely varieties. White Lady, snow white; Marquis of Dufferin, purplish magenta; Amphion, pink; Lord Idlesleigh, bright scarlet; and Inverness, salmon, are all conspicuous for round, smooth pips, and large trusses. Of the doubles, Colossus, a lustrous carmine-red seedling from F. V. Raspail; Sir Hamilton, purplish pink; Lady Lena, salmon, with light markings; and Miller's Gem, purplish magenta, and conspicuous for its light stems, are all acquisitions. In the superb collection of Zonals now in glorious bloom at Swanley the varieties named are conspicuously beautiful, while they are strengthened by the two varieties honoured by the R.H.S. a fortnight ago—Madame Bondeville and Improved Raspail.

— VEGETABLE NOVELTIES.—What are more dainty, says a ladies' contemporary, than well made croquettes of Potatoes fried until a pretty golden colour? If given even cold mutton for dinner, with Potato croquettes and a good salad, followed, perhaps, by a tasty dish of fresh Beans which have been simmered in a little butter seasoned with salt and pepper, and garnished with crisply fried sippets, one would not feel so inclined to grumble as when a cold joint is placed on the table with boiled Potatoes, the latter, perhaps, badly boiled, and French Beans dressed in the same way. A Vegetable Marrow, boiled, filled, when cold, with, say, a stuffing composed of scraps of cold meat or poultry well seasoned and mixed with bread-crumbs, or a thick, well-flavoured gravy, then rolled in flour, egg, and bread-crumbs, and fried a pretty golden colour, will make a dish which few people, if any, will not appreciate. Also it will use up scraps of meat which would probably be insufficient to make a dish of alone, as well as helping to free the bread-pan of stale pieces of bread, which, even in the best regulated of households, are apt to accumulate. The remains of a Cauliflower, if divided into small neat pieces, seasoned with a little minced parsley, salt, and pepper, then dipped into a light batter and fried, make an excellent dish, as does also the same vegetable simmered, or, more rightly speaking, braised, in a little stock. Of course all vegetables used should be freshly gathered. Cauliflowers and Cabbages will become fermented if kept long after they are cut, and thus an easily digested vegetable becomes just the reverse. Cabbage, in its various kinds and qualities, is grown as generally as Potatoes and Onions in all gardens, and as regularly boiled in our

kitchens. The idea of rubbing it through a sieve, as Spinach should be done, adding a little butter or even a small quantity of pork or beef dripping, a little grated cheese, salt and pepper, and beating all together, then serving it garnished with sippets and hard-boiled eggs divided into quarters, is never thought of. Little rolls of bacon daintily arranged round the Cabbage will make a dish more nutritious and certainly more appetising for lunch than many which are served, and the trouble and expense in preparing it are certainly not very heavy. Small cabbages blanched, the centres removed, and in the place a little minced meat, seasoned nicely, inserted, are excellent, if braised and served on squares of fried bread.

PILUMNA NOBILIS.

AMONGST the whole family of Orchidaceous plants fragrance in the flowers is more the exception than the rule, but with the above species there cannot be any misgivings as regards that matter, inasmuch as it is one of the strongest scented flowers in cultivation. The smaller *P. fragrans* is better known, but the one under notice is much the best. Out of three plants two of them are now in full bloom, and the other will follow quickly. Whether this must be regarded as the normal season of flowering I cannot say, as in other years with me they have bloomed in February and March; but this no doubt is the true season, the plants being very vigorous. Up to within the last two years I grew them in the Cattleya house, but they would not thrive at all well, the pseudo-bulbs getting gradually smaller. As a last resource the plants were placed in the cool house with the *Odontoglossums* when they commenced to improve at once, and which is evidently the proper position for them.

This is also an Orchid that does not like being unduly disturbed at the roots, and it thrives best in a well-drained pot. The material for growing it in should be good lumpy peat with fresh sphagnum, and firm potting is essential. During the growing season it requires a moderate amount of water, but after the pseudo-bulbs have formed the supply must be lessened, though not be kept wholly dry. It is upwards of four years since our plants were repotted, and as the compost is still sweet and the plants in a satisfactory condition, I shall not disturb them. The pure white and waxy looking flowers have a chaste and glistening appearance, with the exception of a yellow eye, which, however, enhances its effect.—A. YOUNG.

SOPHRONITES GRANDIFLORA.

THE plump growth of this pretty little winter-flowering Orchid will soon reveal its charming brilliant scarlet flowers, and assist with its dainty bits of colouring in enlivening the structure in which it is growing. I fancy the plants are often grown too cool, at least during the winter months, many growers thinking the cool house the best position for them the whole year round. During the summer months the cool house is undoubtedly the best position for them, the Cattleya house at this period being too warm and sunny. During the autumn and winter, however, the temperature of the Cattleya or intermediate house suits them the best. At least, I place our plants in the Cattleya house early in October and allow them to remain until April, when they are removed to the cool house. Under this treatment they do not degenerate. I have a number of plants, and some of the little specimens will produce a dozen flowers. The flowers also develop better in the Cattleya house and are a better colour. They are best cultivated in little pans and suspended near the glass. A plentiful supply of water is needed right throughout the growing season, and as the young growths develop with a flower it will be some time yet before the leaves become matured. After this takes place they must be kept fairly moist, over-dryness being fatal to their well-doing. They also require to be fixed firmly in the pans.—A. YOUNG.

PAPHINIA GRANDIS.

ALTHOUGH the proper name of this plant is *Lycaste grandis*, no doubt the name *Paphinia* will be the one used by horticulturists for a long time to come. The plant is a native of Brazil, and requires a stove temperature for its cultivation. The plants are small, but the flowers are large and fragrant. The pseudo-bulbs

are very short, surmounted by two or three leaves; the pendant scapes are produced from the base of the pseudo-bulbs, and carry two or three flowers, each from 4 to 6 inches in diameter. The sepals and petals are broadly lanceolate, their upper halves are purplish chocolate, and the basal halves dull creamy white, strongly blotched and barred with chocolate. The lip is small, three lobed; side lobes small and dull brown, centre lobe longer and spreading, bearing at the apex a large cluster of thick creamy hair. It

Glasnevin Botanic Gardens at Dublin, under whose care the above species (fig. 54) flowered for the first time in Britain in 1890. The home of this plant is not, we believe, exactly known, as it was bought by Mr. Moore, among other things, at a sale. A spike of thirteen flowers was exhibited by Mr. Moore at a meeting of the Royal Horticultural Society on Tuesday, March 22nd, of this year, when a first-class certificate was awarded it. The flowers are about 2 inches across on long pedicels;

FIG. 54.—MOOREA IRRORATA.

should be grown in peat and sphagnum, and suspended in baskets near the roof glass. When growth commences care should be taken not to allow any water to settle in the young growths or they will decay. Plenty of moisture should be given while growing freely, and previous to their flowering in October or November a sharp look out should be kept, or the scapes, which are produced so low down, will be lost by damping off.—C. K.

MOOREA IRRORATA.

THE genus *Moorea*, which is monotypic, was named by Mr. Rolfe of the Kew Herbarium after Mr. F. W. Moore of the

the spike is erect and stiff; the colour of the flowers is dull brown with a pale centre. There are but two plants of *Moorea* known in cultivation, one at Glasnevin and one in the Kew collection. The latter plant has six pseudo-bulbs 2 to 3½ inches long, dull green, and ribbed. Three of the bulbs have each a pair of leaves at the apex; the leaves are about 18 inches long and 4 inches broad at the middle, tapering at both ends, pale green, and stiff. It is in a small pot, and is growing well, so that at no very future date we may hope to have another opportunity of seeing this very interesting Orchid in flower.—C. K.

CHRYSANTHEMUM SHOWS.

THE following Chrysanthemum Shows, which have been advertised in our columns, will be held during the ensuing week. For the convenience of readers we append the names and addresses of the respective Secretaries. Those marked with an * opened on November 2nd, but will be continued to-day (Thursday).

- * Nov. 3.—Ascot, Sunningdale, and District. F. Patton, Ascot.
- * „ 3 and 4.—Portsmouth. F. Power, 20, Queen Street, Portsea, Portsmouth.
- „ 4 and 5.—Crystal Palace. W. G. Head, Crystal Palace, Sydenham.
- „ 4 and 5.—Bolton. J. Hicks, Markland, Hill Lane, Heaton, Bolton.
- „ 4 and 5.—Leeds Paxton. W. Appleby, The Grove, Headingley, Leeds.
- „ 8, 9, 10.—National (Royal Aquarium). R. Dean, Ranelagh Road, Ealing.
- „ 8 and 9.—Kingston and Surbiton. Geo. Woodgate, Warren House Gardens, Kingston Hill.
- „ 9 „ 10.—South Shields. Bernard Cowan, Horton, South Shields.
- „ 9 „ 10.—Bournemouth. Jas. Spong, Lindisfarne Gardens, Bournemouth.
- „ 10.—Calne. Fred. C. Henley, Calne.

REPORTS OF SHOWS.

DURING the Chrysanthemum season we are favoured with reports of many Shows. Several newspaper cuttings containing lengthy prize lists are also forwarded. These can seldom be used, we prefer short descriptive accounts with the names of prizewinners in the chief classes, also when practicable the names of the varieties in leading first prize stands. The co-operation of friends on the lines indicated will be much appreciated.

THE NATIONAL CHRYSANTHEMUM SOCIETY AND ITS CERTIFICATES.

I TRUST I may be permitted briefly to refer to the article under this heading on page 378 of your last issue for the purpose of throwing a little more light upon certain matters of fact.

1, In your second paragraph you seem to make it appear as if this was the first appearance of Beauty of Exmouth before the Floral Committee of the National Chrysanthemum Society. It was shown before that body by Mr. Godfrey on October 28th of last year, when the Committee wished to see it again in better condition. It was again submitted on November 10th, but not in condition to obtain a certificate. The Floral Committee, therefore, naturally expected it would come before them again this season, and their expectation was realised.

2, That a member of the Committee should have spoken disparagingly of the flower before it went before the Committee is regrettable; but I have observed the same at the meetings of the Floral Committee of the Royal Horticultural Society. As a member of the latter body I have been sometimes asked to look at a seedling and say whether it was in condition to go before the Committee for a certificate, and I have honestly advised the exhibitor not to prematurely damage the reputation of a good thing by presenting it in an undeveloped condition, but to grow it again another season, and show it in better form. It was, no doubt, with the same motive a member of the Floral Committee advised Mr. Godfrey to place Duchess of Devonshire "under the table." What I do warmly condemn is the expression I have heard from members of the Floral Committee of the R.H.S. and the N.C.S., "I have better than that at home," and I always protest against the use of such an expression.

3, There is nothing unusual or improper in a member of the Floral Committee opposing the granting of a certificate on the ground that the flower is not sufficiently distinct, and we have reason to be grateful to men having a particular knowledge for expressing this view. Having regard to the rapid rate at which new Japanese Chrysanthemums accumulate, it is very necessary the greatest check should be placed upon making records to varieties too much alike.

4, Mr. Godfrey was not appealed to in order to defend the distinctness of his flower. He was called forward by the chairman at my request to testify to Beauty of Exmouth being a *bonâ fide* English seedling; as the Committee unfortunately have knowledge of new continental and American varieties being palmed off as home-raised seedlings. The first vote was taken without some of the members being aware a certificate had been proposed, and some hesitated being desirous of testing whether Beauty of Exmouth was distinct from Florence Davis or not. A bloom of the latter was sent for, and I put the question to Mr. Godfrey, "Did he regard his variety as quite distinct?" and he answered, "Yes." The motion for a certificate was then put and carried by a large majority.

5, The matters in dispute between Mr. Godfrey and the "chief opponent of his blooms" I will not touch upon, they being *sub judice*;

but the occurrence illustrates the inconvenience resulting from permitting exhibitors to gather about the table at which the Floral Committee sit, and become listeners to what is said. The practice of the Committee has been so aboveboard, and has in consequence commanded so much confidence, as to encourage the sending to its meetings a very large and increasing number of new flowers for opinion, so that it rather courted publicity than otherwise. But the action taken by Mr. Godfrey in making public expressions intended only for the ear of the Committee, and in the confidence of privacy, has made it necessary that the meetings of the Committee shall be, as they were intended to be, strictly private; and for the future exhibitors and others not officially retained will have to withdraw, so that members of the Committee may feel at liberty to express themselves with freedom. The inception of the Floral Committee of the N.C.S. was largely my own, and had something to do with framing its rules and regulations. I have been a member of it since its formation, and have come to form a high opinion of its fairness and value. It is in this spirit I have penned the foregoing lines.

6, In conclusion I cannot but express my surprise that Mr. Godfrey made no complaint to me of what had occurred, though I conversed with him two or three times after the rising of the Committee. I think he should have addressed any complaint in the first instance to the Secretary of the Society.—RICHARD DEAN, *Secretary National Chrysanthemum Society*.

[Mr. Dean represents his view of the case with ability and an evident desire to be fair to all concerned. We have pleasure in publishing his communication, and have only a few small comments to append.

1, If Mr. Dean will read our "second paragraph" again he will find these words:—"We are informed that it had been previously exhibited."

2, That members of floral committees should speak disparagingly of flowers prior to their coming before them for adjudication is, as our correspondent states, most "regrettable," and the allegation that this is done at the meetings of the Royal Horticultural Society is obviously no justification of the practice wherever it may prevail. It is quite another thing when an exhibitor asks for friendly advice as to procedure, and we are quite sure this would be given with perfect honesty and no ulterior motive by our correspondent. We are also ready to believe with Mr. Dean that the advice given respecting the Duchess of Devonshire may have been on the lines he suggests.

3, Certainly there is nothing improper in a member of committee opposing the granting of a certificate; on the contrary, it is his duty to do so in accordance with his judgment so long as he is prompted by undoubted purity of motive. If he is animated by any other feeling, and especially if it has a bearing on his trade interests, every honourable man will admit that such an individual, whoever he may be, is unfit to serve on any committee of this nature whatsoever.

4, Our correspondent says Mr. Godfrey was "not appealed to in order to defend the distinctness of his flower." The words "on being appealed to" were written in our proof as a necessary correction by a high official of the N.C.S., though it is clear that Mr. Dean did not see them.

5, We concur in the expression relative to the inconvenience arising from the presence of exhibitors at committee tables, except for purposes of examination, and they should retire pending deliberations and decisions.

6, That is a question for Mr. Godfrey, but we think he is acquainted with a case that has been brought to the notice of Mr. Dean, in which a member of the Floral Committee threatens an exhibitor by letter that if he does not comply with a certain request he (the member) would take steps to prevent this trade exhibitor showing at the National Chrysanthemum Society. We also think Mr. Godfrey is aware that the officials declined to take cognisance of this case because it was of a personal nature. It was, and a great deal more besides, for it was a threat which could only have one tendency, viz., to injure a rival tradesman in his business.]

NATIONAL CHRYSANTHEMUM SOCIETY—OCTOBER 26TH.

AS is usual at the end of October a considerable number of new varieties of Chrysanthemums was submitted for examination by the Floral Committee at their meeting on the above date. Foremost came three of the fine seedling Japs raised by Mr. William Seward, The Firs, Hanwell, consisting of William Seward, a brilliant reddish crimson reflexed variety, which had already received an award of merit from the Royal Horticultural Society, and on this occasion was awarded a first-class certificate of merit, a variety that improves in point of size and colour; John Shrimpton, rich chestnut crimson, something of the colour of Cullingfordi, very bright, and a large and full reflexed Jap, also awarded a first-class certificate; Lizzie Seward, rich amaranth crimson with a silvery reverse, bright in colour and highly promising: the Committee wished to see it again. Mr. C. Blick, gardener to M. R. Smith, Esq., Hayes, Kent, and Mr. E. Beckett, The Gardens, Aldenham House, Elstree, both sent Japanese W. H. Atkinson, bright coral red and salmon, in some flowers deepening to cerise, novel and distinct in colour. The former received a first-class certificate of merit, his blooms being regarded as most developed, though the Aldenham flowers were rather the brightest. Mr. Beckett also had H. F. Jars, a bright Jap, which was commended for its colour.

From Mr. W. Herbert Fowler, Claremont, Taunton, came Mrs. Herbert Fowler, a very fine Jap, pale amaranth with silvery pink reverse, large and full; awarded a first-class certificate of merit. Mr. George Foster, Glendarragh Gardens, Teignmouth, sent W. H. Veale, a distinct sport from Sœur

Dorotheé Souille, in the way of Jean Marty, and a vote of thanks was awarded to him. From M. Ernest Calvat, Grenoble, came three new Japs.—viz., Madame Vivand Morel, a large creamy white incurved variety; Madame Rey, the basal florets deep pink with a light centre; and L'Isere, creamy white tinted with pink. It should be said that M. Calvat's method of packing, and the distance the blooms have to travel, militate against the flowers being put before the Committee under favourable conditions. A vote of thanks was accorded. From C. E. Shea, Esq., The Elms, Foot's Cray, came two Japanese varieties—viz., Gaetano Guelphi, a full ivory-white flower with a yellow centre, and Sylphide, yellow, bright in colour, and reflexed in the way of Sun-flower.

A number of new varieties was sent by Mr. H. J. Jones, Ryecroft Nursery, Lewisham. A first-class certificate was awarded to a plant of a dwarf growing decorative Jap named Ryecroft Glory, raised from seed sown in December, 1891, of a bright golden yellow colour, and singularly free; also to Jap Colonel W. B. Smith, a fine and striking flower of the Edwin Molyneux type, orange with golden reverse; very fine and distinct. Mr. Jones likewise had a white sport from Louis Boehmer, named Child of the Two Worlds, and Comte F. Lurani, the petals lined with white and pink like a Comet Aster, very pretty and distinct; both of which the Committee wished to see again. Several other new varieties were also staged by Mr. Jones. From Mr. W. Wells, Earlswood Nurseries, came a number of seedling single varieties, but to a considerable extent semi-double; several of them were bright in colour. Japanese John Dyer the Committee wished to see again. Mr. Wells also had a white sport from Vivand Morel, named Mrs. W. R. Wells, and it was said that it is characteristic of this variety to come white from an early bud. In proof of this Mr. Norman Davis sent two plants, each with three blooms; and in both cases one was rose coloured and the other two white. The Committee thought that under the circumstances it was inexpedient to recognise Mrs. W. R. Wells as a fixed white sport. A vote of thanks was passed to Mr. Wells for his collection.

Mr. C. Gibson, The Gardens, Morden Park, Mitcham, sent two new Japs—viz., La Belle d'Algers, a large reflexed variety, ivory flushed with pink; and Dey of Algiers, a large semi-double flower of the character of E. Molyneux. Messrs. Pitcher & Manda received a first-class certificate of merit for Japanese W. A. Manda as a hairy or spiny variety; large, and deep golden yellow in colour. This variety appears in the annual report of the Society as having been certificated last year; but was inserted in error. The same exhibitors also had Jap George Savage, white with primrose centre, which the Committee wished to see again; and some other varieties which will doubtless be seen later in better condition.

The following addition to Rule 3 was on the motion of the Secretary, seconded by Mr. George Stevens, unanimously adopted:—"And no persons but those officially retained are allowed to be present at the sittings of the Committee."

BIRMINGHAM CHRYSANTHEMUM SHOW AND THE DIVISION OF THE CUT BLOOM CLASSES.

MR. MOLYNEUX, in his remarks anent the Birmingham Show in the *Journal* for October 20th, says that it is very difficult to assign a reason for the division of the class for forty-eight cut blooms. He will, therefore, perhaps pardon me if I draw his attention to the *Journal* for March 10th last, where on page 185, he will find very tangible reasons given for the change—viz., to simplify the judging by placing Japanese against Japanese, and incurved against incurved, and to give increased opportunities to those exhibitors who cannot manage to stage a forty-eight stand, but who can manage a twenty-four, and this, too, without excluding those who can manage both. The Birmingham Committee certainly do not want to discourage the large growers, and surely these latter will not be afraid of the competition of the smaller ones.

I have no doubt that Mr. Molyneux can remember occasions when judging forty-eight-bloom classes—nay, and even when exhibiting himself—that if the first and second prize lot had been taken and divided into two classes, one of twenty-four Japanese and one of twenty-four incurved, and each section rejudged on their respective merits, he would sometimes have found that the first prizewinner in the forty-eight would not have been the first-prizewinner in both classes when divided in this way. It is not when one exhibitor's Japanese and incurved are superior to his opponent's that the difficulty in judging occurs, but when one is superior in Japs and the other superior in incurved, and yet so closely matched on the whole that it is difficult to see which is first. Then in that case much depends upon the relative merits of the two sections in the estimation of the judges. One may think there is nothing in the world like incurves, while the other may think there is nothing so graceful and beautiful as the Japanese, but when the competition is respectively confined to each section, then it is immaterial which is the greatest favourite with the judges.

After twenty years' experience in the management of Chrysanthemum shows I am thoroughly convinced that the more distinctly the various sections are classified, and the less they are mixed up, the greater will be the competition, the more simple the judging, the greater satisfaction prevail amongst the exhibitors when the judging is completed, and the more likely will the successful exhibitors be able to see the points by which they have won and the unsuccessful ones why they have lost, the latter especially being very important if harmony is to prevail. For any show to be a success committees should, in framing their schedules, first offer the largest possible prizes their means will allow; secondly, open the widest field possible for competition; thirdly, so classify the exhibits

that the judging shall be as simple as possible; and, lastly, make the conditions so clear and distinct that it shall be impossible not to understand them. This done, with good management, success is sure to follow. We in Birmingham, although successful, do not pretend to be infallible, but content ourselves that time will prove all things.—J. HUGHES.

THE SHOW BOARD CONTROVERSY.

I HAVE read with much interest the remarks of "A. D." (page 379, *Journal of Horticulture*) touching his interview with Mr. George Woodgate with reference to the above question. It must not be inferred from the fact that I prepared a paper (by request) for the recent Conference of the National Chrysanthemum Society, advocating the enlargement of the show board for Japanese Chrysanthemums, that I am indifferent to the considerations urged by "A. D." and the Secretary of the Kingston Chrysanthemum Society. On the contrary, so strongly do I feel that the undue preference often given at our shows to mere size directly tends to banish from the exhibitor's collection many of the most refined and beautiful varieties, merely on account of their relative smallness, that I have no hesitation in saying that if the alternatives must be either to part with these varieties in order to make room for a sufficient army of the "big ones" or to discontinue showing altogether, the latter alternative ought to be accepted. In theory we know that a perfect bloom of Criterion is supposed to receive as much consideration as an equally fine flower of Vivand Morel, but who, may I ask, would have the hardihood to put this theory into practice on a stand of twelve blooms? But while claiming justice and equality for the smaller varieties, we must not accord other treatment to their larger rivals. I suppose that it will be generally conceded that it is idle, if indeed it were desirable, to seek to exclude the modern race of giants from the exhibition tables—as well might we try to induce water to run up hill. And if their exhibition be admitted, the stands upon which they are to be presented to the judge must be large enough to permit of a really effective judgment. If it be conceded (and the late Conference considered the point to be established) that the show boards originally designed for the incurved section are inadequate for the requirements of the present day race of Japanese blooms, then minor considerations must be subordinated, and an essential of effective judging must not be refused because the so-called "concession" may be thought to have the indirect effect of "putting a premium on size and breadth at the expense of depth, refinement, and beauty."

Passing by the question whether "depth" will not, in fact, be better estimated upon a board whereon the blooms stand free, I must reply that the salvation of the smaller varieties must rest upon some other and better basis than the refusal of a needed reform to a large and constantly increasing class of exhibition blooms. That every effort should be made to retain such gems as Criterion, Florence Percy, the Lacroix family, and Martha Harding, I am strongly of opinion, and whether the proposals of Mr. Woodgate would serve to ensure this result is a question well worthy of consideration. Certainly a practical step in the right direction has been taken in the decision of the N.C.S. to require "distinct" varieties in the class for forty-eight Japanese. This must serve to bring back many varieties which have almost disappeared from the exhibition tables, but necessarily the effect of this regulation will be limited to those who contemplate competition in this particular class, and something further is certainly required, but while this "something" is being sought for I think that it would be impolitic and unwise to seek to make the matter in any way dependent upon the question raised in this discussion. The cause of the smaller varieties can well afford to stand on its own intrinsic merits.

Of course it is not necessarily incumbent on the Kingston Chrysanthemum Society to adopt the results of the N.C. Society's Conference, but it is obviously desirable that uniformity of practice upon the subject should, if it be possible, prevail throughout the country. That the Committee of the National Chrysanthemum Society will adopt the practically unanimous decisions of the Conference which itself had called, I may infer as a safe conclusion, otherwise one would scarcely realise the meaning and utility of the gathering of the Conference at all.

The suggestion that a stand of the proposed new regulation size, filled with appropriate blooms, should be exhibited at the leading Chrysanthemum shows next month is a good one, and I hope to see it generally adopted.—CHARLES E. SHEA, *The Elms, Foot's Cray, Kent*.

CHRYSANTHEMUM SHOWS AND GARDEN CHARITIES.

YOU gave last week a list of no less than eighty-seven Chrysanthemum shows, most of them of two days duration, which will be held during the present month. Very probably there are some forty or fifty more smaller ones that do not get so much notice. But supposing the shows reach a hundred, here is a field which it does seem ought to be worked in the interest of our garden charities. Why, if each show could be made to produce only £2 that would give £200 to be divided between the Gardeners' Benevolent and the Gardeners' Orphan Funds. That seems to be, however, a very low average, and did the hundred of exhibitors only return to the Fund's boxes, or through the local secretaries, 3 per cent. of their winnings in the respective competitions, the sum named would be doubled. When I was in Mr. H. J. Jones' fine show house of Chrysanthemums last week at Lewisham he showed me collecting boxes for the Orphan Fund fastened on to the respective doors, and told me that in the case of mere visitors, and not customers, he drew their attention to the boxes in the hope that they would make some little contribution. What he does many others could do; in fact, in hundreds of private places Chrysanthemum collec-

tions might be thrown open to the public expressly to aid the garden charities. It is too late to work this field fully this season perhaps, but local or show committees and private or trade growers may take the hint now and accomplish something. The time for the election of candidates on to the Funds is coming near, and the greater the pecuniary help the more candidates can be elected.—A. D.

Calls on Celebrities.

ON the eve of the Chrysanthemum season its prospects are always discussed with interest, and the condition of each grower's plants is a matter of lively speculation; a *Journal* representative has therefore made calls on some of the leading growers, with a view to gathering readable information for the benefit of fellow cultivators. He finds a general complaint that the plants are late, but everything points to a season of quite average excellence, and of more than average interest. The number of new varieties is greater than ever. The air is full of rumours about extraordinary novelties, but that is a chronic condition after all. The American, French, and German contributions are liberal to a degree, and there will also be a considerable number of British seedlings to take stock of. The latter is a welcome feature, and the products of home hybridisation will be looked for with special interest.

MR. H. J. JONES.

If there is one man in the Chrysanthemum world more than another who may view his work with pride it is Mr. H. J. Jones. A little boastfulness might even be pardonable in the face of what he has accomplished, but Mr. J. is as modest as he is able, and leaves others to do the praising. So extraordinary has been the growth of his business and the development of his collection that it might almost be styled phenomenal. Two grand houses, each 103 feet long by 25 feet wide, are filled with plants in robust health. The structures are of a most substantial character, and the system of ventilation is a splendid one. The main show house now contains about 3500 plants, arranged in two broad banks, with a central path between them, and the effect they produce may almost be described as magnificent even at this early period. What it will be about the middle of November every Chrysanthemum lover should see for himself. The Ryecroft Nursery is at Hither Green, Lewisham, and a very good way of getting to it is to take the train to Lewisham Junction from Charing Cross, Cannon Street, or London Bridge, then walk or take the tram to Hither Green. A few minutes suffice in either case. Mr. Jones has not been settled there long, but his place is already famous, and there is no difficulty in finding him. During the years that he has been struggling for the position in the Chrysanthemum world there is one thing that his worst enemy could never deny him, and that is the credit of being a tremendous worker. His career has been chequered, but through good and evil report he has striven hard and unceasingly; all the more pleasant is it therefore to record that fortune is now carrying him forward to such brilliant success.

All that money, work, and energy can do to get a complete collection of Chrysanthemums together is being done by Mr. Jones. He has all the leading varieties, together with a large number of novelties. The season being somewhat late, many of the best kinds were not out at the time of our representative's call; nevertheless, there was plenty to admire. It will be more interesting, no doubt, to make a few brief references to the novelties than to devote space to the varieties which are familiar. Mr. J. Lyne will perhaps be considered an improved Mons. Elliott. It is a dwarf, strong grower, with large bronze coloured flowers. White Louis Boehmer at once arrests attention. Mrs. Alpheus Hardy has given us a considerable amount of trouble, but here we have a pure white with hairy florets having the sturdy growth and strong constitution of the "pink Ostrich Plume," and there is no doubt that a great demand will spring up for it. Mr. Jones has a good many plants, and the character is the same in them all. President Carnot is a promising incurved. It was sent out as a crimson, but that colour is in the upper surface of the petal and hidden through the incurving; the flower appears, therefore, as a greyish buff. It is large and massive. Mrs. Harman Payne, a deep rose Japanese, is coming very fine, and another most promising variety of the same section is Comte F. Lurani, which has long broad pale florets with a rosy lilac margin, and is dwarf and sturdy. Ethel Paul (J), though one of the now numerous army of whites, is distinct in character, having broad incurving florets. Sylphide (J), is notable for its beautiful and perfectly distinct shade of yellow, which charms everyone who sees it. Amos Perry (J), is another promising yellow. It is of the character of Coronet, but comes better. Ami Jules Chrétien (J), is noteworthy from its rich maroon colouring. Ryecroft Glory (J), will prove to be a leading market sort. It is dwarf and bushy, with abundance of bright yellow flowers. It was in bloom seven weeks ago, and now has an abundant second crop. The seed was sown on the 2nd of February. Mons. Bredernier (J), is a rich carmine flower, and Gaetano Guelphi (J), a fine white with curled florets. The "yellow Laeroix," Mr. C. E. Shea, is in fine condition. It is remarkable, like the old white, for its freedom of blooming. Colonel Smith was not fully out, but was giving rich promise of future excellence, and the same may be said of J. Stanborough Dibben, a wonderfully dwarf and sturdy grower. Miss Watson (J), is a yellow with the characters of Avalanche.

These are but a few out of many. Let everyone who has an opportunity or can make one go and see for himself what Mr. Jones is doing. A visit will be richly repaid, and the general verdict will probably be that the Lewisham grower has secured a long lead amongst metropolitan Chrysanthemum growers.

MESSRS. REID & BORNEMANN.

Trewsbury Road is a broad and pleasant thoroughfare, half a mile, or a little less, from Sydenham station, and in it is situated the nursery of Messrs. Reid & Bornemann, who have in a very short time made themselves a reputation in the Chrysanthemum world. They began with ideas of grouping which differed from those usually prevailing, and success smiled upon their efforts to carry them into effect from the first. They believed, for one thing, in quality of bloom, which to many had been a consideration of very little importance. Thus not only were their plants always effectively arranged, but there was something in the groups which repaid a close as well as a general survey. Next they attached due weight to finish. Instead of a "beggarly array" of bare stems in the front, their groups were conspicuous for lines of dwarf plants 1 to 2 feet high, well clothed with foliage and carrying excellent flowers. These imparted an appearance of completeness which was at once pleasing and natural. Their good deeds of this nature were rewarded with a shower of first prizes and a reputation that has doubtless proved still more valuable to them.

Messrs. Reid & Bornemann grow about 2500 plants, to afford selections for showing. This may seem a very large number, considering that they practically restrict themselves to grouping; but they have a very good foreign connection, and at the present time have four important continental exhibitions to engage their attention apart from those which they will compete at in England. They have several houses of plants, and assuredly will be even harder to beat this season than they have been previously, for they have a great variety of material, admirably grown, and carrying fine flowers. The exhibitor who sets up a group good enough to defeat them will achieve a noteworthy feat. The *Journal* representative paid a somewhat early visit, and the collection was not, therefore, in full flower; but there were many new and old varieties, either open or opening. One of the specially good things of the collection was Gloire du Rocher, which has turned out to be a splendid acquisition. It is a fine grower, and the beautiful chestnut red flowers have a very marked individuality. Avalanche is good, as usual—dwarf, sturdy plants, bearing beautiful blooms. Hamlet, with its distinct rosy-red flowers, very freely produced, is also noteworthy. W. H. Lincoln is very fine; it is a dwarf strong grower, may be had either in September, October, or November, and is rapidly earning the character of being the best yellow Japanese in cultivation. Alberic Lunden is another sterling acquisition; it is carrying some splendid blooms, and the rich purplish crimson hue is most effective; Vivian Morel and Jeanne Délaux are coming on well, and so is Mr. A. H. Neve; Vivian Morel has white and pink flowers on the same plant, the former being produced by the early bud; Sunflower and Etoile de Lyon are two other old varieties that promise well; and W. Tricker should be noted as consistently good—it is a valuable early bloomer, and one of the most useful of all the Japanese. The dwarf plants so effectively used by the firm are looking remarkably well. They range from 6 inches to 2 feet high, and have excellent flowers. Val d'Andorre, Avalanche, Mons. Freeman, Gloire du Rocher, E. Molyneux, and Alberic Lunden are amongst the best of them.

The new varieties are very numerous and of the usual character, a few good, many moderate, some bad; a few of the most promising ones which are well worth further trial, are noted. W. Roessing is a pure white Japanese of great size with very broad florets. Director Kowallek, a tall incurved Japanese, white flaked with rose, may prove to be good. Uranus and Mons. J. Moulins are decorative varieties with divided antler-like florets, the former white, the latter light chestnut. Colonel Smith is the best of all the novelties, it is a real acquisition. It will be remembered as a large Japanese with distinct bronzy amber flowers exhibited a year or two ago. It is very vigorous, its only fault being too tall growth. Madame Léon Hasse is a decorative Japanese with long slender pointed florets of a tawny bronze hue. Duchess of Anhalt Dessau is a seedling Japanese of Messrs. Reid and Bornemann. It is of the Condor and Etoile de Lyon type, having long broad florets, white with a rosy purple margin. Madame Elizabeth Labah is a creamy Japanese with very large flowers, and Belle Hickey is a promising American importation. It is a pure white Japanese with narrow incurving florets, is an excellent grower and blooms freely.

MESSRS. CANNELL & SONS.

A home for flowers would be a dull and cheerless one at this season of the year if it contained no Chrysanthemums, and as that at Swanley is never dull and never cheerless it goes without further saying that they are well represented. Messrs. Cannell & Sons are not in the habit of doing things by halves, and they have taken a bold step in the erection of a splendid show house 160 long by 25 feet wide. This being now full of plants is merging into a dream of beauty. There are over 3000 of them in robust health and developing fine blooms. The season is late, and so the flowers were backward on an early call being made, but many were open or opening.

The king of the novelties beyond all doubt was Colonel Smith, which Messrs. Cannell sent out a year or two ago. It is a Japanese of commanding excellence, the growth being very sturdy, the height medium, the flowers large, and the florets a beautiful bronze hue tipped with gold. It is one of the greatest acquisitions of recent years. The Swanley growers have a large stock of it, and the plants arranged here and there in the collection all stand out distinct and effective. Mrs. Harman Payne (J.) is a dwarf strong grower, and is bearing some fine blooms. The colour is rosy lilac, the outer surface of the florets rosy mauve. Mohawk (J.), a dwarf American with bronzy flowers, seems

likely to turn out good. Mrs. G. W. Childs (J.), brownish crimson with bronzy red reverse, is very rich in colour and decidedly effective. Madame Ed. Rey is an incurved of great promise. The colour closely resembles that of Hero of Stoke Newington, but the flower is much larger and is very conspicuous for the great breadth and substance of the petals. It is one of Calvat's, and may prove an acquisition; certainly it is well worth further trial. Otto Bollif (J.) is in the style of Marsa, a large flower, rosy mauve in colour, with numerous splashings. Delaware (A.) has been seen on several occasions, and its merits are becoming pretty well known. At Swanley it is splendid. The pure white flowers with their lemon centre are of the largest size. L'Ami Etienne (J.-i.) is another very promising variety of Calvat's raising. The flowers are large and of a delightful silvery blush shade. President Borrel (J.) comes from the same grower and has deep rose flowers. Julius Roehrs (J.) is an American of dwarf growth and with large flowers of a bright carmine rose colour. Noel Pragnell (i.), the "Striped Empress," is a pleasing bloom with mauve flakings along the petals, but is hardly likely to become very popular. One good self is worth twenty mixtures. Robert Cannell (J.-i.) is represented by some very fine blooms. Its brownish bronze flowers are now pretty familiar, and they are very effective in a mixed collection. Mrs. H. W. Goulden (J.-i.) will strike most persons as a charming flower, its silvery blush hue being most distinct. Perhaps its colour may be a little too delicate for some, but be that as it may we can very well do with some more refined colours. Lilian Russell (J.) is an American with rich mauve flowers that is very likely to secure a prominent place. Charles Gongnon (J.) is a flower of the Lady Selborne type, but the colour is a reddish bronze. Mrs. J. S. Fogg, the yellow Japanese which Mr. Blair showed so well last year, is noteworthy. It is pretty certain to be seen in several prize stands this season. Anna Dorner (J.) is another of the Trans-atlantic contingent. It is a dwarf strong grower and the colour is as near cream as anything else, perhaps a little nearer. Kentish Yellow, the "Yellow Elaine," is very bright and effective. Hetty Dean (J.) is a white sport from President Hyde. Amos Perry (J.) is so promising that it appears likely to secure a high place among the yellows, and we are now getting so many of these that commoners will have no chance. Golden Ball looks like turning out especially valuable for specimens from its style of growth and blooming. John Dyer (J.) is a very large and fine bronze variety that growers will probably find themselves able to utilise with advantage. Mdlle. Marie Recoura (J.) is a fine white of the Etoile de Lyon type, and Vice-President Calvat (J.) is a very large rich crimson.

The two bright particular stars of the collection among the other varieties were Vivand Morel and W. Tricker. Grand variety as the former is it is almost eclipsed by the American. Both are very dwarf and sturdy growers, bear large massive blooms of great depth, and are pleasing in colour. There is no doubt whatever that W. Tricker is not only one of the first Japanese of recent introduction, but one of the most valuable varieties in cultivation. It appears to be consistently good everywhere. It is almost superfluous to dwell on the character of Messrs. Cannell's plants, for good culture reigns supreme in every department at Swanley, and it is hardly likely that an exception would be made with the Chrysanthemums. They are indeed fine, and a credit to the growers. The standing invitation is "Come and see," and whoever responds will find in the Chrysanthemums and the magnificent display of Zonals a sufficient reward, even if he travelled from the uttermost end of the country.

MR. W. PIERCY.

Mr. Piercy's speciality is early bloomers, and in the small structure on his premises at Beadnell Road, Forest Hill, he has, and has had for a considerable time past, a very brilliant display. He takes pains to keep his collection up to date, so that a visit to him is always repaid by an inspection of the newest and best varieties in the early flowering section. He is out of all sympathy with disbudding, and his plants are all full of bloom, which is valuable for making his house gay, and also for cutting. The demand for cut Chrysanthemums is now so great that there is very little doubt that the culture of select early varieties for supplying the want indicated could be made a profitable proceeding.

Amongst the best varieties in Mr. Piercy's collection were the following:—Gustave Gruenewald, figured in the *Journal* a few weeks ago; it has been in bloom since May, and will probably prove a great acquisition; Georges Devered, a beautiful yellow Japanese that has also been flowering since May; Mdlle. Renée Cohn, a new and very promising pale rose Japanese; Mons. G. de Duber, bronzy yellow, in the way of Pynaert van Geert, but freer; Ruby King, light brownish red, dwarf, robust, and free, early, and likely to prove valuable for market; Mrs. Hicks Arnold, soft lilac, a most profuse bloomer; O. J. Quintus, rosy mauve, the plant a mass of bloom, this variety is now well known; Madame Dufossé, bronze, very free, a fine decorative variety; Carry Denny, bronzy yellow, full of bloom; Souvenir de M. Menier, fine dark crimson; Eulalie Morel, rosy lilac Japanese, plants were blooming in August from cuttings inserted in April; Henri Devered, bronzy yellow, bloomed in August from cuttings struck on May 5th; Harvest Queen, a useful white market Pompon; Mons. Jacob, crimson reflexed; and Maxime de la Rocheterie, light bronzy chestnut, a fine full bloom.

Mr. Piercy has worked well to popularise the class of his choice, and deserves the gratitude of all Chrysanthemum lovers.

VIVAND MOREL.

As there appears to be several sports about of this beautiful variety I herewith send you a partly expanded bloom (which has, unfortunately, commenced to damp) of a sport which has made its appearance in these

gardens. I saw Mr. Wells' plant at the National, and I think this is more of a primrose shade than the one shown by him. I hope to grow some good blooms of it next season.—G. TRINDER, *Dogmersfield Gardens, Winchester.*
